Abstract A source of contaminated groundwater is governed by the disposal of waste material on a landfill. There are many people in rural areas where the primary source of drinking water is well water. This well water may be contaminated with groundwater from landfills. In this research, a two-dimensional mathematical model for long-term contaminated groundwater pollution measurement around a landfill is proposed. The model is governed by a combination of two models. The first model is a transient two-dimensional groundwater flow model that provides the hydraulic head of the groundwater. The second model is a transient two-dimensional advection-diffusion equation that provides the groundwater pollutant concentration. The proposed explicit finite difference techniques are used to approximate the hydraulic head and the groundwater pollutant concentration. The simulations can be used to indicate when each simulated zone becomes a hazardous zone or a protection zone.

Keywords Groundwater Pollution, Landfill, Contamination, Finite Difference Method, Two-dimensional

1 Introduction

The importance of the utilization of groundwater resources continues to grow due to the increasing requirement for water for irrigation, drinking, commercial, agricultural and industrial proposes. From this, we can see that water become an even more important part of human life. What is the effect of contaminated water on humans? Contaminated groundwater can enter the food chain and cause many life-threatening diseases and problems. The effect of drinking contaminated or dirty water causes waterborne disease. Contaminated water can cause many types of diarrheal diseases, including Cholera, and other serious illnesses, such as Guinea worm disease, Typhoid and Dysentery. The solution to this problem is to approximate when the water from the primary source of drinking will become a hazardous zone. Hence, sustainable management planning must be developed for groundwater systems. In general, the level of pollution in groundwater can be ascertained from field data sites. However, this is rather complicated, and the results obtained tentatively deviate in measurement from one point in each time/place.

In [3], the modified MacCormack scheme improved accuracy in water quality measurement in a nonuniform water flow in a stream. A mathematical model was used to simulate a water current and the elevation in a uniform reservoir in [6]. There was some research that concerned solving the dispersal of pollutants in a river in [8]. Groundwater models and their application were represented in [1, 2]. Transient groundwater modeling using spreadsheet simulation can be solved by using the finite difference method, which was described in [1]. The results are combined with MODFLOW results, a well-known model code for groundwater modeling. The objective of [2] was to propose a simple and flexible difference method and consider the complex geometry by using grid sizes aquifer parameters, sinks, and source terms. In this research, we consider groundwater that has been contaminated by waste material on a landfill. The simulation of the contaminated groundwater pollution model required data concerned with the velocity of the current points and any time in the domain. The transient two-dimensional groundwater flow model provided the velocity field of the groundwater. We used the transient two-dimensional advection-diffusion equation to approximate the groundwater pollutant concentration. The finite difference [9, 10, 11] and finite elements methods [12, 13, 14] are the most popular numerical solution techniques. Among of these, finite difference methods, including both explicit and implicit schemes, are mostly used for two-dimensional domain such as in latitude and longitude stream.

These two mathematical models were used to simulate contaminated groundwater pollution. The first was a transient
two-dimensional groundwater flow model that provided the hydraulic head of the groundwater. The second was a transient two-dimensional advection-diffusion equation that gave the groundwater pollutant concentration. Both of the models were formulated in two-dimensional equations. The explicit method was used in both models. For each time, the calculated flow velocity fields of the first model were inputted into the second model as the field data.

2 Governing equation

2.1 Transient groundwater flow model

The governing equation of a latitudinally integrated Darcy’s flow in a two-dimensional advection-diffusion equation [1],

\[ \frac{\partial H(x, z, t)}{\partial t} = \frac{\partial}{\partial x} \left( K_x \frac{\partial H(x, z, t)}{\partial x} \right) + \frac{\partial}{\partial z} \left( K_z \frac{\partial H(x, z, t)}{\partial z} \right) \] (2.1)

where \( H(x, z, t) \) is the hydraulic head(metre), \( S \) matrix of specific storage(1/metre), \( L_x \) is the considered area length, \( L_z \) is the depth of considered groundwater area, \( T \) is the stationary time of simulation as shown in Figure 1. The hydraulic conductivity(metre/day) component in the \( x \), \( z \) directions are denoted by \( K_x \), \( K_z \), respectively. Assuming that the soil topography in the considered area is homogeneous, these mean that the hydraulic conductivity are constant.

\[ S \frac{\partial H(x, z, t)}{\partial t} = K_x \frac{\partial^2 H(x, z, t)}{\partial x^2} + K_z \frac{\partial^2 H(x, z, t)}{\partial z^2} \] (2.2)

for all \((x, z, t) \in \Omega \) such that \( \Omega = [0, L_x] \times [0, L_z] \times [0, T] \).

2.2 Initial and boundary condition of transient groundwater flow model

2.2.1 The initial condition of transient groundwater flow model

The initial condition is defined by an interpolation function of measured raw data as be low

\[ H(x, z, 0) = h(x, z), \] (2.3)

where \( h(x, z) \) is a given potential hydraulic head function.

2.2.2 The boundary conditions

The top, right and bottom boundary conditions are assumed by the averaged rate of change of hydraulic head around the top, right and bottom boundaries. The left boundary condition is assumed by the interpolation function of measured raw data in the considered landfill as shown in Figure 1. The boundary condition, are also assumed by

\[ h(x, z, t) = h_L(z), \quad \text{for all } z \in [0, L_z] \text{ and } x = 0, \] (2.4)

\[ \frac{\partial h(x, z, t)}{\partial z} = h_T(x), \quad \text{for all } x \in [0, L_x] \text{ and } z = 0, \] (2.5)

\[ h(x, z, t) = h_R(z), \quad \text{for all } z \in [0, L_z] \text{ and } x = 0, \] (2.6)

\[ \frac{\partial h(x, z, t)}{\partial z} = h_B(x), \quad \text{for all } x \in [0, L_x] \text{ and } z = 0, \] (2.7)

where \( h_L(z), h_T(x), h_R(z) \) and \( h_B(x) \) are the boundary source of hydraulic head on the left boundary domain. The rate of change hydraulic head with respect to domain boundaries around the top, the bottom and the right bottom around the considered area as shown in Figure 3, respectively.

2.3 Groundwater flow velocity model

We can obtain that the groundwater flow velocity in \( x \)-direction is a decreasing rate of change of the hydraulic head \( x \)-direction,

\[ u = -\frac{\partial H}{\partial x}. \] (2.8)

Similarly, the groundwater flow velocity in \( z \)-direction is a decreasing rate of change of the hydraulic head in \( z \)-direction,

\[ w = -\frac{\partial H}{\partial z}. \] (2.9)

2.4 A horizontal averaged contaminated groundwater dispersion model

A horizontal averaged two-dimensional advection-diffusion equation (ADE) is expressed as follow

\[ \frac{\partial c(x, z, t)}{\partial t} + u \frac{\partial c(x, z, t)}{\partial x} + w \frac{\partial c(x, z, t)}{\partial z} = D_x \frac{\partial^2 c(x, z, t)}{\partial x^2} + D_z \frac{\partial^2 c(x, z, t)}{\partial z^2} + Q, \] (2.10)
for all \((x, z, t) \in \Omega\) such that \(\Omega = [0, L_x] \times [0, L_z] \times [0, T]\), where \(c(x, z, t)\) is the groundwater pollutant concentration (kg/m³), \(D_x, D_z\) are the diffusion coefficient in \(x\)- and \(z\)-directions and \(u(x, z, t), w(x, z, t)\) are the groundwater flow velocity in the \(x\)- and \(z\)-directions.

2.5 Initial and boundary conditions of the contaminated groundwater dispersion model

2.5.1 Initial condition of the contaminated groundwater dispersion model

The initial condition is defined by an interpolation function of the potential groundwater pollutant concentration,

\[ c(x, z, 0) = c_0(x, z). \tag{2.11} \]

for all \((x, z) \in [0, L_x] \times [0, L_z]\).

2.5.2 The boundary conditions

The left boundary condition is assumed by the interpolation function of measured raw data at the considered landfill. The top, right and bottom boundary conditions are assumed by the values of the potential groundwater pollutant concentration at the considered landfill. The averaged rates of change of pollutant concentration around the top, right and bottom boundaries. The boundary conditions are also assumed by

\[ c(L_x, x, t) = g_N(x), \quad \text{for all } x \in [k_1 L_x, k_2 L_x], \tag{2.12} \]

\[ \frac{\partial c(z, 0, t)}{\partial x} = g_L(z), \quad \text{for all } z \in [0, L_z] \text{ and } t \in [0, T], \tag{2.13} \]

\[ \frac{\partial c(L_z, x, t)}{\partial z} = g_T(x), \quad \text{for all } x \in [0, L_x] \cup (k_2 L_x, L_x] \text{ and } t \in [0, T], \tag{2.14} \]

\[ \frac{\partial c(z, L_z, t)}{\partial x} = g_R(z), \quad \text{for all } z \in [0, L_z] \text{ and } t \in [0, T], \tag{2.15} \]

\[ \frac{\partial c(x, 0, t)}{\partial z} = g_B(x), \quad \text{for all } x \in [0, L_x] \text{ and } t \in [0, T], \tag{2.16} \]

where \(k_1 L_x, k_2 L_x\) are referred to the range area of the groundwater pollutant area source, and \(g_L(z), g_T(x), g_R(z)\) and \(g_B(x)\) are the rate of change pollutant concentration with respect distance around the top, the bottom and the right boundaries along the considered area, respectively.

3 Numerical techniques

In this paper, we will propose finite difference methods to the transient groundwater model by using the forward time central space method. We now discretize the domain by dividing the interval \([0, L_x]\) and \([0, L_z]\) into \(M_x\) and \(M_z\) subintervals such that \(M_x \Delta x = L_x, M_z \Delta z = L_z\) and the time interval \([0, T]\) into \(N\) subintervals such that \(N \Delta t = T\). The grid points \((x_i, z_j, t_n)\) are defined by \(x_i = i \Delta x\) for all \(i = 1, 2, ..., M_x, z_j = j \Delta z\) for all \(j = 1, 2, ..., M_z\) and \(t_n = n \Delta t\) for all \(n = 1, 2, ..., T\). We can then approximate \(H(x_i, z_j, t_n)\) by \(H^n_{i,j}\) value of the difference approximation of \(H(x, z, t)\) at point \(x = i \Delta x, z = j \Delta z\) and \(t = n \Delta t\), where \(0 \leq i \leq M_x, 0 \leq j \leq M_z\) and \(0 \leq n \leq N\) which \(M_x, M_z, N\) are positive integers.

3.1 Explicit finite difference method for two-dimensional groundwater flow model

Taking the central difference in space and forward difference in time into scheme each terms of Eq. (2.2), we have

\[ H(x, z, t) \simeq H^n_{i,j}, \tag{3.1} \]

\[ \frac{\partial H}{\partial t} \bigg|_{(x_i, z_j, t_n)} \simeq \frac{H^n_{i,j} - 1 - H^n_{i,j-1}}{\Delta t}, \tag{3.2} \]

\[ \frac{\partial^2 H}{\partial x^2} \bigg|_{(x_i, z_j, t_n)} \simeq \frac{H^n_{i+1,j} - 2H^n_{i,j} + H^n_{i-1,j}}{\Delta x^2}, \tag{3.3} \]

\[ \frac{\partial^2 H}{\partial z^2} \bigg|_{(x_i, z_j, t_n)} \simeq \frac{H^n_{i,j-1} - 2H^n_{i,j} + H^n_{i,j+1}}{\Delta z^2}. \tag{3.4} \]

Substituting Eqs. (3.1)-(3.4) into Eq. (2.2), we get the finite equation,

\[ S \left( \frac{H^n_{i,j+1} - H^n_{i,j}}{\Delta t} \right) = K_x \left( \frac{H^n_{i+1,j} - 2H^n_{i,j} + H^n_{i-1,j}}{\Delta x^2} + K_z \left( \frac{H^n_{i,j-1} - 2H^n_{i,j} + H^n_{i,j+1}}{\Delta z^2} \right) \right), \tag{3.5} \]

for all \(i = 1, 2, 3, ..., M_x, j = 1, 2, 3, ..., M_z\) and \(n = 1, 2, 3, ..., N - 1\). Then the explicit finite difference equation becomes

\[ H^{n+1}_{i,j} = \alpha H^n_{i,j-1} + \alpha H^n_{i+1,j} + (1 - 2\alpha - 2\beta)H^n_{i,j} + \beta H^n_{i-1,j} + \beta H^n_{i+1,j}, \tag{3.6} \]
where \( \alpha = \frac{K_x(\Delta t)}{S(D\Delta z)^2} \) and \( \beta = \frac{K_z(\Delta t)}{S(D\Delta z)^2} \), for all \( i = 1, 2, ..., M_x - 1 \) and \( j = 1, 2, ..., M_z - 1 \). According to the right boundary condition Eqs.(2.5) - (2.7), substituting the approximated unknown value to each boundaries,

For \( j = M_x \) and \( 0 < i < M_z - 1 \) at \( t > 0 \), letting that
\[
H^n_{i,M_x+1} = H^n_{i,M_x} + f_R(z)\Delta x.
\] (3.7)

It follow that
\[
H^{n+1}_{i,M_x} = \alpha H^n_{i,M_x-1} + (1 - \alpha - 2\beta)H^n_{i,M_x} + \beta H^n_{i+1,M_x} + \alpha f_R(z)\Delta x.
\] (3.8)

For \( i = 0 \) and \( 0 < j < M_x - 1 \) at \( t > 0 \), letting that
\[
H^n_{0,j} = H^n_{0,j-1} - \beta f_B(x)\Delta z.
\] (3.9)

It follow that
\[
H^{n+1}_{0,j} = \alpha H^n_{0,j-1} + \alpha H^n_{0,j+1} + (1 - 2\alpha - \beta)H^n_{0,j}
+ \beta H^n_{1,j} - \beta f_B(x)\Delta z.
\] (3.10)

For \( i = M_x \) and \( 0 < j < M_x - 1 \) at \( t > 0 \), letting that
\[
H^{n+1}_{M_x,j} = H^n_{M_x,j} + f_T(x)\Delta z.
\] (3.11)

It follow that
\[
H^{n+1}_{M_x,j} = \alpha H^n_{M_x-1,j} + \alpha H^n_{M_x,j+1} + (1 - 2\alpha - \beta)H^n_{M_x,j}
+ \beta H^n_{M_x-1,j} - \beta f_T(x)\Delta z.
\] (3.12)

### 3.2 Finite difference method for groundwater flow velocity model

Taking the forward difference in space into Eq.(2.8) and Eq.(2.9), we have
\[
v(x, z, t) \approx v^n_{i,j},
\] (3.13)

\[
w(x, z, t) \approx w^n_{i,j},
\] (3.14)

\[
\left. \frac{\partial H}{\partial x}\right|_{(x,z,t_n)} \approx \frac{H^n_{i+1,j} - H^n_{i,j}}{\Delta x},
\] (3.15)

\[
\left. \frac{\partial H}{\partial z}\right|_{(x,z,t_n)} \approx \frac{H^n_{i+1,j} - H^n_{i,j}}{\Delta z}.
\] (3.16)

Substituting Eqs.(3.15) - (3.16) into (2.8) and (2.9), we get the finite equation,
\[
v^n_{i,j} = -\frac{1}{\Delta x}(H^n_{i+1,j} - H^n_{i,j}),
\] (3.17)

and
\[
w^n_{i,j} = -\frac{1}{\Delta z}(H^n_{i+1,j} - H^n_{i,j}).
\] (3.18)

### 3.3 Explicit finite difference method for two-dimensional groundwater pollution dispersion model

In this section, the considered domain is defined in a similar grid spacing as the previous. We will employ forward time central space difference scheme (FTCS) to Eqs.(2.10)

\[
c(x, z, t) \approx C^n_{i,j},
\] (3.19)

\[
\left. \frac{\partial c}{\partial t}\right|_{(x,z,t_n)} \approx \frac{C^n_{i,j} - C^{n-1}_{i,j}}{\Delta t},
\] (3.20)

\[
\left. \frac{\partial c}{\partial x}\right|_{(x,z,t_n)} \approx \frac{C^n_{i+1,j} - C^n_{i,j}}{2\Delta x},
\] (3.21)

\[
\left. \frac{\partial c}{\partial z}\right|_{(x,z,t_n)} \approx \frac{C^n_{i,j+1} - C^n_{i,j}}{2\Delta z},
\] (3.22)

\[
\left. \frac{\partial^2 c}{\partial x^2}\right|_{(x,z,t_n)} \approx \frac{C^n_{i+1,j} - 2C^n_{i,j} + C^n_{i-1,j}}{(\Delta x)^2},
\] (3.23)

\[
\left. \frac{\partial^2 c}{\partial z^2}\right|_{(x,z,t_n)} \approx \frac{C^n_{i,j+1} - 2C^n_{i,j} + C^n_{i,j-1}}{(\Delta z)^2}.
\] (3.24)

Substituting Eqs.(3.19) - (3.24) into (2.10), we get the finite equation,
\[
\frac{C^n_{i,j} - C^n_{i,j}}{\Delta t} + u^n_{i,j} \left( \frac{C^n_{i+1,j} - C^n_{i,j}}{2\Delta x} \right) + w^n_{i,j} \left( \frac{C^n_{i,j+1} - C^n_{i,j}}{2\Delta z} \right)
= D_x \left( \frac{C^n_{i,j} - 2C^n_{i,j} + C^n_{i,j+1}}{(\Delta x)^2} \right)
+ \frac{D_x}{\Delta x} \left( \frac{C^n_{i,j} - 2C^n_{i,j} + C^n_{i,j+1}}{(\Delta x)^2} \right)
+ Q,
\] for all \( i = 1, 2, 3, ..., M_x, j = 1, 2, 3, ..., M_z \) and \( n = 1, 2, 3, ..., N - 1 \). Then the explicit finite difference equation becomes
\[
C^{n+1}_{i,j} = (\tau_1 + \tau_2)C^n_{i-1,j} + (\lambda_1 + \lambda_2)C^n_{i,j-1} + (1 - 2\lambda_1 - 2\tau_1)C^n_{i,j}
+ (\tau_1 - \tau_2)C^n_{i+1,j} + (\lambda_1 - \lambda_2)C^n_{i,j+1} + Q\Delta t,
\] (3.25)

where \( \lambda_1 = \frac{D_x\Delta t}{(\Delta x)^2} \), \( \lambda_2 = \frac{u^n_{i,j}\Delta t}{2\Delta x} \), \( \tau_1 = \frac{D_x\Delta t}{(\Delta z)^2} \) and \( \tau_2 = \frac{w^n_{i,j}\Delta t}{2\Delta z} \).

According to the boundary condition Eqs.(2.13)-(2.16), substituting the approximate unknown value of the each boundary,

For \( j = 0 \) and \( 0 < i < M_x - 1 \) at \( t > 0 \), letting that
\[
C^n_{i,-1} = C^n_{i,0} - g_W(z)\Delta x.
\] (3.26)

\[
C^{n+1}_{i,0} = (\tau_1 + \tau_2)C^n_{i,-1,0} + (1 - \lambda_1 - 2\tau_1 - \tau_2)C^n_{i,0}
+ (\tau_1 - \tau_2)C^n_{i+1,0} + (\lambda_1 - \lambda_2)C^n_{i,1} + Q\Delta t
- (\lambda_1 - \lambda_2)g_L(z)\Delta x.
\] (3.27)

For \( j = M_z \) and \( 0 < i < M_x - 1 \) at \( t > 0 \), letting that
\[
C^n_{i,M_z+1} = C^n_{i,M_z} + g_R(z)\Delta x.
\] (3.28)
It follow that
\[ C_{i,M_z}^{n+1} = (\tau_1 + \tau_2) C_{i-1,M_z}^n + (1 - \lambda_1 - 2\tau_1 - \tau_2) C_{i,M_z}^n + (\lambda_1 - \lambda_2) g_B(x) \Delta x. \] (3.29)

For \( i = 0 \) and \( 0 < i < M_x - 1 \) at \( t > 0 \), letting that
\[ C_{i,1,j}^n = C_{0,j}^n - g_B(x) \Delta z. \] (3.30)

It follow that
\[ C_{0,j}^{n+1} = (\lambda_1 + \lambda_2) C_{0,j-1}^n + (1 - 2\lambda_1 - \tau_1 - \tau_2) C_{0,j}^n + (\lambda_1 - \lambda_2) C_{0,j+1}^n + Q \Delta t - (\tau_1 + \tau_2) g_B(x) \Delta z. \] (3.31)

For \( i = M_z \) and \( 0 < j < M_x - 1 \) at \( t > 0 \), letting that
\[ C_{M_z+1,j}^n = C_{M_z,j}^n + g_T(x) \Delta z. \] (3.32)

It follow that
\[ C_{M_z+1,j}^{n+1} = (\tau_1 + \tau_2) C_{M_z-1,j}^n + (1 - 2\lambda_1 - \tau_1 - \lambda_2) C_{M_z,j}^n + (\lambda_1 + \lambda_2) C_{M_z,j-1}^n + (\tau_1 - \tau_2) g_T(x) \Delta z. \] (3.33)

4 Numerical simulations

Suppose that the measurement of groundwater pollutant concentration \( C \) in a groundwater flow is considered in an underground area. The considered underground area has dimensions of 1.0 km of length and 0.5 km in depth, \( L_x = 1.0 \) km and \( L_z = 0.5 \) km, respectively. The simulations need to propose the measurement of the latitudinally averaged groundwater pollutant concentration in the considered area.

There is the landfill which is discharging leachate down to the considered underground area. The landfill is aligned with longitudinal distance 0.15 km, as shown in Figure 2. The landfill discharges the groundwater pollutant to the underground by \( C(x,0,t) = g_N(x) \) (kg/m²) for all 0.1 ≤ \( x \) ≤ 0.25.

Assume that the specific storage is 1 m⁻¹ and the hydraulic conductivity in \( x \)- and \( z \)-direction are 15 (m/day). There is no rate of change of hydraulic head on the left, the right, the bottom of the considered domain boundaries. There is no rate of change of hydraulic head on the top boundary. We also assume that the leachate which is flowing down to the underground has a pollutant concentration of 1.0 (kg/m³). There is no rate of change of pollutant concentration on the left, the right, the bottom domain boundaries. The related physical parameters are summarized in Table 1.

4.1 Simulation 4.1. Low leachate pollutant releasing rate with a low hydraulic head level.

If the proposed explicit finite difference techniques for the two-dimensional groundwater flow model Eqs.(3.6), (3.8), (3.10) and (3.12) are employed, we get the approximated groundwater flow velocity in the \( x \)- and \( z \)-direction in Table 4 and Figure 6. The approximated groundwater flow velocities are then plugged into the two-dimensional groundwater pollutant dispersion model. If the proposed explicit finite difference technique for the two-dimensional groundwater pollutant dispersion model Eqs.(3.25), (3.27), (3.29), (3.31) and (3.33) are employed, we get the approximated groundwater pollutant concentration as shown in Table 5 and Figures 7-8.

4.2 Simulation 4.2. Low leachate pollutant releasing rate with a high hydraulic head level.

If the proposed explicit finite difference techniques for the two-dimensional groundwater flow model Eqs.(3.6), (3.8), (3.10) and (3.12) are employed, we get an approximated hydraulic head as shown in Table 6 and Figures 9-10. If the proposed explicit finite difference technique for the groundwater flow velocity model Eqs.(3.15)-(3.16) are employed, we get the approximated groundwater flow velocity in the \( x \)- and \( z \)-direction in Table 7-8 and Figure 11. The approximated groundwater flow velocities are then plugged into the two-dimensional groundwater pollutant dispersion model. If the proposed explicit finite difference technique for the two-dimensional groundwater pollutant dispersion model Eqs.(3.25), (3.27), (3.29), (3.31) and (3.33) are employed, we get the approximated groundwater pollutant concentration as shown in Table 9 and Figures 12-13.

4.3 Simulation 4.3 Medium leachate pollutant releasing rate with a high hydraulic head level.

If the proposed explicit finite difference techniques for the two-dimensional groundwater flow model Eqs.(3.6), (3.8), (3.10) and (3.12) are employed, we get an approximated hydraulic head as shown in Table 10 and Figures 14-15. If the proposed explicit finite difference technique for the groundwater flow velocity model Eqs.(3.15)-(3.16) are employed, we get the approximated groundwater flow velocity in the \( x \)- and \( z \)-direction in Table 11-12 and Figure 16. The approximated groundwater flow velocities are then plugged into the two-dimensional groundwater pollutant dispersion model. If the proposed explicit finite difference technique for the two-dimensional groundwater pollutant dispersion model Eqs.(3.25), (3.27), (3.29), (3.31) and (3.33) are employed, we get the approximated groundwater pollutant concentration as shown in Table 13 and Figures 17-18.

4.4 Simulation 4.4. High leachate pollutant releasing rate with a high hydraulic head level.

If the proposed explicit finite difference techniques for the two-dimensional groundwater flow model Eqs.(3.6), (3.8),
If the proposed explicit finite difference technique for the groundwater flow velocity model Eqs.(3.15)-(3.16) are employed, we get the approximated groundwater flow velocity model Eqs.(3.15)-(3.16) are employed, we get the approximated groundwater flow velocity in the x- and z-direction in Table 15-16 and Figure 21. The approximated groundwater flow velocities are then plugged into the two-dimensional groundwater pollutant dispersion model. If the proposed explicit finite difference technique for the two-dimensional groundwater pollutant dispersion model Eqs.(3.25), (3.27), (3.29), (3.31) and (3.33) are employed, we get the approximated groundwater pollutant concentration as shown in Table 17 and Figures 22-23.

4.5 Simulation 4.5. Practical leachate pollutant releasing rate with a high hydraulic head level.

If the proposed explicit finite difference techniques for the two-dimensional groundwater flow model Eqs.(3.6), (3.8), (3.10) and (3.12) are employed, we get an approximated hydraulic head as shown in Table 18 and Figures 24-25. If the proposed explicit finite difference technique for the groundwater flow velocity model Eqs.(3.15)-(3.16) are employed, we get the approximated groundwater flow velocity in the x- and z-direction in Table 19-20 and Figure 26. The approximated groundwater flow velocities are then plugged into the two-dimensional groundwater pollutant dispersion model. If the proposed explicit finite difference technique for the two-dimensional groundwater pollutant dispersion model Eqs.(3.25), (3.27), (3.29), (3.31) and (3.33) are employed, we get the approximated groundwater pollutant concentration as shown in Table 21 and Figures 27-28.

5 Discussion

The hydraulic head can drive the groundwater flow from the higher hydraulic head level zone to the lower zone, as shown in Tables 2-4, 6-8, 10-12, and 14-16. The direction of groundwater is illustrated by their velocity field, as shown in Fig 4-6, 9-11, 14-16, and 19-20. In Simulation 4.1, a case of low leachate pollutant release rate from a landfill with a low-level hydraulic head is considered. If the level of the hydraulic head is increased fourfold, the overall groundwater quality becomes close to the last case, as shown in Simulation 4.2. On the other hand, if the level of leachate pollutant release rate is increased, the overall groundwater quality becomes as poor as the pollutant concentration at the considered landfill, as shown in Simulation 4.3. If the leachate releasing rate is poor or there is a high pollutant concentration, the overall groundwater quality becomes poor as well, as shown in Simulation 4.4. In Simulation 4.5, a case of practical leachate pollutant releasing rate is also tested by using numerical data interpolation f_L(x).

6 Conclusion

Three two-dimensional models of long-term contaminated groundwater pollutant measurement around a landfill are introduced. The first model is the two-dimensional transient groundwater flow model, which provides the hydraulic head. The second model is the groundwater flow velocity model, which provides the groundwater flow velocity in the x- and z-directions. The third model is the two-dimensional horizontal averaged contaminated groundwater dispersion model, which provides the groundwater pollutant concentration. A method to set up the initial condition and boundary conditions of the
proposed transient groundwater flow model is proposed. The computed hydraulic head is transformed to be the groundwater flow velocity by using the second model. The results from the second model will be inputted into the third model as field data. The groundwater pollutant concentration is obtained by the third model. The hydraulic head of the first model is approximated by an explicit finite difference method. An explicit finite difference technique is used to obtain the groundwater flow velocity of the second model. A forward time centered space finite difference technique is used to approximate the groundwater pollutant concentration. Long term groundwater quality around the landfill for 5, 10, 15, and 20 years are simulated. The groundwater quality is affected by the contaminated leachate pollutant release by the landfill. The proposed simulations show that the different levels of hydraulic head have a small effect on the overall groundwater quality level. Our proposed simulations found that the main groundwater quality factor is the leachate pollutant concentration around the landfill. Furthermore, a three-dimensional mathematical model for contaminated groundwater pollutant measurement should be introduced for a precise simulation.
