Abstract

Background and Aim. Migraine is a common form of headache that affects patients quality of life negatively. In addition to pharmacologic treatment, there are a variety of nonpharmacologic treatments for migraine headache. In present study, we examined the effect of prayer on intensity of migraine pain.

Methods. In a prospective, randomized, controlled trial from October 2013 to June 2014, this study has been conducted in Kerman, Iran. We randomly assigned 92 patients in 2 groups to receive either 40 mg of propranolol twice a day for 2 month (group “A”) or 40 mg of propranolol twice a day for 2 months with prayer (group “B”). At the beginning of study and 3 months after intervention, patients’ pain was measured using the visual analogue scale. Results. At the beginning of study and before intervention, the mean score of pain in patients in groups A and B were 5.7 ± 1.6 and 6.5 ± 1.9, respectively. According to results of independent t test, mean score of pain intensity at the beginning of study were similar between patients in 2 groups (P > .05). Three month after intervention, mean score of pain intensity decreased in patients in both groups. At this time, the mean scores of pain intensity were 5.4 ± 1.1 and 4.2 ± 2.3 in patients in groups A and B, respectively. This difference between groups was statistically significant (P < .001).

Conclusions. The present study revealed that prayer can be used as a nonpharmacologic pain coping strategy in addition to pharmacologic intervention for this group of patients.

complementary therapies, alternative therapies, pain intensity, migraine headache

Received September 6, 2015. Received revised November 29, 2015. Accepted for publication December 12, 2015.

The use of alternative medicine for illness is common among people in several countries with different religion and cultural background. A report of the National Center for Complementary and Alternative Medicine in 2002 showed that prayer for self (43%) and prayer for others (24.4%) are the 2 most commonly used alternative medicine practice in the United States.1

Use of prayer as an alternative treatment during time of illness received great attention by researchers in previous decade. In one study in this regard, Matthews et al2 examined the effects of intercessory prayer on patients with rheumatoid arthritis. Results of the study by Matthews et al2 showed that patients receiving in-person intercessory prayer showed significant overall improvement during 1-year follow-up. Matthews et al2 concluded that in-person intercessory prayer may be a useful adjunct to standard medical care for certain patients with rheumatoid arthritis. In the other study, Coleman et al3 examined the association of gender to use of prayer as a self-care strategy for managing the human immunodeficiency virus (HIV)-related symptoms of fatigue, nausea, depression, and anxiety among 448 African American men and women with HIV. Results of the study by Coleman et al3 showed that prayer is used as a self-care strategy by more 50% of the respondents for 3 of the 4 symptoms and is rated highly efficacious. In a randomized, blinded study, Olver and Dutney4 examined the effects of intercessory prayer on spiritual well-being in patients with cancer. Results of the study by Olver and Dutney4 showed that intercessory prayer significantly improved spiritual well-being in this group of patients.

The fourth leading cause of patients visits in the United States emergency departments are related to headache. Migraine is a common form of headache that remains an important public health problem. Recently Burch et al. reported that 14.2% of the adults population in the United States suffers from some degree of migraine. In another study in this regard in the United States, Tepper reported that 8.7 million females and 2.6 million males suffer from migraine headache with moderate to severe disability. Pharmacologic therapies are the mainstay of migraine treatment. However, in recent years, some nonpharmacologic, alternative and complementary therapies, such as biofeedback, cognitive therapies, aerobic exercise, relaxation training, and acupuncture have been proposed for use in combination with pharmacologic therapies. In one study, Dittrich et al. examined effects of aerobic exercise with relaxation on migraine patients’ level of pain. They reported that patients’ migraine pain intensity reduced significantly after implemented aerobic exercise with relaxation program.

One of the most commonly used alternative medicine procedures that traditionally used by people both in relation to their own health and the health of others is prayer. The aim of this study was to examine the effect of prayer on intensity of pain in migraine patients.

**Methods**

This study is a double blind randomized controlled trial conducted from October 2013 to January 2014 in Kerman, Iran. This study has received permissions from deputy of research and also the ethics board of the Kerman University of Medical Sciences. Each patient was asked to fill in a written consent form (previously approved by ethics committees). In addition, all participants were promised that all data would remain anonymous, kept confidential, and be stored safely.

With regard to our pilot study and considering a power of 95% (beta) and $P = .05$ (alpha), the sample size would be 36 in each group (total 82). For increasing power of our finding we obtained 92 samples for present study. Samples were 92 patients suffering from some degree of migraine. In another study in this regard in the United States, Tepper reported that 8.7 million females and 2.6 million males suffer from migraine headache with moderate to severe disability. Pharmacologic therapies are the mainstay of migraine treatment. However, in recent years, some nonpharmacologic, alternative and complementary therapies, such as biofeedback, cognitive therapies, aerobic exercise, relaxation training, and acupuncture have been proposed for use in combination with pharmacologic therapies. In one study, Dittrich et al. examined effects of aerobic exercise with relaxation on migraine patients’ level of pain. They reported that patients’ migraine pain intensity reduced significantly after implemented aerobic exercise with relaxation program.

One of the most commonly used alternative medicine procedures that traditionally used by people both in relation to their own health and the health of others is prayer. The aim of this study was to examine the effect of prayer on intensity of pain in migraine patients.

### Results

All patients who participate in present study were Muslim. Of the 92 patients, 82 were women. The mean age of all patients was $33.7 \pm 10.3$ years. Most patients were married (75%). The demographic characteristics including age, sex, level of education, and time of migraine diagnosis were similar in both groups of patients ($P > .05$) (Table 1) (Table 2).

At the beginning of study and before intervention, the mean score of pain in patients in groups A and B were $5.7 \pm 1.6$ and $6.5 \pm 1.9$, respectively. According to results of the independent $t$ test, mean score of pain intensity at the beginning of study were similar between patients in 2 groups ($P > .05$). Three months after intervention, the mean score of pain intensity decreased in patients in both groups. In this time, the mean score of pain intensity were $5.4 \pm 1.1$ and $4.2 \pm 2.3$ in patients in groups A and B, respectively. This difference between groups was statistically significant ($P < .001$) (Figure 1).

### Discussion

In addition to pharmacologic treatment, there are a variety of nonpharmacologic treatments for headache. Religious
activity may be one of several pain coping strategies to manage suffering. In the present study, we examined the effect of prayer as a nonpharmacologic method in alleviating migraine pain. According to finding of present study prayer have positive effect on reducing migraine pain.

According to definition of the National Center for Complementary and Alternative Medicine, “prayer is an active process of communicating with and appealing to a higher spiritual power.” The word of “prayer” and its derivatives, which have been mentioned several times in the Holy Quran (holy book of the Muslims), are rooted in “pray” and means “asking for something,” “making a request for a need,” and “seeking help.” There are several types of prayer, including conversational prayer, meditative prayer, ritual prayer, and intercessory prayer. Intercessory prayer is one type of prayer that is organized, regular, and committed to setting time aside with the belief that the prayers are communicating with God. Results of previous studies showed that religious activity have positive effect on physical and mental health. In a review study in this regards, Coruh et al reported that religious intervention such as intercessory prayer may improve success rates of in vitro fertilization, decrease length of hospital stay and duration of fever in septic patients, increase immune function, improve rheumatoid arthritis, and reduce anxiety and complications in patients with heart disease.

The use of complementary and alternative medicine among migraine patients is a growing phenomenon. Results of one study in this regard showed that 31.4% of migraine patients used complementary and alternative medicine. This study also showed that most common reason for deciding to try a complementary and alternative medicine therapy was that it offered a “potential improvement of headache” (47.7%). Although use of prayer tested in different clinical setting, previous studies about use of prayer for migraine pain are limited. Recently, in one study, researchers examined the effect of different meditation types on headache frequency, headache severity, and pain medication among patients with migraine headache. They randomly assigned 92 patients to 1 of 4 groups: (1) spiritual meditation, (2) internally focused secular meditation, (3) externally focused secular meditation, and (4) progressive muscle relaxation. Results of this study showed that migraine frequency and migraine medication usage decreased in patients who received the spiritual meditation in compared to patients who received other type of meditation. In another study in this regard, Wachholtz and Pargament compared effect of spiritual meditation, internally focused secular meditation, externally focused secular meditation, and muscle relaxation on pain tolerance, headache frequency, and mental and spiritual health variables. Results of Wachholtz and Pargament showed that spiritual meditation had greater effect in decreasing patients frequency of migraine headaches, anxiety, and negative effect, as well as greater increases in pain tolerance, headache-related self-efficacy, daily spiritual experiences, and existential well-being.

Conclusion
Migraine pain is bad experiences that affect patients quality of life negatively. The present study revealed that prayer can be used as a nonpharmacologic pain coping strategy in addition to pharmacologic intervention for this group of patients.

Author Contributions
The work presented here was carried out through collaboration between all authors. HT and NZ defined the research theme. HT, NZ and KD designed methods, ZE and HR collected data, HS analyzed the data, interpreted the results. All authors have contributed to, seen, and approved the article.

Declaration of Conflicting Interests
The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding
The authors received no financial support for the research, authorship, and/or publication of this article.

Ethical Approval
The work was approved by the Ethics Committee of Kerman University of Medical Sciences.
