(Received 10 December 2006; revised manuscript received 7 May 2007; published 30 August 2007)

This is a theoretical study of the reversal of a localized quantum spin induced by sequential injection of spins for a spin quantum dot that has a quantum spin. The system consists of “electrode/quantum well (QW)/dot/QW/electrode” junctions, in which the left QW has an energy level of conduction electrons with only up-spin. We consider a situation in which up-spin electrons are sequentially injected from the left electrode into the dot through the QW and an exchange interaction acts between the electrons and the localized spin. To describe the sequentially injected electrons, we propose a simple method based on approximate solutions from the time-dependent Schrödinger equation. Using this method, it is shown that the spin reversal occurs when the right QW has energy levels of conduction electrons with only down-spin. In particular, the expression of the reversal time of a localized spin is derived, and the upper and lower limits of the time are clearly expressed. This expression is expected to be useful for a rough estimation of the minimum relaxation time of the localized spin to achieve the reversal. We also obtain analytic expressions for the expectation value of the localized spin and the electrical current as a function of time. In addition, we found that a system with the nonmagnetic right QW exhibits spin reversal or nonreversal depending on the exchange interaction.

I. INTRODUCTION

Magnetization reversal by spin injection (MRSI), in which the magnetization of a ferromagnet (FM) is reversed by injecting a spin-polarized current into the FM, is one of the most interesting topics in the field of spin-dependent transport and spin electronics for the following reasons: First, the reversal is induced by the current and not by the conventional method, such as the application of magnetic fields. Second, such a phenomenon is expected to have potential applications for the writing of data in the magnetic memory.

Originally, the MRSI was theoretically predicted by Slonczewski and Berger. Their systems are FM/nonmagnetic layer/FM junctions, in which the current flows perpendicularly to the plane. Here, the magnetization of the FM is described by classical spins, and an exchange interaction acts between the magnetization and the electron spin. When the magnetization of one FM is free to change its direction and that of the other FM is pinned, the magnetization of the former can be changed to become either parallel or antiparallel to that of the latter depending on the direction of the current. In addition, some theoretical studies, in which the magnetization of the FM is described by the classical spins, have been reported since then.

Quite recently, the MRSI has been experimentally observed in FM/nonmagnetic layer/FM junctions and pillars. The experimental results have often been analyzed by using the theoretical model based on classical spins. The magnetization of the FM appears to be fairly well described by the classical spins.

On the other hand, we expect that magnetic materials will undergo transformation from classical spin systems into quantum spin ones along with miniaturization toward high-density integration devices in the future. For example, such quantum spin systems are Mn12 magnetic molecules, A Mn12 molecule possesses an effective spin of $S = 10$ due to an antiferromagnetic interaction between the eight Mn$^{3+}$ ions ($S = 2$) and the four Mn$^{2+}$ ions, and it has a uniaxial anisotropy energy, which is an anisotropy constant with the magnitude of 0.7 K. The anisotropy energy shows a bistable potential between $S_z = 10$ and $-10$ states. Regarding a characteristic phenomenon due to this potential, the quantum tunneling of magnetization has been experimentally observed under a magnetic field. This phenomenon has been analyzed by using the quantum spin model with anisotropy energy.

If the spin-polarized current can be injected into such quantum spin systems, the conventional magnetization reversal may be replaced by the localized quantum spin reversal. In the present condition, however, very few theoretical studies for quantum spin reversal have been reported. Our primary focus is on what models bring about the quantum spin reversal and the length of the reversal time of the localized spin. The latter is important for the purpose of roughly estimating the minimum relaxation time of the localized spin to achieve the reversal.

In this paper, we examined the quantum spin reversal induced by the sequential injection of spins for a spin quantum dot having a quantum spin. The system consists of “electrode/quantum well (QW)/dot/QW/electrode” junctions, where the left QW (L) has an energy level of conduction electrons with only up-spin. We considered a situation in which up-spin electrons were sequentially injected from the left electrode into the dot through the L. To describe the sequentially injected electrons, we first proposed a simple method based on the time-dependent Schrödinger equation. Using this method, we obtained an expression of the reversal...
FIG. 1. Schematic illustration of “electrode/L/spin quantum dot/R/electrode” junctions. L has an energy level of conduction electrons with up-spin, while R has N_l energy levels of conduction electrons with up-spin and N_r with down-spin. The shaded area in the electrodes represents the region occupied by electrons. The bias voltage (the gate voltage) is applied to the electrodes (L and R). In addition, the equivalent circuit is shown in Fig. 10.

The time of the localized spin when the right QW (R) had energy levels of conduction electrons with only down-spin. Furthermore, analytic expressions for the expectation value of the localized spin and the electrical current were obtained as a function of time. We also found that the spin reversal occurred for the case of the specific exchange integral even when R was nonmagnetic.

The present paper is organized as follows. In Sec. II, we present the model of the spin quantum dot and the assumptions for the sequential injection of spins. In Sec. III, we provide a theoretical formulation; the wave function, the electrical current, and the expectation value of localized spin are derived. In Sec. IV A, this theory is applied to the case of spin-polarized R, while Sec. IV B presents the application to the case of nonmagnetic R. In Sec. V, we make a proposal for a model with reversible switching and discuss the experimental aspects. Section VI presents the conclusion, and the Appendix presents information about the bias and gate voltages.

II. MODEL

A. Spin quantum dot

In Fig. 1, we show a system consisting of “electrode/L/spin quantum dot/R/electrode” junctions, where the electrons flow from the left electrode to the right one under the bias voltage between the electrodes, and furthermore, the gate voltage is applied to L and R (see Sec. VII). Here, the dot region behaves as a tunnel barrier, and tunnel barriers are set between the left electrode and L, and between R and the right electrode. L and R form the QW; that is, L has an energy level of conduction electrons with up-spin and N_l with down-spin. Those levels in R are introduced to accept electrons exhibiting the elastic and inelastic transport [see Sec. II B (iv)]. The left electrode (right electrode) is a nonmagnet or ferromagnet, in which the direction of the spin polarization is the same as that of L (R). The shaded area in the electrodes represents the region occupied by electrons. In the dot, the quantum spin S=(S_x,S_y,S_z) with S=1 is localized and is weakly coupled to L and R. The localized spin has a uniaxial anisotropy energy showing a bistable potential, −|D|S_z^2. The energy levels of the localized spin can be characterized by S_z. It is also assumed that the magnetic easy axis of the localized spin is collinear to that of the electron spins at L and R. In addition, the magnetic couplings between the localized spin and the QWs are negligibly small.

B. Assumptions

On the condition that the initial state of the localized spin is S_z=−S, up-spin electrons are sequentially injected from the left electrode into the dot. To describe the sequentially injected electrons, we have the following assumptions:

(i) This system exhibits single electron tunneling (SET), in which the up-spin electrons are injected from the left electrode into the dot one by one under specific bias and gate voltages (see Sec. VII). Concretely speaking, when the probability density of the electron becomes 0 at L and 1 at R, the electron moves into the right electrode and the subsequent electron is injected into L.

The situation in which the mth electron runs in the dot is named as the mth process. When the time period of the mth process is represented by ΔV^{(m)}; the end time of the mth process, t_m, is defined by t_m=Σ_{m'=1}^{m}ΔV^{(m')}. Here, t_0=0 is the initial time.

(ii) When the transport of the electron is caused by interaction V between L and R, V acts while each electron runs in the L-dot-R system. On the other hand, V is switched off when the electron is outside of this system. The interaction for the mth injected electron at time T, V^{(m)}(T), is written as

\[
V^{(m)}(T) = \begin{cases} 
V & \text{for } t_{m-1} < T \leq t_m \\
0 & \text{for } T \leq t_{m-1}, T > t_m
\end{cases}
\]

(1)

(see Fig. 2). As found from V^{(m)}(T), each process is independent.

The interaction V is given by a transmission term including the exchange interaction between the electron and the localized spin. This term is obtained within the second-order perturbation theory based on the weak couplings between the dot and the QWs. The L, R, and dot parts are described by an unperturbed Hamiltonian, in which the on-
site Coulomb energy is considered in the dot. The couplings between the dot and the QWs are perturbation terms. The resultant $V$ is now expanded to a more general system, namely, the anisotropic exchange interaction.\textsuperscript{23} The expression is written as

$$V = V_0 \sum_{n=1}^{N_1} (c_{Rn}^c c_{L} + c_{L}^c c_{Rn}) + J_\perp \sum_{n=4}^{N_1} (c_{Rn}^c c_{L}^c S_n + c_{L}^c c_{Rn} S_n) + J_\parallel \sum_{n=1}^{N_1} \langle c_{Rn}^c c_{L}^c S_n + c_{L}^c c_{Rn} S_n \rangle .$$

Here, $c_j$ ($c_j^c$) is the annihilation (creation) operator of an electron of $j=L$ or $R_{na}$, where the suffix $L$ ($R_{na}$) denotes the level of conduction electrons with up-spin of $L$ (the $n$th level of conduction electrons with a $\sigma$ spin of $R$). Furthermore, $V_0$ denotes the coefficient for direct tunneling, while $J_\perp$ ($J_\parallel$) is the coefficient for tunneling with a transverse (longitudinal) exchange interaction between the electron and the localized spin. From now on, we call $J_\perp$ ($J_\parallel$) the exchange integral.

(iii) The localized spin canted by the electron is not rapidly relaxed and interacts with the subsequently injected electron.

(iv) The system has the relation of $|E_L - E_{R_{na}}| \leq |V|$, where $E_L$ ($E_{R_{na}}$) denotes the energy level of conduction electrons with the up-spin of $L$ (the $n$th energy level of conduction electrons with the $\sigma$ spin of $R$). The energy levels contain the potential due to the gate voltage. Here, the central region in $E_{R_{na}}$ is located in the vicinity of $E_L$. The bandwidth in $E_{R_{na}}$ is about $2|D|(2S-1)$, with $|D| = 1.5$ $D$ ($2S-1$), where $|D| = 2S-1$ corresponds to the maximum energy that the conduction electron absorbs from the localized spin or gives to the spin for the case of the energy conservation. Consequently, $|E_L - E_{R_{na}}| \leq |V|$ corresponds to $|D| \leq |V|$. Note that the assumption greatly simplifies the calculation (see Sec. III A).

As mentioned in Sec. III A (see also Ref. 24), the above assumption leads to the relation of $\Delta m^0 \ll h/|E_L - E_{R_{na}}|$, where $h$ is the Planck constant $h$ divided by $2\pi$. On the basis of the relation, we investigate the motion of the electron within the $L$-dot-$R$ system using the wave function obtained from the time-dependent Schrödinger equation. In contrast, Fermi’s golden rule, which is a method to investigate the transport property, is applicable to the case of $\Delta m \gg h/|E_L - E_{R_{na}}|$. We also note that in a short time period such as $\Delta m^0$, the total energy becomes uncertain according to the uncertainty relation between time and energy, although the energy can be certainly conserved after enough time has passed. The electrons then exhibit the elastic and inelastic transport. Such electrons are accepted by some energy levels in $R$.

### III. THEORETICAL FORMULATION

#### A. Wave function

In order to obtain the wave function of the $m$th process, $|\Phi_{m}^{(m)}(t)\rangle$ with $t = t_{m-1}$ and $0 < t < \Delta m^0$, we solve the time-dependent Schrödinger equation,

$$i\hbar \frac{\partial}{\partial t} |\Phi_{m}^{(m)}(t)\rangle = \mathcal{H}^{(m)}(t) |\Phi_{m}^{(m)}(t)\rangle ,$$

with

$$\mathcal{H}^{(m)}(t) = \mathcal{H}_0 + V^{(m)}(t) ,$$

where $\mathcal{H}_0$ is the Hamiltonian for the electronic states of $L$, $R$, and the localized spin state. The wave function $|\Phi_{m}^{(m)}(t)\rangle$ for $0 < t \leq \Delta m^0$ is expressed as

$$|\Phi_{m}^{(m)}(t)\rangle = \sum_{j=\pm} \sum_{j=\pm} \sum_{j=\pm} a_{j,m}^{(m)}(t) e^{-iE_j t / \hbar} |j, S_j\rangle ,$$

with

$$\mathcal{H}_0 |j, S_j\rangle = E_{j,S_j} |j, S_j\rangle ,$$

for $j=L$ or $R_{na}$, and $E_{L,S_L} = E_L - |D| S_L^2$ and $E_{R_{na},S_L} = E_{R_{na}} - |D| S_L^2$. The state $|L_{(R_{na})}, S_j\rangle$ means that the electron exists at the level of $L$ (at the $n$th level of the $\sigma$ spin of $R$) and the localized spin has $S_j$. The equation to determine the coefficient $a_{j,m}^{(m)}(t)$ for $0 < t \leq \Delta m^0$ is given by

$$a_{j,m}^{(m)}(t) = \frac{1}{\mathcal{N}} \sum_{k,s} \sum_{s} \langle j, S_j | V_{k,s} | k, S_k \rangle a_{k,m}^{(m)}(t) e^{-iE_{j,s} t / \hbar} ,$$

We obtain equations for $a_{L,S_L}^{(m)}(t)$, $a_{R_{na},S_L}^{(m)}(t)$, and $a_{R_{na},S_L}^{(m)}(t)$ using $\langle R_{na}, S_L, S_L+1 | V_{L,S_L} | L, S_L \rangle = F_{S_L}^{(m)}$ and $\langle (R_{na}, S_L, S_L+1 | V_{L,S_L} | L, S_L \rangle = (L, S_L) | V_{R_{na}, S_L} \rangle = V_{0} + J_{S_L} = G_{S_L}$. Their equations are summarized as follows:

$$a_{L,S_L}^{(m)}(t) = \frac{F_{S_L}}{h^2} N_{L} a_{L,S_L}^{(m)}(t) - \frac{G_{S_L}}{h^2} N_{L} a_{L,S_L}^{(m)}(t) + f_{S_L}^{(m)}(t) + g_{S_L}^{(m)}(t) ,$$

with

$$f_{S_L}^{(m)}(t) = \frac{F_{S_L}}{h^2} \sum_{n=1}^{N_1} \Delta_{R_{na},\pm} a_{R_{na},S_L+1}^{(m)}(t) e^{i\Delta_{R_{na},S_L+1} t / \hbar} ,$$

$$g_{S_L}^{(m)}(t) = \frac{G_{S_L}}{h^2} \sum_{n=1}^{N_1} \Delta_{R_{na},\pm} a_{R_{na},S_L-1}^{(m)}(t) e^{i\Delta_{R_{na},S_L-1} t / \hbar} ,$$

$$\Delta_{R_{na}, \pm} = E_{L,S_L} - E_{R_{na},S_L+1} \pm 1 ,$$

and

$$\Delta_{R_{na}, \pm} = E_{L,S_L} - E_{R_{na},S_L-1} \pm 1 ,$$

where the sum $\sum_{n=1}^{N_1} (\sum_{n=1}^{N_1})$ excludes $n_\downarrow$ \((n_\uparrow)\), giving $\Delta_{R_{na},\pm} = 0$ ($\Delta_{R_{na},\pm} = 0$).

According to $|E_L - E_{R_{na}}| \ll |J_\downarrow|$, $|J_\downarrow|$, and $|V_0|$ of Sec. II B (iv), the present system has the relations $|\Delta_{R_{na},\pm}/F_{S_L}|$
\[ \| a_{R_{n_{1}}}^{(m)} \| = 0 \] obtained under the condition that the initial state of the localized spin is set to be \( S_{z} = -S \). The use of the coefficients, however, is considered to be valid for the study of the qualitative properties of the present system, with \( | E_{L_{1}} - E_{R_{n_{1}}} | \ll | J_{[1]} |, | J_{[2]} |, \) and \( | V_{0} | \).

We substitute Eqs. (14)–(16) into Eq. (5). The wave function \( | \Phi^{(m)}(t) \rangle \) for \( 0 < t \leq \Delta t^{(m)} \) is finally written as

\[
| \Phi^{(m)}(t) \rangle = \sum_{S_{z} = -S}^{S} A_{L_{2}}^{(m)}(t) e^{-i\hat{E}_{L_{2}} S_{z} t} | L_{2}, S_{z} \rangle + \sum_{n=1}^{N_{L_{1}}} \sum_{S_{z} = -S}^{S} A_{R_{n_{1}} S_{z}}^{(m)}(t) \times (t) e^{-i\hat{E}_{R_{n_{1}}} S_{z} t} | R_{n_{1}}, S_{z} \rangle + \sum_{n=1}^{N_{R_{1}}} \sum_{S_{z} = -S}^{S} A_{R_{n_{1}} S_{z} + 1}^{(m)}(t) \times (t) e^{-i\hat{E}_{R_{n_{1}}} S_{z} + 1} | R_{n_{1}}, S_{z} + 1 \rangle ,
\]

with

\[
A_{L_{2}}^{(m)}(t) = \frac{a_{L_{2}}^{(m)}(t)}{a^{(m)}(t)}, \quad A_{R_{n_{1}} S_{z}}^{(m)}(t) = \frac{a_{R_{n_{1}} S_{z}}^{(m)}(t) e^{-i\hat{E}_{R_{n_{1}} S_{z}} t}}{a^{(m)}(t)},
\]

where \( a^{(m)}(t) \) is the normalization factor,

\[
a^{(m)}(t) = \left[ \sum_{S_{z} = -S}^{S} | a_{L_{2}}^{(m)}(t) \rangle \langle L_{2}, S_{z} | ^{2} + \sum_{n=1}^{N_{L_{1}}} \sum_{S_{z} = -S}^{S} | a_{R_{n_{1}} S_{z}}^{(m)}(t) \rangle \langle R_{n_{1}} S_{z} | ^{2} \right]^{1/2} + \sum_{n=1}^{N_{R_{1}}} \sum_{S_{z} = -S}^{S} | a_{R_{n_{1}} S_{z} + 1}^{(m)}(t) \rangle \langle R_{n_{1}} S_{z} + 1 | ^{2} \right]^{1/2} .
\]

The local probability densities at \( L \) and \( R \) are given by

\[
\langle \phi^{(m)}(t) | L | \phi^{(m)}(t) \rangle = \sum_{S_{z} = -S}^{S} | A_{L_{2}}^{(m)}(t) \rangle \langle L_{2}, S_{z} | ^{2},
\]

\[
\langle \phi^{(m)}(t) | R | \phi^{(m)}(t) \rangle = \sum_{S_{z} = -S}^{S} | A_{R_{n_{1}} S_{z}}^{(m)}(t) \rangle \langle R_{n_{1}} S_{z} | ^{2},
\]

with

\[
S_{z} = \frac{\sqrt{N_{L_{2}} F_{S_{z}}^{2} + N_{R_{1}} G_{S_{z}}^{2}}}{\hbar},
\]

for \( 0 < t \leq \Delta t^{(m)} \). Here, \( a_{L_{2}}^{(m)}(t) \) and \( a_{R_{n_{1}}}^{(m)}(t) \) are obtained by using \( a_{L_{2}}^{(m)}(t) \) and Eqs. (9) and (10), where \( \Delta t_{L_{2}}^{(m)} \) and \( \Delta t_{R_{n_{1}}}^{(m)} \) are taken as \( 0 \) because \( t \) is considered to be at most, several times larger than \( 1/\Omega_{S_{z}} \) in this study.\(^{25}\) and further, \( | \Delta t_{L_{2}}^{(m)} / F_{S_{z}} | \ll 1 \) and \( | \Delta t_{R_{n_{1}}}^{(m)} / G_{S_{z}} | \ll 1 \) are introduced as stated earlier.

In fact, the coefficients of Eqs. (14)–(16) correspond to exact expressions for a system of \( D = 0 \) and \( \Delta t_{L_{2}}^{(m)} = \Delta t_{R_{n_{1}}}^{(m)} = \Delta t^{(m)} \).

B. Number of electrons in \( R \) and in the right electrode

On the basis of Eq. (21), we obtain the number of electrons in \( R \) and in the right electrode for the \( m \)th process, \( n_{r}^{(m)}(t) \). The expression is written as

\[
n_{r}^{(m)}(t) = (m - 1) + N_{L_{1}} \sum_{S_{z} = -S}^{S} | A_{R_{n_{1}}}^{(m)}(t) \rangle \langle R_{n_{1}} S_{z} | \rangle ^{2} + N_{R_{1}} \sum_{S_{z} = -S}^{S} | A_{R_{n_{1}}}^{(m)}(t) \rangle \langle R_{n_{1}} S_{z} + 1 \rangle ^{2},
\]

for \( 0 < t \leq \Delta t^{(m)} \). The first term on the right-hand side represents the number of electrons which have moved
to the right electrode. The second and third terms are \( \langle \Phi^{(m)}(t) | R | \Phi^{(m)}(t) \rangle \) of Eq. (21). Furthermore, \( n_r^{(m)}(t) = \langle \Phi^{(m)}(t) | R | \Phi^{(m)}(t) \rangle \) is regarded as the expectation value of the position of the \( m \)th injected electron when the positions of \( L \) and \( R \) are set to be 0 and 1, respectively.

C. Electrical current

The electrical current of the \( m \)th electron, \( I^{(m)}(t) \), is defined by

\[
I^{(m)}(t) = -e n_s S_d \frac{d}{dt} \langle \Phi^{(m)}(t) | R | \Phi^{(m)}(t) \rangle
\]

\[
= -e n_s S_d \sum_{s=-S}^{S} B^{(m)}(t) \Omega S_s \sin(2 \Omega S_t),
\]

(23)

for \( 0 < t \leq \Delta t^{(m)} \).

D. Expectation value of the localized spin

The expectation value of the localized spin of the \( m \)th process, \( \langle S_t^{(m)}(t) \rangle \), is obtained by using Eq. (18). The expression is given by

\[
\langle S_t^{(m)}(t) \rangle = \langle \Phi^{(m)}(t) | S_t | \Phi^{(m)}(t) \rangle
\]

\[
= \sum_{s=-S}^{S} A_{L_s}^{(m)}(t)^2 + N_s \sum_{s=-S}^{S} A_{R_s}^{(m)}(t)^2
\]

\[
+ N_s \sum_{s=-S}^{S-1} (S + 1) A_{L_s}^{(m)} A_{R_s}^{(m)}(t)^2,
\]

(24)

for \( 0 < t \leq \Delta t^{(m)} \).

IV. APPLICATIONS

A. Spin-polarized \( R \) with only down-spin levels

The spin reversal occurs when \( R \) has energy levels of conduction electrons with only down-spin. In this system, \( V \) is described by only the second term in Eq. (2) because of \( N_0 = 0 \). Furthermore, \( G_{S, R_s}^{(m)}(t) \), and \( A_{R_s}^{(m)}(t) \) are set to be 0.

We obtain \( \langle \Phi^{(m)}(t) \rangle \) for \( 0 < t \leq \Delta t^{(m)} \) using Eqs. (14), (15), and (18), and \( B^{(m)}_{s} = \delta_{m,s+S+1} \), which is Eq. (12) for this system. The expression is written as

\[
\langle \Phi^{(m)}(t) \rangle = \cos(\omega_0 t) e^{-i \delta \Delta t^{(m)} [L, S_t]}
\]

\[
- \sum_{n=1}^{N_s} \frac{i \Omega}{N_s} \sin(\omega_0 t) e^{-i \delta \Delta t^{(m)} [R_n, S_t + 1]}
\]

(25)

with

\[
\omega_0 = \frac{J_{s}^2}{\sqrt{N_s} (S - S_t) (S + S_t + 1)}
\]

(26)

and \( m = S_t + S + 1 \) for \( S_t = -S - 1 \). From Eq. (25), the partial probability density is obtained as follows:

\[
\langle L, S_t | \Phi^{(m)}(t) \rangle^2 = \cos^2(\omega_0 t)
\]

(27)

\[
\sum_{n=1}^{N_s} \langle R_n, S_t + 1 | \Phi^{(m)}(t) \rangle^2 = \sin^2(\omega_0 t)
\]

(28)

with \( m = S_t + S + 1 \) for \( S_t = -S - 1 \). For \( m = S_t + S + 1 \), \( \langle L, S_t | \Phi^{(m)}(t) \rangle^2 \) decreases from 1 to 0, and \( \sum_{n=1}^{N_s} \langle R_n, S_t + 1 | \Phi^{(m)}(t) \rangle^2 \) increases from 0 to 1 with increasing \( t \) (see Fig. 3). This behavior means that the electron transfers from \( L \) to \( R \) with the spin flip from up to down and the localized spin changes from \( S_t \) to \( S_t + 1 \). Since the \( m \)th process is finished at \( t = \pi/2 \omega_0 \), \( \Delta t^{(m)} \) is given by

\[
\Delta t^{(m)} = \frac{\pi}{2 \omega_0} = \frac{h}{4 |J_s| \sqrt{N_s} (S - S_t) (S + S_t + 1)}
\]

(29)

with \( m = S_t + S + 1 \) for \( S_t = -S - 1 \). Here, \( m = S_t + S + 1 \) for \( S_t = -S - 1 \) represents \( m = 1, 2, 3, 4, \ldots, 2S \). The spin reversal is thereby achieved after the \( 2S \)th process, where \( 2S \) also corresponds to the total number of injected electrons.

Using Eq. (29), we can obtain the reversal time of the localized spin, \( t_R \), which is the total time to transform \( S_t \) from \( -S \) to \( S \). When \( \Delta t^{(m)} \), with \( m = S_t + S + 1 \), of Eq. (29) is renamed as \( \Delta t_{s} \), \( t_R \) is simply written as

\[
\Delta t_{s} = \sum_{S_t=-S}^{S_t+S+1} \frac{h}{4 |J_s| \sqrt{N_s} (S - S_t) (S + S_t + 1)}
\]

(30)

Figure 4 shows the \( S \) dependence of \( t_R \) for \( \sqrt{N_s}/h \). At \( S = 1 \), \( t_R \) takes \( h/\sqrt{2} (|J_s|/\sqrt{N_s}) \). On the condition that \( |J_s|/\sqrt{N_s}/h \) is a constant, \( t_R \) monotonically increases with increasing \( S \). This behavior is explained by considering that the spin reversal is caused by injecting \( 2S \) up-spin electrons into the dot. In the classical spin limit of \( S \rightarrow \infty \), \( t_R \) comes close to \( h \pi/(4 |J_s| \sqrt{N_s}) \) which is obtained by replacing \( \sum_{S_t=-S}^{S_t+S+1} \) with

\[
0.544451-5
\]
lim_{S \to \infty} \int_{-S}^{S} dS_z. We, thus, find that the \( t_R \) of systems with \( S \gg 1 \) has the following relation:

\[
\frac{\hbar \sqrt{2}}{4|J_+| |N_{\uparrow}|} \leq t_R < \frac{\hbar \pi}{4|J_+| |N_{\uparrow}|}.
\] (31)

Furthermore, since this \( t_R \) is derived under Sec. II B (iii), we emphasize that the spin reversal is realized when the relaxation time of the localized spin, \( \tau \), satisfies the relation \( \tau > t_R = \frac{2^{3/2}}{S_z} h |N_{\uparrow}|/\sqrt{N_{\uparrow}(S-S_z)(S+S_z+1)} |J_+| \).

As an application, we consider a system with \( S=5 \), \( N_{\uparrow} = 50 \), and \( |J_+| = 0.001 \text{ eV} \). The reversal time \( t_R \) is evaluated to be \( 3.3 \times 10^{-13} \text{ s} \) by using Eq. (30). The relation \( \tau > 3.3 \times 10^{-13} \text{ s} \) is essential for an experimental observation of this spin reversal.

The upper panel of Fig. 5 shows the \( T \) dependence of \( n_r^{(m)}(T-t_{m-1}) \), with \( m=1-10 \). The number of electrons in \( R \) and in the right electrode, \( n_r^{(m)}(T-t_{m-1}) \), increases from 0 to 10 with increasing \( T \) and becomes 10 at \( T=t_{R}=3.3 \times 10^{-13} \text{ s} \). The reversal is eventually achieved by injecting 10 (=2\( S_z \)) electrons into the dot. Furthermore, it is noted that the slope becomes zero at \( t_{R,m} \), with \( m=1-9 \).

The middle panel of Fig. 5 shows the \( T \) dependence of \( I^{(m)}(T-t_{m-1})/(\xi_{m-1}eN_{\sigma}) \). The quantity \( I^{(m)}(T-t_{m-1})/(\xi_{m-1}eN_{\sigma}) \) exhibits a single peak for each process. The peak takes the largest value for the fifth and sixth processes, where the respective initial states have \( S_z=1 \) and 0. This behavior reflects the fact that \( \omega_{S_z} \) achieves its maximum at \( S_z=-1 \) and 0 for \( S=5 \) (see also Eq. (23)).

The lower panel of Fig. 5 shows the \( T \) dependence of \( \langle S_{z}^{(m)}(T-t_{m-1}) \rangle \). The expectation value of the localized spin \( \langle S_{z}^{(m)}(T-t_{m-1}) \rangle \) increases from \(-5 \) to 5 with increasing \( T \) following the same pattern as that of \( n_r^{(m)}(T-t_{m-1}) \). It finally becomes 5 at \( T=t_{R}=3.3 \times 10^{-13} \text{ s} \); that is, the spin reversal is completed at this \( t_{R,m} \).

B. Nonmagnetic \( \mathbf{R} \)

In the case of nonmagnetic \( \mathbf{R} \) with \( N_{\downarrow}=N_{\uparrow} \), this system exhibits spin reversal or nonreversal depending on the exchange integral.

Regarding the spin reversal, all injected electrons can transfer from \( L \) to \( R \); that is, the local probability density at \( L \) becomes zero at a certain time for each process (see Sec. II B

\[
\text{FIG. 4. Spin quantum number } S \text{ dependence of the reversal time of the localized spin, } t_R. \text{ Here, } t_R|_{N_{\uparrow}}/\hbar \text{ takes } \sqrt{2}/4 \text{ at } S=1, \text{ while it comes close to } \pi/4 \text{ in the classical spin limit of } S \to \infty.
\]

\[
\text{FIG. 5. } T \text{ dependence of the number of electrons in } R \text{ and in the right electrode, } n_r^{(m)}(T-t_{m-1}); \text{ electrical current, } I^{(m)}(T-t_{m-1}); \text{ and expectation value of the localized spin, } \langle S_{z}^{(m)}(T-t_{m-1}) \rangle. \text{ Upper panel: } n_r^{(m)}(T-t_{m-1}); \text{ Middle panel: } I^{(m)}(T-t_{m-1}); \text{ Lower panel: } \langle S_{z}^{(m)}(T-t_{m-1}) \rangle.
\]

(i)]. We, therefore, pay attention to the local probability density at \( L \) of the \( m \)th process,

\[
\langle \Phi^{(m)}(t) | \mathcal{L} | \Phi^{(m)}(t) \rangle \propto \sum_{S_{z}\in\{\pm1\}} \mathcal{L}^{(m)}_{S_{z}} \cos^{2}(\Omega_{S_{z}} t),
\]

which is obtained from Eqs. (14) and (20). Equation (32) becomes zero at \( t = \Delta t^{(m)} \), when \( \Delta t^{(m)} \) satisfies the following relation:

\[
\Omega_{S_{z}} \Delta t^{(m)} = \left( \mathcal{L}^{(m)}_{S_{z}} + \frac{1}{2} \right) \pi
\]

for any \( S_{z} \) giving finite \( \mathcal{L}^{(m)}_{S_{z}} \). Here, \( \mathcal{L}^{(m)}_{S_{z}} \) (\( \geq 0 \)) is the counting number.

In the first process with \( \mathcal{L}^{(1)}_{S_{z}} = 1 \), Eq. (32) becomes \( \cos^{2}(\Omega_{S_{z}} t) \), and it certainly takes a zero value at \( t = \Delta t^{(1)} = \pi/2\Omega_{S_{z}} \). In the \( m \)th process with \( m \geq 2 \), \( \mathcal{L}^{(m)}_{S_{z}} \) is finite for any \( S_{z} \). Whether Eq. (33) is satisfied for \( m \geq 2 \) or not depends on the parameter set of the exchange integral.

We first investigate the parameter set satisfying Eq. (33) in order to find the spin reversal. For a system with \( S=2 \) and \( N_{\downarrow}=N_{\uparrow}=20 \), the parameter set is, for example, \( V_{0} = 0.001 \text{ eV}, J_{\uparrow}/V_{0} = 12/31, \text{ and } J_{\downarrow}/V_{0} = 2\sqrt{\Gamma}/13 \). In Table I, we summarize \( b_{S_{z}}^{(m)} \) and \( \Delta t^{(m)} \) for each \( m \). The first process with \( b_{2}^{(1)} = 1 \) has \( \Delta t^{(1)} = \pi/2\Omega_{-2} = 4.78 \times 10^{-13} \text{ s} \), and the \( m \)th process with \( m \geq 2 \) has \( \Delta t^{(m)} = 3\pi/2\Omega_{-2} = 1.43 \times 10^{-12} \text{ s} \).
TABLE I. Initial amplitude of the $m$th process, $b_{S_z, 0}^{(m)}$, counting number of the $m$th process, $n_r^{(m)}$, and time period of the $m$th process, $\Delta t^{(m)}$, for the system of $S=2$, $N_r=N_s=20$, $V_0=0.001$ eV, $J_+/V_0=12/31$, and $J_-/V_0=2\sqrt{11}/31$.

| $m$ | $b_{S_z, 0}^{(m)}$ | $b_{S_z, 1}^{(m)}$ | $b_{S_z, 0}^{(m)}$ | $b_{S_z, 1}^{(m)}$ | $b_{S_z, 2}^{(m)}$ | $b_{S_z, 2}^{(m)}$ | $\Delta t^{(m)}$ |
|-----|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| 1   | 1               | 0               | 0               | 0               | 0               | 0               | $\pi/2\Omega_{-2}$ |
| 2   | 0.47            | 0.88            | 0               | 0               | 0               | 0               | $3\pi/2\Omega_{-2}$ |
| 3   | 0.22            | 0.79            | 0.57            | 0               | 0               | 0               | $3\pi/2\Omega_{-2}$ |
| 4   | 0.10            | 0.64            | 0.72            | 0.26            | 0               | 0               | $3\pi/2\Omega_{-2}$ |
| 5   | $0.50\times 10^{-1}$ | 0.50            | 0.76            | 0.41            | 0.73 $\times 10^{-1}$ | 0               | $3\pi/2\Omega_{-2}$ |
| 6   | $0.38 \times 10^{-9}$ | $0.65 \times 10^{-3}$ | $0.58 \times 10^{-1}$ | 0.44            | 0.90            | 0               | $3\pi/2\Omega_{-2}$ |
| 7   | $0.67 \times 10^{-18}$ | $0.50 \times 10^{-6}$ | $0.26 \times 10^{-2}$ | 0.14            | 0.99            | 0               | $3\pi/2\Omega_{-2}$ |

The upper panel of Fig. 6 and the upper panel of Fig. 7 show the $T$ dependence of $n_r^{(m)}(T-t_{m-1})$ with the above parameter set in the regions of $0 \leq T \leq 8 \times 10^{-11}$ s and $0 \leq T \leq 1 \times 10^{-11}$ s, respectively. Here, $T=8 \times 10^{-11}$ s ($T=1 \times 10^{-11}$ s) corresponds to the time in the 57th (8th) process. The number of electrons in $R$ and in the right electrode, $n_r^{(m)}(T-t_{m-1})$, slightly oscillates in each process and clearly increases with increasing $T$. In the middle panel of Fig. 7, it
is shown that \( I^{(m)}(T-t_{m-1})/(-e_n S_d) \) oscillates between positive and negative values.

The lower panel of Fig. 6 and the lower panel of Fig. 7 show the \( T \) dependence of \( \langle S_{\uparrow}^{(m)}(T-t_{m-1}) \rangle \) in the respective regions of \( T \). The expectation value of the localized spin, \( \langle \hat{S}_{\uparrow}^{(m)}(T-t_{m-1}) \rangle \), has a slight oscillation in each process as well. The spin reversal is almost realized in the vicinity of \( T=8.0 \times 10^{-11} \) s, and it is also confirmed from \( \tilde{b}_{2}^{(m)}=0.99 \) in Table I.

As the spin nonreversal case for \( S=2 \) and \( N_{L}=N_{R}=20 \), we choose, for example, the parameter set of \( V_{0}=0.001 \) eV, \( J_{L}/V_{0}=1 \), and \( J_{R}/V_{0}=2 \). The first process with \( b_{2}^{(1)}=1 \) and \( b_{2}^{(2)}=1 \) becomes \( |\Phi^{(1)}(t)| \Phi^{(2)}(t)|^{2} \approx \cos^{2}(\Omega_{2} t) \) and it takes a zero value at \( t=\pi/2\Omega_{2} \approx 6.4 \times 10^{-14} \) s. In fact, the first injected electron is transferable, as seen from the upper panel of Fig. 8. In the second process, Eq. (32) always has finite values. The second injected electron is trapped in the dot and it oscillates between \( L \) and \( R \), as shown in the upper and middle panels of Fig. 8. The localized spin also oscillates between \( S_{\uparrow}^{(m)}=-2 \) and \( S_{\uparrow}^{(m)}=-1 \) (see the lower panel of Fig. 8).

In addition, we report that qualitative behaviors identical to those noted above are found for some systems (some \( S \)'s).

**V. COMMENTS**

What follows is a comment about an application of the system with the nonmagnetic \( R \). According to the present study, the system exhibits a spin reversal or nonreversal depending on the exchange integral. The exchange integral is originally described by the orbital energy level and the on-site Coulomb energy in the dot, and transfer integrals between the dot and the QWs. Thereby, by controlling the orbital energy level with the application of the gate voltage, this system may be switchable between the spin reversal and the spin nonreversal.

Second, we propose a model with reversible switching between \( S_{\uparrow}^{-}=S \) and \( S \) (see Fig. 9). \( L \) has energy levels of conduction electrons with up-spin, in which an energy level is located at \( E_{1,L} \). The lowest of the \( N_{L} \) energy levels is located at \( E_{2,L} \). \( R \) has levels of conduction electrons with down-spin, in which a level is located at \( E_{2,R} \) and the lowest of the \( N_{R} \) levels lies at \( E_{1,R} \). Here, tunneling probabilities between the level at \( E_{1,L} \) of \( L \) and that at \( E_{2,R} \) of \( R \) is assumed to be negligibly small. The energy of the highest occupied state (i.e., the Fermi level) of the right electrode is changed by applying the bias voltage, while that of the left electrode is fixed between \( E_{1,L} \) and \( E_{2,L} \). It should be noted that some electrons lying between the energy of the highest occupied state of the left electrode and that of the right electrode contribute to the transport.

We now consider the SET regime as described in Sec. VII. When the bias voltage is applied to the right electrode as shown in Fig. 9(a), the up-spin electrons are injected from \( L \) into the dot and the reversal from \( S_{\uparrow}^{-}=S \) to \( S \) can be induced.
through the interaction of Eq. (2) with $N_1=0$. On the other hand, in the vicinity of $E_{2,R}$, the interaction between the electron and the localized spin is written as

$$V = J'_s \sum_{n=1}^{N_s} (c_{R,n}^{\dagger} c_{L,n} S_n + c_{L,n}^{\dagger} c_{R,n} S_n),$$

(34)

where $R$ ($L_m$) denotes the level of conduction electrons with the down-spin of $R$ (the $n$th level of conduction electrons with the up-spin of $L$), and $J'_s$ is the transverse exchange integral between the localized spin and the electron in this energy region. When the bias voltage is applied to the right electrode as shown in Fig. 9(b), the down-spin electrons are injected from $R$ into the dot and the reversal from $S=\uparrow$ to $\downarrow$ is achieved through the interaction of Eq. (34).

Finally, we discuss the experimental aspects from the viewpoint of the magnitude of current density. In the case of $S=\uparrow$, $N_1=50$, and $J'_s=0.001$ eV, the required maximum current density for the spin reversal, $j_{\text{max}}$, is evaluated to be $j_{\text{max}}=I_{\text{max}}/S_d=4.2 \times 10^8$ A/cm$^2$, where the maximum current $I_{\text{max}}$ is given by $I_{\text{max}}=(5.9 \times 10^{13}) \times (1.6 \times 10^{-19})=9.4 \times 10^{-6}$ A, as shown in the middle panel of Fig. 5, with $n_S S_d=1$ and $e=1.6 \times 10^{-19}$ C. Furthermore, $S_d$ is set to be $S_d=(1.5 \times 10^{-17})^2$ cm$^2$, which is obtained by assuming that the molecule with $S=\uparrow$ has a cubic structure that is about 1.5 nm per side. This length is roughly estimated using examples from a similar molecule, $\text{Mn}_{12}$ with $S=10$. In terms of sustainability, the above mentioned $j_{\text{max}}$ is high for typical ferromagnetic tunnel junctions, such as CoFeB/MgO/CoFeB junctions with critical current densities for the MRSI of $7.8 \times 10^3$ and $1.2 \times 10^7$ A/cm$^2$. On the other hand, it has been recently reported that some carbon nanotubes can individually carry currents with density exceeding $10^9$ A/cm$^2$. We, therefore, anticipate that the appropriate use of carbon nanotubes encapsulating magnetic molecules will lead to the achievement of the spin reversal. In addition, we strongly believe that the current density can be tuned by controlling the exchange integral and $N_1$ (or $N_2$), as found from Eq. (23). Namely, the current density decreases with decreasing magnitude of the exchange integral and $N_1$ (or $N_2$).

VI. CONCLUSION

We studied the localized quantum spin reversal for a case in which up-spin electrons were sequentially injected into the spin quantum dot. To describe the sequentially injected electrons, we first made assumptions about the sequential injection of spins and then proposed a simple method based on approximate solutions from the time-dependent Schrödinger equation. This method was applied to systems with the following $R$: that is, (a) the spin-polarized $R$ having energy levels of conduction electrons with only down-spin, and (b) the nonmagnetic $R$. The respective results are summarized below.

(a) The system exhibited a spin reversal. In particular, we derived the expression of the reversal time of the localized spin and explicitly showed the upper and lower limits of this time for systems with $S \gg 1$. In addition, analytic expressions for the expectation value of the localized spin and the electrical current were obtained as a function of time.

(b) The system of $S=\uparrow$ and $N_1=20$ exhibited the spin reversal or nonreversal depending on the exchange integral. In the spin nonreversal case, the second injected electron was trapped in the dot, although all injected electrons transferred from $L$ to $R$ for the spin reversal case.

We expect that the above-described phenomena will be observed with the advancement of experimental techniques and will be utilized in spin electronics devices in the future.

APPENDIX: BIAS AND GATE VOLTAGES FOR THE SET

The SET region in the plane of the bias and gate voltages for the model of Fig. 1 is found. We investigate the energy change $\Delta E$, which is obtained by subtracting the energy of the initial charge state from that of the final charge state. The change of state really occurs for $\Delta E<0$.

The equivalent circuit for this model is shown in Fig. 10. The bias voltage of the left electrode (the right electrode) is represented by $v_L$ ($v_R$) and the voltage of the gate electrode is $v_g$. The capacitances of junctions 1 and 2, the dot, and the gate are $C_1$, $C_2$, $C_d$, and $C_g$, respectively. The electric charge of the respective junctions is $q_i$ ($i=1-4, d$).

When the initial charge at $L$ ($R$) is represented by $q_L$ ($q_R$), the final charge at $L$ ($R$) is $q'_L$ ($q'_R$), and the change of the charge number in the left electrode (right electrode) is $\Delta n_{Ld}$ ($\Delta n_{Rd}$), the energy change $\Delta E_{q_L,q_R,q'_L,q'_R,\Delta n_{Ld},\Delta n_{Rd}}$ is given by

$$\Delta E_{q_L,q_R,q'_L,q'_R,\Delta n_{Ld},\Delta n_{Rd}} = \Delta U - W_1 - W_2 - W_3 - W_4,$$

(A1)

where $\Delta U$ denotes the change of the electrostatic energy, and $W_1$ ($W_2$) represents the work done by the voltage of the left electrode (the right electrode) and $W_3$ ($W_4$) is that of the left gate electrode (the right gate electrode). These expressions are written as follows:
\[ \Delta U = U' - U, \]  
\[ U = \frac{C_1}{2}(\phi_L - v_L)^2 + \frac{C_2}{2}(v_R - \phi_R)^2 + \frac{C_4}{2}(\phi_R - \phi_L)^2 \]  
\[ + \frac{C_5}{2}(\phi'_L - v_L)^2 + \frac{C_6}{2}(\phi'_R - v_R)^2, \]  
\[ U' = \frac{C_1}{2}(\phi'_L - v_L)^2 + \frac{C_2}{2}(v_R - \phi'_R)^2 + \frac{C_4}{2}(\phi'_R - \phi'_L)^2 \]  
\[ + \frac{C_5}{2}(\phi'_L - v_L)^2 + \frac{C_6}{2}(\phi'_R - v_R)^2. \]  
\[ \eta = \frac{1}{X}(C_d(C_1v_L + C_gv_g) + (C_1 + C_d + C_g)(C_2v_R + C_gv_g)). \]  
\[ x = (C_1 + C_d + C_g)(C_2 + C_d + C_g) - C_d^2. \]  

where \( e (>0) \) is the electric charge. The works \(-e\Delta n_dv_d\) of Eq. (A5) and \( e\Delta n_dv_R \) of Eq. (A6) represent that the electrodes are provided with the charged portion of the charge due to the tunnel electron. Further, \( \phi_L (\phi_R) \) is the electrostatic potential of \( L (R) \), and Eqs. (A13) and (A14) are obtained from the following equations:

\[ q_t = -q_d + q_1 + q_3, \]  
\[ q_R = -q_2 + q_3 + q_4, \]  

with \( q_1 = C_1(\phi_L - v_L), q_2 = C_2(v_R - \phi_R), q_3 = C_g(\phi_R - v_L), q_4 = C_g(\phi_R - v_R), q_d = C_d(\phi_R - \phi_L). \) The bias voltage \( v_L (v_R) \) is now set to be \(-v/2 (v/2)\). When \( \Delta E_{1,1}\) of Eq. (A5) and \( \Delta E_{1,0}\) of Eq. (A6) are equal to zero, the relation between \( v \) and \( v_g \) is given by

\[ v = \frac{-[\lambda(d_1 - d_3) + \nu(d_2 + d_3)]v_g - d_4}{\kappa(d_1 - d_3) + \mu(d_2 + d_3) - \frac{1}{2}(\Delta n_d + \Delta n_L)e}, \]  

with

\[ d_1 = (C_1 + C_g)[\alpha(q'_R - q_R) + \beta(q'_L - q_L)], \]  
\[ d_2 = (C_2 + C_g)[\zeta(q'_R - q_R) + \alpha(q'_L - q_L)], \]  
\[ d_3 = C_d[\zeta - \alpha)(q'_R - q_R) + (\alpha - \beta)(q'_L - q_L)]. \]

FIG. 11. SET region in the bias (v) and gate (v_g) voltage plane for the equivalent circuit with \( v_L = -v/2, v_R = v/2, C_1 = C_2, C_d = 10C_1, C_g = 0.1C_1 \). This region is shown by the shaded area which satisfies \( \Delta E_{0,0,-e,-e,0,1,-e,0,0} < 0, \Delta E_{e,0,-e,0,0,-e,0,1} < 0, \Delta E_{0,0,0,0,0,1} < 0, \Delta E_{0,0,0,0,0,0,1} < 0, \Delta E_{0,0,0,0,0,0,0,1} > 0, \) and \( \Delta E_{0,0,0,0,0,0,0,1} > 0. \) The meaning of each line is as follows: 1, \( \Delta E_{0,0,0,0,0,1,0} = 0; \) 2, \( \Delta E_{e,0,0,0,0,0,0} = 0; \) 3, \( \Delta E_{0,0,0,0,0,0,0,0,1} = 0; \) 4, \( \Delta E_{0,0,0,0,0,0,0,0,1} = 0; \) and 5, \( \Delta E_{0,0,0,0,0,0,0,0,1} = 0, \) where the expression is given by Eq. (A25).
\[ d = \frac{C_0 + C_2}{2} \left[ -\left( \xi q_R + \alpha q_L \right)^2 + \left( \xi q_R + \alpha q_L \right)^2 \right] \]

\[ + \frac{C_1 + C_3}{2} \left[ \left( \alpha q_L + \beta q_R \right)^2 - \left( \alpha q_L + \beta q_R \right)^2 \right] \]

\[ + \frac{C_4}{2} \left[ \left( \xi - \alpha q_R + (\alpha - \beta) q_L \right)^2 \right] \]

\[ - \left( \xi - \alpha q_R + (\alpha - \beta) q_L \right)^2 \], \quad (A29) \]

\[ \kappa = \frac{1}{2X} \left( C_2 C_d - C_1 C_2 - C_1 C_d - C_1 C_g \right), \quad (A30) \]

\[ \lambda = \frac{1}{X} \left( C_2 C_g + 2C_d C_g + C_g^2 \right), \quad (A31) \]

\[ \mu = \frac{1}{2X} \left( C_1 C_2 + C_2 C_d + C_2 C_g - C_1 C_d \right), \quad (A32) \]

This model exhibits the SET under the specific \( v \), which satisfy \( \Delta E_{0,0,0,0} \leq 0 \), \( \Delta E_{-1,0,0,0} \leq 0 \), \( \Delta E_{0,-1,0,0} \leq 0 \), and \( \Delta E_{0,0,-1,0} \geq 0 \). In Fig. 11, the SET region for a system with \( C_1 = C_2 \), \( C_d = 10C_1 \), and \( C_g = 0.1C_1 \) is shown by the shaded area.

We, furthermore, describe the present transport property; that is, when the probability density of the injected electron becomes \( v \) at \( L \) and \( 1 \) at \( R \), the electron moves into the right electrode, while the electron cannot go to the right electrode if the probability density is finite for both \( L \) and \( R \). This property is based on the following two assumptions: First, there is no direct transfer integral between \( L \) and the right electrode. Second, the wave function extended over both \( R \) and the right electrode can be ignored, although that extended over both \( L \) and \( R \) is taken into account, under the condition that the coupling between \( R \) and the right electrode is much smaller than that between \( L \) and \( R \), i.e., Eq. (2).
