Abstract

Two-dimensional real hyporeductive triple algebras (h.t.a.) are investigated. A classification of such algebras is presented. As a consequence, a classification of two-dimensional real Lie triple algebras (i.e. generalized Lie triple systems) and two-dimensional real Bol algebras is given.

Keywords: Hyporeductive algebra, Bol algebra, Lie triple algebra, Lie triple system, smooth loop.

2000 Subject Classification : Primary 17D99.

1. Introduction. Hyporeductive algebras were introduced by Sabinin L. V. ([7, 8]) as an infinitesimal tool for the study of smooth hyporeductive loops which are a generalization both of smooth Bol loops and smooth reductive loops (i.e. smooth A-loops with monoalternative property [8]). It is shown that the fundamental vector fields of any smooth hyporeductive loop constitute an algebra called a hyporeductive algebra of vector fields. Further (see [1, 2, 7]) this notion has been extended to the one of an abstract hyporeductive triple algebra (h.t.a. for short) meaning a finite-dimensional linear space with two binary and one ternary operations satisfying some specific identities. It turns out that hyporeductive algebras generalize Bol algebras and Lie triple algebras (see [10, 12] about Bol and Lie triple algebras).
In this paper we consider 2-dimensional h.t.a. over the field of real numbers (i.e. 2-dimensional real h.t.a.) and the search of clear expressions of operations for such algebras led us to their classification (such a classification includes the one of 2-dimensional real Lie triple algebras, Lie triple systems and Bol algebras).

Petersson H. P. [6] solved the classification problem for 2-dimensional nonassociative algebras over arbitrary base fields, and in his approach structure constants or multiplication tables almost never play a significant role. Underlying this classification is the use of an isomorphism theorem and the principal Albert isotopes. One observes that the algebras considered in that paper are binary algebras. It seems that the Petersson approach is not applicable to the case of 2-dimensional h.t.a. because of the following reasons. First, h.t.a. are contained in the class of tangent structures with one (or more) binary operations and a ternary operation (this is why they are usually called binary-ternary algebras) satisfying some compatibility conditions. Thus, if the Petersson approach could be applied to the binary operations of h.t.a. (under some conditions), it does not work, in general, for the ternary operation of h.t.a. (for instance, we still do not know what is the principal Albert isotope of a ternary operation of an algebra). Next, even for Bol algebras which are a very particular instance of h.t.a., almost no classification results are known (the classification of 2-dimensional real Bol algebras given in the present paper seems to be, to our knowledge, the first one so far). Because of the nature of h.t.a., their classification over arbitrary base fields should generalize, e.g., the one of Bol algebras over arbitrary base fields but, unfortunately, the latter is still not available in litterature. The other reason for considering in this paper only real h.t.a. is related to the correspondence between h.t.a. and smooth hyporeductive loops ([9]) (this problem is solved by Kuz’min E. N. [5] for real finite-dimensional Malcev algebras and smooth Moufang loops and by Sabinin L. V. and Mikheev P. O. [10] for real finite-dimensional Bol algebras and smooth Bol loops).

In Section 2 some results on hyporeductive algebras are recalled and the classification theorem is stated. The section 3 deals with its proof (this proof gives the classification strategy).

2. Background and results. Hyporeductive algebras were originally introduced ([7, 8]) as algebras of vector fields on a smooth finite-dimensional manifold, satisfying a specific condition. More exactly it was given the following

**Definition 1** [7, 8]. A linear space $V$ of vector fields on a real $n$-
dimensional manifold $M$ with a singled out point $e$, satisfying

$$[X, [Y, Z]] = [X, a(Y, Z)] + r(X; Y, Z)$$

is called a hyporeductive algebra of vector fields with determining operations $a$ and $r$, if $\dim\{X(e) : X \in V\} = n$.

Obviously $a(Y, Z)$ is a bilinear skew-symmetric operation and $r(X; Y, Z)$ a trilinear operation on $V$, skew-symmetric in the last two variables. We called the relation (1) the hyporeductive condition for algebras of vector fields (see [1, 2]). Considering a hyporeductive algebra as a tangent algebra at the identity $e$ of a smooth hyporeductive loop it is shown ([7, 9]) that a hyporeductive algebra may be viewed as an algebra with two binary operations $a(X, Y)(e)$, $T_e(X, Y) = [X, Y](e)$ and one ternary operation $r(Z; X, Y)(e)$ and then, working out the Jacobi identities in the corresponding enveloping Lie algebra, one can get the full system of identities linking the operations $a, T_e, r$. A similar construction is carried out in [1, 2], where instead of $T_e(X, Y)$ the operation $b(X, Y) = [X, Y](e) - a(X, Y)(e)$ is introduced (this is made in connection with a more suitable differential geometric interpretation of a hyporeductive algebra of vector fields and then the system of identities mentioned above constitutes the integrability conditions of the structure equations of the affinely connected smooth manifold associated with a local smooth hyporeductive loop). If define the operations $X \cdot Y = a(X, Y)(e), X * Y = b(X, Y)$ and $\langle Z; X, Y \rangle = r(Z; X, Y)(e)$, then $(T_e M, \cdot, *, \langle ; , \rangle)$ is an algebra satisfying the system of identities mentioned above. This led us to introduce the notion of an abstract hyporeductive triple algebra (h.t.a.):

**Definition 2 ([1, 2, 3]).** Let $V$ be a finite-dimensional linear space. Assume that on $V$ are defined two binary skew-symmetric operations $\cdot, *$ and one ternary operation $\langle ; , \rangle$ skew-symmetric in the last two variables. We say that the algebra $(V, \cdot, *, \langle ; , \rangle)$ is an abstract h.t.a. if, for any $\xi, \eta, \zeta, \kappa, \chi, \theta$ in $V$ the following identities hold:

$$\sigma \{ \xi \cdot (\eta \cdot \zeta) - \langle \xi; \eta, \zeta \rangle \} = 0,$$

$$\sigma \{ \zeta \ast (\xi \cdot \eta) \} = 0,$$

$$\sigma \{ \langle \theta; \zeta, \xi \cdot \eta \rangle \} = 0,$$

$$\kappa \ast \langle \zeta; \xi, \eta \rangle - \zeta \ast \langle \kappa; \xi, \eta \rangle + \langle \zeta \ast \kappa; \xi, \eta \rangle =$$

$$\langle \xi \eta; \zeta, \kappa \rangle - \langle \zeta \ast \kappa; \xi, \eta \rangle$$
\[
\chi \cdot (\kappa \cdot \langle \zeta; \xi, \eta \rangle) - \langle \chi; \xi, \eta \rangle - \langle \chi; \zeta; \xi, \eta \rangle + \langle \chi; \zeta, \xi, \eta \rangle = 0,
\]
\[
\xi \cdot (\kappa \cdot \langle \zeta; \xi, \eta \rangle) - \zeta \cdot (\kappa \cdot \xi; \eta) + \langle \zeta; \kappa; \xi, \eta \rangle = 0,
\]
\[
\eta \cdot (\kappa \cdot \langle \zeta; \xi, \eta \rangle) - \zeta \cdot (\kappa \cdot \xi; \eta) + \langle \zeta; \kappa; \xi, \eta \rangle = 0,
\]
\[
\langle \theta; \chi, \kappa \cdot \langle \zeta; \xi, \eta \rangle \rangle - \langle \theta; \kappa \cdot \langle \zeta; \xi, \eta \rangle \rangle = 0,
\]
\[
\Sigma \{ \langle \langle \eta; \zeta; \kappa \rangle, \xi \rangle - \langle \langle \eta; \zeta; \kappa \rangle, \xi \rangle \rangle \ast \lambda \}
\]
\[
\Sigma \{ \langle \langle \mu; \xi; \zeta \rangle, \kappa \rangle - \langle \langle \mu; \xi; \zeta \rangle, \kappa \rangle \rangle \ast \mu \} = 0,
\]
\[
\Sigma \{ \langle \theta; (\langle \mu; \xi; \zeta \rangle, \kappa \rangle - \langle \langle \mu; \xi; \zeta \rangle, \kappa \rangle \rangle, \lambda \rangle
\]
\[
+ \langle \theta; (\langle \lambda; \xi; \kappa \rangle, \eta \rangle - \langle \lambda; \xi; \zeta \rangle, \xi \rangle, \mu \rangle \} = 0,
\]

where \(\sigma\) denotes the sum over cyclic permutations of \(\xi, \eta, \zeta\) and \(\Sigma\) the one on pairs \((\xi, \eta), (\zeta, \kappa), (\lambda, \mu)\).

**Remark 1.** The study of h.t.a. is more tractable if they are given in terms of identities as in the definition above. For instance, we observe that if in (2)-(13) we set \(\xi \cdot \eta = 0\) for any \(\xi, \eta\) of \(\mathcal{V}\), then we get the defining identities of a **Bol algebra** \((\mathcal{V}, \ast, \langle ; ; \rangle)\):
\[ \sigma \{ \langle \xi; \eta, \zeta \rangle \} = 0, \]
\[ \langle \xi \ast \eta; \zeta, \kappa \rangle - \langle \zeta \ast \kappa; \xi, \eta \rangle + \zeta \ast \langle \kappa; \xi, \eta \rangle - \kappa \ast \langle \zeta; \xi, \eta \rangle + \langle \xi \ast \eta \rangle = 0, \]
\[ \langle \langle \chi; \xi, \eta; \zeta, \kappa \rangle \rangle - \langle \langle \chi; \zeta; \xi, \kappa \rangle \rangle + \langle \chi; \zeta, \langle \kappa; \xi, \eta \rangle \rangle = 0. \]

From the other hand, setting \( \xi \ast \eta = 0 \), we get a Lie triple algebra (i.e. a generalized Lie triple system) \((\mathcal{V}, \cdot, \langle \cdot, \cdot \rangle)\):
\[ \sigma \{ \xi \cdot (\eta \cdot \zeta) - \langle \xi; \eta, \zeta \rangle \} = 0, \]
\[ \sigma \{ \langle \theta; \zeta; \xi \cdot \eta \rangle \} = 0, \]
\[ \kappa \cdot \langle \zeta; \xi, \eta \rangle - \zeta \cdot \langle \kappa; \xi, \eta \rangle + \langle \zeta \cdot \kappa; \xi, \eta \rangle = 0, \]
\[ \langle \langle \chi; \zeta; \xi, \kappa \rangle \rangle - \langle \langle \chi; \zeta; \kappa, \xi \rangle \rangle + \langle \chi; \zeta, \langle \kappa; \xi, \eta \rangle \rangle - \langle \chi; \zeta, \langle \kappa; \xi, \eta \rangle \rangle = 0 \]
and if, moreover, we put \( \xi \cdot \eta = 0 \) then we obtain a Lie triple system (L.t.s.) (see Yamaguti K. [11]). Note that for \( \xi \ast \eta = 0 \) and \( \xi \cdot \eta = 0 \), the identities (9)-(13) hold trivially.

The question naturally arises whether there exist proper abstract h.t.a. The answer to this problem is easier to seek among low-dimensional h.t.a. because of the specific properties of operations \( " \cdot \", " \ast " \) and \( \langle \cdot, \cdot \rangle \). Thus we are led to the study of two-dimensional real h.t.a. that is, to find the clear expressions of their defining operations. The following classification theorem describes, up to isomorphisms, all 2-dimensional real h.t.a. Such a classification includes the one of 2-dimensional real Bol algebras, Lie triple algebras and Lie triple systems.

**Theorem.** Any 2-dimensional real h.t.a. is isomorphic to one of the h.t.a. of the following types:

(I) \( u \ast v = 0, u \cdot v = 0, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku - ev, \)

(II) \( u \ast v = 0, u \cdot v = au, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = ku, \)
\( (a \neq 0), \)

(III) \( u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = 0, \)
\( (a \neq 0, b \neq 0), \)

(IV) \( u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku - ev, \)
\( (a \neq 0, b \neq 0, e \neq 0, f \neq 0, k \neq -e, af - be = 0 = bk + ae), \)

(V) \( u \ast v = cu + dv, u \cdot v = 0, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku - ev, \)
\( (c, d) \neq (0, 0)), \)

(VI) \( u \ast v = cu + dv, u \cdot v = au, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = ku, \)
\( (a \neq 0, (c, d) \neq (0, 0)), \)

(VII) \( u \ast v = cu + dv, u \cdot v = au + bv, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku - ev, \)
\( (a \neq 0, b \neq 0, e \neq 0, f \neq 0, k \neq 0, (c, d) \neq (0, 0)), af - be = 0 = bk + ae), \)

(VIII) \( u \ast v = cu + dv, u \cdot v = au + bv, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = 0, \)
\((a \neq 0, b \neq 0, (c, d) \neq (0, 0))\),
where \(a, b, c, d, e, f, k\) are real numbers.

**Remark 2.** The algebras of types (I), (II), (III) and (IV) are 2-dimensional real Lie triple algebras, the zero algebra and 2-dimensional Lie triple systems are contained in the type (I). A comprehensive classification of 2-dimensional complex Lie triple systems is given by Yamaguti K. [11] (indeed, the type I above is just the Lemma 5.1 of [11] when the base field is the one of real numbers); see also Jacobson N. [4]. Note that the types (II), (IV) are non-trivial real Lie triple algebras. The algebras of type (V) constitute nontrivial 2-dimensional real Bol algebras (see Corollary 2 below).

**Corollary 1.** There exist nontrivial 2-dimensional real h.t.a. Moreover, any such an algebra is isomorphic to an algebra of type (VI), (VII) or (VIII).

At this point we note that the example of a 2-dimensional real h.t.a. that we gave in [3] is isomorphic to the algebra of type (VI) given by \(u \ast v = dv, u \cdot v = u, \langle w; u, v \rangle = 0, \langle v; u, v \rangle = -u, \ (d \neq 0)\).

The subject of this paper is originally motivated by the need of showing concrete nontrivial h.t.a. Besides, an affine connection space locally permitting a structure of h.t.a. of vector fields is already described in [2] and, conversely, the structure equations of such an affine connection space give rise to a h.t.a. structure on the tangent space at a given point of the manifold. In relation with this, we consider here an example of such an affine connection space with a local loop structure ([10]) with the sole condition that is given a skew-symmetric bilinear function on the space of certain vector fields.

Let \((U, \circ, e)\) be a smooth local loop so that \(U\) is a sufficiently small neighborhood of the fixed point \(e\) of a real \(n\)-dimensional manifold \(M\). We may consider on \(U\) the so-called right fundamental vector fields \(\{X_{\sigma}\}\) of the loop \((U, \circ, e)\) (see, e.g., [9] and references therein), \([X_{\sigma}(x)]^r = X^r_{\sigma}(x), x \in U\). Since \(X_{\sigma}^r(e) = \delta^r_{\sigma}\) and \(e\) is a two-sided identity of \((U, \circ, e)\), it follows that \(X_1, ..., X_n\) define a basis of vector fields linearly independent at each point of \(U\) and thus \(U\) is parallelizable. The Lie bracket of two basis vector fields \(X_{\alpha}, X_{\beta}\) is \([X_{\alpha}, X_{\beta}](x) = C^r_{\alpha\beta}(x)X_r(x)\) (observe that, in contrast of the case of left-invariant vector fields of a Lie group, the \(C^r_{\alpha\beta}\) are functions of point [7, 9]). Now define on \(U\) the \((\cdot)\)-connection \(\nabla_Z Y = 0\) obtained from the parallelization, for any vector fields \(Y, Z\) on \(U\). Assume that on the
space of all right fundamental vector fields on $U$ is given a skew-symmetric bilinear function $a(Y, Z)$. The torsion $T$ of the connection defined above has the expression $T(Y, Z) = -[Y, Z]$. The vector field $[Y, Z] - a(Y, Z)$ is defined on $U$ and so is the vector field $[W, [Y, Z] - a(Y, Z)]$, where $W, Y, Z$ are right fundamental vector fields on $U$. Therefore, with respect to the basis $\{X_1, ..., X_n\}$, we have the representation

\[ (*) \quad [X_i, [X_j, X_k]] - a(X_j, X_k) = r^i_{j,k} X_i, \]

which means that a structure of a h.t.a. of vector fields is locally defined (this is the original definition of a hyporeductive algebra of vector fields [7, 8, 9]). The relation $(*)$ may be written as

\[ (**) \quad (\nabla_i T^a_{jk} - T^i_{ls} (T^s_{jk} + a^s_{jk})) (x) = -r^i_{j,k}(x) \]

for any $x \in U$, where the skew-symmetric tensor $(a^s_{jk})$ is defined by $a(X_j, X_k) = a^s_{jk} X_s$, $(T^s_{jk})$ is the torsion tensor of the connection $\nabla$ and $\nabla_i T^i_{jk}$ denotes the covariant derivative of the function $T^i_{jk}$ by the vector field $X_i$. Since $\{X_1, ..., X_n\}$ is a parallelization, the $r^i_{j,k}$ are constants and the relation $(**)$ means that $\nabla_m (\nabla_i T^i_{jk} - T^i_{ls} (T^s_{jk} + a^s_{jk})) = 0$ at each point of $U$. The structure equations of $(U, \nabla)$ in terms of the basis $\{X_1, ..., X_n\}$ is then

\[ d\omega^i = \frac{1}{2} T^i_{jk} \omega^j \wedge \omega^k, \]

\[ dT^i_{jk} = \nabla_i T^i_{jk} \omega^j. \]

The integrability conditions for these equations (at the point $e$) are precisely the defining identities, written in terms of structure constants, of an abstract h.t.a. and so the tangent space $T_e M$ is provided with a h.t.a. structure (see [2] for the general case of an affine connection space related with a smooth local hyporeductive loop).

Suppose now that $\dim M = 2$ and choose the basis vector fields $X_1, X_2$ such that $[X_1, X_2](e) = 2X_1(e) + X_2(e)$, $(X_1 T^1_{12})(e) = 1$, $(X_1 T^2_{12})(e) = -1$, $(X_2 T^1_{12})(e) = 1$, $(X_2 T^2_{12})(e) = 0$. Moreover, choose the skew-symmetric function $a(Y, Z)$ such that $a(X_1, X_2)(e) = X_1(e) + X_2(e)$. Then, as indicated in the beginning of this section, we may define on $T_e M$ two binary operations $\vec{X}_1 \cdot \vec{X}_2 = \vec{X}_1 + \vec{X}_2$, $\vec{X}_1 \ast \vec{X}_2 = \vec{X}_1$ and, using $(**)$, a ternary operation $\langle \vec{X}_1; \vec{X}_1, \vec{X}_2 \rangle = -\vec{X}_1 + \vec{X}_2$, $\langle \vec{X}_2; \vec{X}_1, \vec{X}_2 \rangle = \vec{X}_1 - \vec{X}_2$, where $\vec{X}_1 := X_1(e)$ and $\vec{X}_2 := X_2(e)$. It is easy to see that the space $T_e M$ along with these operations constitutes a h.t.a. of type VII.

According to the remarks above we have also the following

**Corollary 2.** Any 2-dimensional real Lie triple algebra is isomorphic to one of the algebras of the following types:

$(T1)$ $u \cdot v = 0$, $\langle u; u, v \rangle = \alpha u + \beta v$, $\langle v; u, v \rangle = \gamma u - \alpha v,$
identities (2)-(13) of abstract h.t.a. have the following form:

\[
\begin{align*}
(B17) \quad & u(B16)u(B18)u(B19)u(B15)u(B14)u(B12)u(B13)u(B10)u(B7)u(T3)u(T2)u(a)
\end{align*}
\]

where \( u(B15)u(B14)u(B12)u(B13)u(B10)u(B7)u(T3)u(T2)u(a) = 0 \).

Any 2-dimensional real Bol algebra is isomorphic to one of the algebras of the following types:

(B1) \( u \ast v = 0, \langle u; u, v \rangle = \alpha u + \beta v, \langle v; u, v \rangle = \gamma u - \alpha v, \)

(B2) \( u \ast v = cu + dv, \langle u; u, v \rangle = eu + f v, \langle v; u, v \rangle = ku - ev, \)

(B3) \( u \ast v = cu + dv, \langle u; u, v \rangle = eu + f v, \langle v; u, v \rangle = -ev, \)

(B4) \( u \ast v = cu + dv, \langle u; u, v \rangle = eu, \langle v; u, v \rangle = ku - ev, \)

(B5) \( u \ast v = cu + dv, \langle u; u, v \rangle = eu, \langle v; u, v \rangle = -ev, \)

(B6) \( u \ast v = cu + dv, \langle u; u, v \rangle = f v, \langle v; u, v \rangle = ku, \)

(B7) \( u \ast v = cu + dv, \langle u; u, v \rangle = f v, \langle v; u, v \rangle = 0, \)

(B8) \( u \ast v = cu + dv, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = 0, \)

(B9) \( u \ast v = cu, \langle u; u, v \rangle = eu + f v, \langle v; u, v \rangle = ku - ev, \)

(B10) \( u \ast v = cu, \langle u; u, v \rangle = eu + f v, \langle v; u, v \rangle = -ev, \)

(B11) \( u \ast v = cu, \langle u; u, v \rangle = eu, \langle v; u, v \rangle = ku - ev, \)

(B12) \( u \ast v = cu, \langle u; u, v \rangle = eu, \langle v; u, v \rangle = -ev, \)

(B13) \( u \ast v = cu, \langle u; u, v \rangle = f v, \langle v; u, v \rangle = ku, \)

(B14) \( u \ast v = cu, \langle u; u, v \rangle = f v, \langle v; u, v \rangle = 0, \)

(B15) \( u \ast v = cu, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = ku, \)

(B16) \( u \ast v = cu, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = 0, \)

(B17) \( u \ast v = dv, \langle u; u, v \rangle = eu + f v, \langle v; u, v \rangle = -ev, \)

(B18) \( u \ast v = dv, \langle u; u, v \rangle = eu, \langle v; u, v \rangle = ku - ev, \)

(B19) \( u \ast v = dv, \langle u; u, v \rangle = eu, \langle v; u, v \rangle = -ev, \)

where \( c \neq 0, d \neq 0, e \neq 0, f \neq 0, k \neq 0. \)

\( \square \)

The types (B2)-(B19) constitute just the developed form of the type (V).

3. Proof of the theorem. First we shall prove the following

**Lemma.** If \( \{x_1, x_2\} \) is a basis of a 2-dimensional real h.t.a. \( V \), then the identities (2)-(13) of abstract h.t.a. have the following form:

\[
\begin{align*}
\text{J}(x_1, x_2) = & \quad -x_1 \cdot x_2; x_1, x_2 \\
& + x_1 \cdot (x_2; x_1, x_2) - x_2 \cdot (x_1; x_1, x_2) = 0, \quad \text{(14)} \\
\end{align*}
\]

\[
\begin{align*}
x_i \cdot \text{J}(x_1, x_2) = & \quad -x_i; x_1, (x_2; x_1, x_2) \\
& + (x_i; x_2, (x_1; x_1, x_2)) = 0, \quad \text{(15)} \\
\end{align*}
\]

\[
x_i \ast \text{J}(x_1, x_2) = 0, \quad \text{(16)}
\]

8
\[
\langle x_j; x_i, J(x_1, x_2) \rangle = 0, \quad (17)
\]
\[
\langle x_1 \cdot x_2; x_1, x_2 \rangle - x_1 \cdot \langle x_2; x_1, x_2 \rangle + x_2 \cdot \langle x_1; x_1, x_2 \rangle = 0, \quad (18)
\]
\[
J(x_1, x_2) = 0, \quad (19)
\]

where \( J(x_1, x_2) = x_1 \ast \langle x_2; x_1, x_2 \rangle - x_2 \ast \langle x_1; x_1, x_2 \rangle \) and \( i, j = 1, 2 \).

**Proof.** With respect to the basis \( \{x_1, x_2\} \), (2), (3) and (4) are clearly satisfied trivially. Next the left-hand side of (5) now reads \( x_1 \cdot \langle x_j; x_1, x_2 \rangle \)
\[-x_j \cdot \langle x_i; x_1, x_2 \rangle + \langle x_j \cdot x_i; x_1, x_2 \rangle \) while the right-hand side reads
\[\langle x_1 \ast x_2; x_j; x_i \rangle - \langle x_j \ast x_1; x_1, x_2 \rangle + x_j \ast \langle x_i; x_1, x_2 \rangle - \langle x_j; x_1, x_2 \rangle + (x_1 \ast x_2) \ast (x_j \ast x_i) + (x_1 \ast x_2) \cdot (x_j \ast x_i), \) with \( i, j = 1, 2 \).

Furthermore, because of the skew-symmetry of operations \( \ast, \cdot, \) one observes that the identity (5) gets the form
\[x_1 \ast \langle x_2; x_1, x_2 \rangle - x_2 \ast \langle x_1; x_1, x_2 \rangle = \langle x_1 \cdot x_2; x_1, x_2 \rangle - x_1 \cdot \langle x_2; x_1, x_2 \rangle + x_2 \cdot \langle x_1; x_1, x_2 \rangle, \) so we obtain (14).

In view of (14), the identities (7) and (8) are straightforwardly transformed into (16) and (17) respectively.

Finally, and again with (14) in mind, we work the identity (6) as follows: we replace \( \xi, \eta, \zeta, \kappa, \chi \) by \( x_1, x_2, x_3, x_j, x_i \) respectively where \( i, j, k = 1, 2 \) and then by (14), we see that (6) gets the form
\[x_1 \cdot \langle x_1 \ast x_2; x_j, x_i \rangle - x_2 \ast \langle x_1; x_1, x_2 \rangle + \langle x_i; x_2, x_1; x_2 \rangle \]
\[-\langle x_j; x_1, x_2 \rangle = 0 \) that is, we get (15). The equation (10) implies (19) and hence (18), in view of (14). The equalities (11)-(13) hold trivially in view of (19) and (15).

One observes that (18) and (19) are actually equivalent and accordingly the system (14)-(19) takes a simpler form (see the theorem’s proof below).

We keep the system (14)-(19) as above in order to follow the step by step transformation of the system (2)-(13) in the 2-dimensional case. We now turn to the proof of the theorem.

**Proof of the theorem.**

Let \( (V, \cdot, \langle \cdot, \cdot \rangle) \) be a 2-dimensional real h.t.a. with basis \( \{u, v\} \). Put
\[u \cdot v = au + bv, \ u \ast v = cu + dv, \ \langle u; u, v \rangle = eu + fv, \ \langle v; u, v \rangle = ku + lv.\]

Then, by the lemma, the identities (2)-(13) reduce to (14)-(19) and a careful reading of these identities reveals that the expression \( N = \langle u \cdot v; u, v \rangle \)
\[+v \cdot \langle u; u, v \rangle - u \cdot \langle v; u, v \rangle \) can be conclusive for the study of h.t.a. (at least in the 2-dimensional case). Therefore we shall discuss the case \( N = 0 \) (see(18)).

Thus \( 0 = N = \langle u \cdot v; u, v \rangle + v \cdot \langle u; u, v \rangle - u \cdot \langle v; u, v \rangle = \)

9
\[ \langle au + bv; u, v \rangle + v \cdot (eu + fv) - u \cdot (ku + lv) = (bk - al)u + (af - be)v \text{ implies} \]
\[ bk - al = 0, \]
\[ af - be = 0. \]

Discussing the solutions of the system (20), we see that the following essential situations occur (any other situation is either one of those enumerated below or is included in some of them):
(3.1) \(a \neq 0, b \neq 0, e \neq 0, f \neq 0, k \neq 0, l \neq 0,\)
(3.2) \(a \neq 0, b \neq 0, e \neq 0, f \neq 0, k = 0, l = 0,\)
(3.3) \(a \neq 0, b \neq 0, e = 0, f = 0, k \neq 0, l \neq 0,\)
(3.4) \(a \neq 0, b \neq 0, e = 0, f = 0, k = 0, l = 0,\)
(3.5) \(a \neq 0, b = 0, e \text{ any}, f = 0, k = 0, l = 0,\)
(3.6) \(a = 0, b \neq 0, e = 0, f \text{ any}, k \neq 0, l \text{ any},\)
(3.7) \(a = 0, b = 0, e \text{ any}, f \text{ any}, k \text{ any}, l \text{ any}.\)

Now each of the cases (3.1)-(3.7) must be discussed in connection with the identities (14)-(19). We observe that, with the condition \(N = 0\) (i.e. (18)) only (14) and (15) are of interest here.

The identity (14) implies \(u \ast \langle v; u, v \rangle - v \ast \langle u; u, v \rangle = 0\) which means that
\[ (e + l)u \ast v = 0. \]  

The equation (21) yields the following cases:
(3.8) \(u \ast v = 0\) and \(l \neq -e,\)
(3.9) \(u \ast v = 0\) and \(l = -e,\)
(3.10) \(u \ast v = cu + dv ((c, d) \neq (0,0))\) and \(l = -e.\)

Then considering each of the cases (3.1)-(3.7) in connection with the conditions (3.8)-(3.10), we are led to the following types of algebras:

(A1) \(u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku + lv,\)
\((a \neq 0, b \neq 0, e \neq 0, f \neq 0, k \neq 0, l \neq 0, e a f - be = 0 = bk - al),\)

(A2) \(u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku - ev,\)
\((a \neq 0, b \neq 0, e \neq 0, f \neq 0, k \neq 0, a f - be = 0 = bk + ae),\)

(A3) \(u \ast v = cu + dv, u \cdot v = au + bv, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = ku - ev,\)
\((a \neq 0, b \neq 0, (c, d) \neq (0,0), e \neq 0, f \neq 0, k \neq 0, a f - be = 0 = bk + ae),\)

(A4) \(u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = eu + fv, \langle v; u, v \rangle = 0,\)
\((a \neq 0, b \neq 0, e \neq 0, f \neq 0, k \neq 0, a f - be = 0),\)

(A5) \(u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = ku + lv,\)
\((a \neq 0, b \neq 0, k \neq 0, l \neq 0, bk - al = 0),\)

(A6) \(u \ast v = 0, u \cdot v = au + bv, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = 0,\)
\((a \neq 0, b \neq 0),\)

(A7) \(u \ast v = cu + dv, u \cdot v = au + bv, \langle u; u, v \rangle = 0, \langle v; u, v \rangle = 0,\)
\((a \neq 0, b \neq 0),\)
(a \neq 0, b \neq 0, (c,d) \neq (0,0)),
(A8) \ u \cdot v = cu + dv, \langle u;u,v \rangle = 0, \langle v;u,v \rangle = 0,
(A9) \ u \cdot v = au, \langle u;u,v \rangle = 0, \langle v;u,v \rangle = ku,
(A10) \ u \cdot v = au, \langle u;u,v \rangle = eu, \langle v;u,v \rangle = ku,
(A11) \ u \cdot v = cu + dv, \langle u;u,v \rangle = f v, \langle v;u,v \rangle = 0,
(A12) \ u \cdot v = bv, \langle u;u,v \rangle = f v, \langle v;u,v \rangle = 0,
(A13) \ u \cdot v = bv, \langle u;u,v \rangle = f v, \langle v;u,v \rangle = lv,
(A14) \ u \cdot v = cu + dv, \langle u;u,v \rangle = ku - ev,
(A15) \ u \cdot v = 0, \langle u;u,v \rangle = ku - ev,
(A16) \ u \cdot v = 0, \langle u;u,v \rangle = ku + lv,

Furthermore, the identity (15) implies \langle x;\langle u;u,v \rangle,v \rangle + \langle x;u,\langle v;u,v \rangle \rangle = 0 \text{ with } x = u \text{ or } v, \text{ that is,}

\begin{equation}
(e + l)\langle x; u, v \rangle = 0,
\end{equation}

\( x = u \) or \( v \). The equation (22) gives the following cases:

(3.11) \( l = -e \) and \( \langle x; u, v \rangle \neq 0, x = u \) or \( v \),
(3.12) \( l = -e \) and \( \langle u;u,v \rangle \neq 0, \langle v;u,v \rangle = 0 \),
(3.13) \( l = -e \) and \( \langle u;u,v \rangle = 0, \langle v;u,v \rangle \neq 0 \),
(3.14) \( l = -e \) and \( \langle x; u, v \rangle = 0, x = u \) or \( v \),
(3.15) \( l \neq -e \) and \( \langle x; u, v \rangle = 0, x = u \) or \( v \).

Therefore, in view of constraints (3.11)-(3.15), the algebras of types (A1),
(A4), (A5), (A10), (A13), and (A16) must be cancelled out. Now, observing
that an algebra of type (A8) is isomorphic to the one of type (A11) and
an algebra of type (A9) is isomorphic to the one of type (A12), we are left
with the algebras of types (A2), (A3), (A6), (A7), (A8), (A9), (A14), (A15).
These are precisely the ones enumerated in our classification theorem.

\textbf{Acknowledgement.} The author wishes to thank the referees for their
comments and suggestions that help to improve the initial version of the
present paper. Thank also goes to Petersson H. P. for making available his
relevant article.
