ABSTRACT

We study the conductivity and magnetoresistance of the \(\alpha''\prime\prime\prime\) phase solid solution of \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) (\(x = 0.45\)). Single crystals of \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) are obtained by the modified Bridgman method. The space group and tetragonal lattice parameters of single crystals are found to be \(I4_1/amd\) and \(a = b = 8.56(5) \text{Å}, c = 24.16(6) \text{Å}\). The temperature dependence of the conductivity and magnetoresistance is studied in the temperature range of 1.6–320 K and in the presence of a transverse magnetic field from 0 to 10 T. Mixed conductivity is analyzed using Hall resistivity data and standard quantitative mobility spectrum analysis. The concentration and mobility of holes are determined at different temperatures. The presence of two types of holes with different mobilities is demonstrated in the temperature range of 1.6–19 K, while with increasing temperature, just one type of charge carrier is observed in the mobility spectrum.

I. INTRODUCTION

Cadmium and zinc pnictides (including both the semimetal Cd\(_3\)As\(_2\) and the semiconductor Zn\(_3\)As\(_2\)) belong to the class of II–V semiconductor compounds and have a well-defined set of interesting characteristics, including structural, optical, and transport properties.\(^1\) These compounds have long been known as materials with a variety of practical applications,\(^2\) and their properties are the subject of considerable current research activity. Although Cd\(_3\)As\(_2\) and Zn\(_3\)As\(_2\) have similar crystal structures, the ordering of deformed antifluorite cubes differs between them. After the discovery of the topological properties of Cd\(_3\)As\(_2\),\(^6\) considerable research effort was focused on the topological properties of solid solutions of \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\)\(^7\) and solid solutions of dilute magnetic semiconductors based on Cd\(_3\)As\(_2\).\(^8\) On the other hand, composite materials based on Cd\(_3\)As\(_2\) have been investigated owing to their applications in spintronics.\(^9\) It is well known that \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) solid solutions in the composition range \(0 \leq x \leq 0.6\) undergo structural transformations (from the space group \(I4_1/acd\) to \(P4_2/nmc\) and then back to \(I4_1/acd\)) with increasing Zn content.\(^5\) All the studied samples of \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) belong to the tetragonal system \(\alpha''\prime\prime\prime\)-Cd\(_3\)As\(_2\)) and space group \(P4_2/nmc\) (ICSD Database, Version 2009-1, Ref. Code 23 245).\(^9,10\)

In the quasi-binary system Cd\(_3\)As\(_2\)–Zn\(_3\)As\(_2\), there is a continuous series of solid solutions,\(^11\) and the state diagram of Cd\(_3\)As\(_2\)–Zn\(_3\)As\(_2\) shows a region of existence of \(\alpha''\prime\prime\prime\) solid solution phases of \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) in the composition range \(0.45 \leq x \leq 0.65\); this region is a poorly studied area in condensed-matter systems. In Ref. 13, single crystals of \(\alpha''\prime\prime\prime\)-(Zn\(_3\),Cd\(_3\))\(_3\)As\(_2\) (\(x = 0.26\)) were obtained and studied by x-ray diffraction analysis, and the following tetragonal lattice parameters were found: \(a = b = 8.5377(2) \text{Å}, c = 24.0666(9) \text{Å},\) space group \(I4_1/amd,\) and \(Z = 16\).

Although properties such as the electrical conductivity and magnetoresistance of the \(\alpha''\prime\prime\prime\) phases of \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) have not been studied in great detail, it is well known that an increase in the Zn content of solid solutions leads to a transition from the Dirac
semiconductor Cd$_3$As$_2$ to the direct-gap semiconductor Zn$_3$As$_2$. In this case, not only does the type of the majority charge carriers change from $n$ to $p$ but also the nature of the temperature dependence of the electrical conductivity changes. It has been shown in magnetoresistance studies of solid solutions that with increasing Zn content, a transition from topological to ordinary semiconductor properties occurs. Thus, the presence of Shubnikov–de Haas (SdH) oscillations both in the narrow-gap semiconductor Cd$_3$As$_2$ with an inverted band structure and in (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ solid solu-
tions makes it possible to analyze the evolution of the topological properties as the composition changes. Based on the Bodnar model for the semiconductors Cd$_3$As$_2$ and Zn$_3$As$_2$, it is also possible to track the evolution of the band structure from 0.1 to 1.0 eV as well as the changes in the contributions of different groups of charge carriers to the magnetoresistance.

In single crystals of $\alpha'\prime'\prime$-(Cd$_{1-x}$Zn$_x$)$_3$As$_2$ ($x = 0.45$), the magnetic field dependence of the resistivity at different temperatures does not exhibit SdH oscillations, in contrast to compositions with $x \leq 0.38$. For this reason, we have analyzed the mixed conductivity using experimental data on changes in Hall resistivity in the presence of a magnetic field. In this work, we use standard quantitative mobility spectrum analysis (QMSA).

II. EXPERIMENTAL

(Cd$_{1-x}$Zn$_x$)$_3$As$_2$ single crystals with $x = 0.45$ were grown by the modified Bridgeman method from stoichiometric amounts of Cd$_3$As$_2$ and Zn$_3$As$_2$. The crystals under study were slow-cooled at a rate of $5 \degree C/h$ and in the presence of a temperature gradient near the melting point ($T = 853 \degree C$). High degree stoichiometry of the compounds Cd$_3$As$_2$ and Zn$_3$As$_2$ is achieved by additional sublimation in the vapor phase. The composition and homogeneity of the samples were monitored by X-ray powder diffraction (XRD) analysis using a SmartLab diffractometer (Rigaku, Japan) with an angular range from 60° to 80°, step = 0.001, $\nu = 0.5\degree$/min, and a Cu anode ($\lambda = 0.154059$ 290 nm). The (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ single crystals exhibited high crystallinity with tetragonal lattice parameters $a = b = 8.56(5)$ Å, $c = 24.16(6)$ Å, space group $I4_1/amd$, and $Z = 16$.

The XRD pattern of the (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ ($x = 0.45$) powder measured in $\theta$–$2\theta$ mode is shown in Fig. 1. According to the phase diagram of solid solutions of Cd$_3$As$_2$–Zn$_3$As$_2$ in the composition range $x = 0.4–0.8$ at room temperature, a solid solution of (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ can crystallize into the $\alpha''''$ phase with a tetragonal structure (space group $I4_1/amd$), which is related to a fluorite structure. From the coordinates of the basis atoms, obtained in Ref. 13 for a composition with a predominance of zinc arsenide (Zn$_{1-x}$Cd$_x$)$_3$As$_2$, $x = 0.26$, and using the PowderCell program, it was possible to index the main crystallographic planes from which the diffraction occurred.

The matched planes show very good agreement with the peak positions shown in Fig. 1. Thus, a determination of the lattice parameters of the investigated sample (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ ($x = 0.45$) was carried out for the $\alpha''''$ crystal structure, and these were found to be $a = b = 8.56(5)$ Å and $c = 24.16(6)$ Å. These parameters are larger than the values $[a = 8.5377(2)$ Å and $c = 24.0666(9)$ Å] determined in Ref. 13 from x-ray diffraction studies of a solid solution with a lower content of cadmium arsenide, (Zn$_{1-x}$Cd$_x$)$_3$As$_2$ ($x = 0.26$). Zn and Cd ions are randomly distributed in the $\alpha''''$ structure over three independent positions with tetrahedral coordination (fourfold coordination), for which the ionic radii are 0.6 and 0.78 Å, respectively. Therefore, an increase in the degree of substitution of Cd ions for Zn ions leads to an increase in the lattice parameters, a phenomenon that was observed earlier for other polymorphic modifications of Cd$_3$As$_2$–Zn$_3$As$_2$ solid solutions.

The (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ samples were $1 \times 1 \times 5$ mm$^3$ rectangular prisms with soldered thin electrodes. Measurements of the temperature dependence of the magnetoresistance were made in the presence of a transverse magnetic field configuration 0–10 T and over the temperature range of 1.6–320 K using the six-probe method. For measurements, the sample probe was inserted into a He-exchange-gas Dewar, where the temperature could be adjusted with an accuracy of 0.5%. Figure 2 shows the magnetic field dependence of resistivity at different temperatures for (Cd$_{1-x}$Zn$_x$)$_3$As$_2$ ($x = 0.45$).
III. RESULTS AND DISCUSSION

For single-carrier materials, the Hall coefficient and resistivity are defined as

\[ R_H(B) = \frac{1}{nq}, \]  

\[ \rho(B) = \frac{1}{nq\mu}, \]  

respectively, where \( n \) is the carrier concentration, \( \mu \) is the mobility, \( q \) is the carrier charge, and \( B \) is the magnetic field. When there is just one type of carrier, the conductivity tensor is calculated as

\[ \sigma_{xx} = \frac{nq\mu}{1 + \mu^2 B^2}, \]  

\[ \sigma_{xy} = \frac{nq^2 \mu B}{1 + \mu^2 B^2}. \]  

When different types of carriers are present, the carrier mobility and density calculated from Eqs. (1) and (2) are the values averaged over all carriers. For such materials, the specific electrical conductivities of individual carriers are additive, and the total conductivity tensor (for systems with \( N \) carriers) is defined as

\[ \sigma_{xx} = \sum_{j=1}^{N} \frac{n_j q_j \mu_j}{1 + \mu_j^2 B^2}, \]  

\[ \sigma_{xy} = \sum_{j=1}^{N} \frac{n_j q_j^2 \mu_j B}{1 + \mu_j^2 B^2}. \]  

The validity of Eqs. (5) and (6) depends on two assumptions, which do not always hold. First, it is assumed that the carrier concentration and mobility are independent of the magnetic field, but, strictly speaking, this is not always true. For example, a magnetic-field-dependent shift of the energy gap can lead to a significant change in concentration of intrinsic carriers\(^{25}\) or the effective mobility can decrease strongly with increasing magnetic field owing to the phenomenon of magnetic freezing.\(^{26}\) Second, Eqs. (5) and (6) have been obtained from a semiclassical approach, but the discreteness of the Landau levels means that SDH oscillations (and sometimes the quantum Hall effect) are superimposed on classical conductivity. Thus, SDH oscillations often dominate in transport processes at high fields and/or low temperatures and are insignificant at low fields or high temperatures owing to an increased number of collisions and to thermal expansion, respectively. Consequently, the data obtained from the quantum Hall effect are not suitable for rigorous analysis of mixed conductivity when it is not possible to remove SDH oscillations. However, at the same time, SDH oscillations and the quantum Hall effect themselves provide valuable information complementary to that obtained from semiclassical analysis of mixed conductivity.

Mobility spectrum analysis (MSA) considers the conductive spectrum as a function of mobility from the relationship between the conductivity tensor and the magnetic field strength. In this spectrum, each peak value corresponds to the contribution from one of the carriers, and the sign of the mobility indicates the carrier type.\(^{27}\) When applying MSA, it is first assumed that the mobilities of electrons and holes in the samples are continuously distributed. Equations (5) and (6) can then be replaced by integrals,

\[ \sigma_{xx}(B) = \int_{0}^{\infty} \frac{\delta(\mu) + \delta^*(\mu)}{1 + \mu^2 B^2} d\mu, \]  

\[ \sigma_{xy}(B) = \int_{0}^{\infty} \frac{[\delta(\mu) - \delta^*(\mu)]\mu B}{1 + \mu^2 B^2} d\mu. \]  

Dziuba and Górski\(^{28}\) proposed that Eqs. (7) and (8) should be solved by an iterative approximation method. In accordance with this, the integrals in these equations are replaced by Riemann sums,

\[ \sigma_{xx}(B) = \sum_{i=1}^{m} \frac{[\delta(\mu_i) + \delta^*(\mu_i)]\Delta \mu_i}{1 + \mu_i^2 B^2}, \]  

\[ \sigma_{xy}(B) = \sum_{j=1}^{N} \frac{[\delta(\mu_j) - \delta^*(\mu_j)]\mu_j B \Delta \mu_j}{1 + \mu_j^2 B^2}, \]  

where \( m \) is the number of discrete mobilities into which the mobility spectrum is subdivided. The functions \( S_{xx}^\alpha \) and \( S_{xy}^\alpha \) are defined as

\[ S_{xx}^\alpha = \delta(\mu_i) + \delta^*(\mu_i), \]  

\[ S_{xy}^\alpha = \delta(\mu_j) - \delta^*(\mu_j). \]  

The Jacobi iterative method is used to solve Eqs. (9) and (10) and obtain the mobility spectrum. In this method, the range of mobility depends on the magnetic field used for the measurement. The upper and lower bounds satisfy the conditions \( 1/\mu_{\text{exp}} \leq \mu \leq 1/\mu_{\text{exp}} \). In accordance with the Jacobi iterative procedure, Eqs. (9)–(12) are transformed into the form

\[ S_{xx}^\alpha = \left( 1 + \mu_i^2 B^2 \right) \left[ \sigma_{xx}^{\text{exp}}(B_i) - \sum_{j=1}^{i-1} S_{xx}^\alpha(B_j) \sigma_{xx}^{\text{exp}}(B_i) - \sum_{j=i+1}^{m} S_{xx}^\alpha(B_j) \right], \]  

\[ S_{xy}^\alpha = \left( 1 + \mu_i^2 B^2 \right) \left[ \sigma_{xy}^{\text{exp}}(B_i) - \sum_{j=1}^{i-1} S_{xy}^\alpha(B_j) \sigma_{xy}^{\text{exp}}(B_i) - \sum_{j=i+1}^{m} S_{xy}^\alpha(B_j) \right]. \]  

At each point of the subregion, the carrier parameters are determined by the linear least squares method,

\[ \chi^2 = \sum_{i=1}^{m} \left( \sigma_{xx}^{\text{exp}}(B_i) - \sum_{j=1}^{N} \sigma_{xx}^{\alpha}(B_j) \right)^2 + \left( \sigma_{xy}^{\text{exp}}(B_i) - \sum_{j=1}^{N} \sigma_{xy}^{\alpha}(B_j) \right)^2. \]  

The subregion point with the minimum value is used as the initial approximation, and the Goldstein–Armijo rule is used to select the
step. Then, to accelerate convergence, the relaxation method is used to solve the linear equations (13) and (14),

\[
S_{xx}^i(k+1) = (1 - \omega_{xx})S_{xx}^i(k) + \omega_{xx}\left(1 + \mu_i^2B_i^2\right) \\
\times \left[\sigma_{xx}^{\exp}(B_i) - \frac{\sum_{j=1}^{i-1} S_{xx}^j(k+1)}{1 + \mu_j^2B_j^2} - \frac{m}{1 + \mu_i^2B_i^2}\right], \quad (16)
\]

and

\[
S_{xy}^i(k+1) = (1 - \omega_{xy})S_{xy}^i(k) + \omega_{xy}\left(1 + \mu_i^2B_i^2\right) \\
\times \left[\sigma_{xy}^{\exp}(B_i) - \frac{\sum_{j=1}^{i-1} S_{xy}^j(k+1)}{1 + \mu_j^2B_j^2} - \frac{m}{1 + \mu_i^2B_i^2}\right], \quad (17)
\]

where \(S_{xx}^i(k)\) and \(S_{xy}^i(k)\) are the results from the \(k\)th iteration step, and both \(\omega_{xx}\) and \(\omega_{xy}\) give the convergence rate of the iterative procedure (the relaxation rate). To determine the optimal value of \(\omega_{xx}\), the following estimation procedure is used.\textsuperscript{29}

If \(\Delta S_{xx}^i = S_{xx}^i(k+1) - S_{xx}^i(k)\) is the change during the \(k\)th iteration performed without relaxation (i.e., with \(\omega_{xx} = 1\)), then

\[
(\omega_{xx})_{opt} \approx \frac{2}{1 + \sqrt{1 - (\Delta S_{xx}^i(k+p)/\Delta S_{xx}^i(k))^{1/p}}}, \quad (18)
\]

where \(p\) is a positive integer [the value of \((\omega_{xy})_{opt}\) is determined analogously].

Figure 3 shows the QMSA spectra of \((Cd_{1-x}Zn_x)_2As_2\) \((x = 0.45)\) at 1.6, 19, 40, and 120 K. In the spectra, the concentration of each type of carrier \(j\) is

\[
n_j = \frac{\sum_{i=1}^{k} (\sigma_i - \sigma_{i-1})}{(e\mu_i)},
\]

i.e., the weighted sum of all carriers for the \(j\)th peak. The bulk concentrations of carriers and their mobilities are shown in Table I. It can be seen that there are two types of holes with different mobilities in the temperature range of 1.6–19 K; however, with increasing temperature, just one type of carrier is observed. It can be assumed...
that up to about 19 K, \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) \((x = 0.45)\) contains two types of holes, namely, light and heavy holes. The concentration of heavy carriers is almost constant between 16 and 19 K and then increases rapidly with increasing temperature above 40 K, whereas their contribution to conductivity decreases and is no longer visible in the mobility spectrum. Our results are in qualitative agreement with those of the Bodnar model. That model is a generalization of the three-level Kane model for narrow-gap semiconductors with a tetragonal crystal structure within the \(\Gamma p\) approximation and is used to describe the band structure of many \(\text{II}-\text{V}_2\) semiconductors, such as \(\text{Cd}_3\text{As}_2\) and \(\text{Zn}_3\text{As}_2\). According to the band structure model, the direct-gap \(p\)-type semiconductor \(\text{Zn}_3\text{As}_2\) contains bands of both light and heavy holes,\(^{1}\) which is consistent with our results.

### IV. CONCLUSIONS

Using the modified Bridgman method, we have obtained single crystals of the \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) \((x = 0.45)\) solid solution. We have found by powder x-ray analysis that the single crystals belong to the \(\alpha''''\) phase with space group \(I4_1/amd\) and lattice parameters \(a = b = 8.56(5)\ \text{Å}\) and \(c = 24.16(6)\ \text{Å}\). We are the first to study the temperature dependence of the electrical conductivity and magnetoresistance of the \(\alpha''''\) phase of the \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) solid solution in the temperature range of 1.6–320 K and in the presence of a magnetic field from 0 to 10 T. The spectrum of charge carriers (Fig. 3) has been analyzed in the temperature range of 1.6–120 K by the QMSA method. It has been found that at temperatures above 40 K, whereas their contribution to conductivity decreases and is no longer visible in the mobility spectrum. The mobility of heavy carriers decreases with increasing temperature above 40 K (Table I).

### TABLE I. Concentrations and mobilities of carriers for \((\text{Cd}_{1-x}\text{Zn}_x)_3\text{As}_2\) \((x = 0.45)\) at different temperatures.

| Temperature (K) | Concentration \((\text{cm}^{-3})\) | Mobility \((\text{cm}^2\ \text{V}^{-1}\ \text{s}^{-1})\) |
|----------------|-----------------------------|-----------------------------|
|                | Heavy \(1.6 \times 10^{18}\)  | Light \(7.7 \times 10^{17}\) |
| 19             | \(1.7 \times 10^{17}\)       | \(5.2 \times 10^{17}\)     |
| 40             | \(5.2 \times 10^{16}\)       | \(1.2 \times 10^{6}\)      |
| 120            | \(7.7 \times 10^{18}\)       | \(1.2 \times 10^{6}\)      |
