LITTLEWOOD-RICHARDSON SEMIGROUPS

ANDREI ZELEVINSKY

Abstract. This note is an extended abstract of my talk at the workshop on Representation Theory and Symmetric Functions, MSRI, April 14, 1997. We discuss the problem of finding an explicit description of the semigroup $LR_r$ of triples of partitions of length $\leq r$ such that the corresponding Littlewood-Richardson coefficient is non-zero. After discussing the history of the problem and previously known results, we suggest a new approach based on the “polyhedral” combinatorial expressions for the Littlewood-Richardson coefficients.

This note is an extended abstract of my talk at the workshop on Representation Theory and Symmetric Functions, MSRI, April 14, 1997. I thank the organizers (Sergey Fomin, Curtis Greene, Phil Hanlon and Sheila Sundaram) for bringing together a group of outstanding combinatorialists and for giving me a chance to bring to their attention some of the problems that I find very exciting and beautiful.

For $r \geq 1$, let

$$P_r = \{\lambda = (\lambda_1, \ldots, \lambda_r) \in \mathbb{Z}^r : \lambda_1 \geq \cdots \geq \lambda_r \geq 0\}$$

be the semigroup of partitions of length $\leq r$. Our main object of study will be the set

$$LR_r = \{(\lambda, \mu, \nu) : \lambda, \mu, \nu \in P_r, c_{\mu\nu}^{\lambda} > 0\},$$

where $c_{\mu\nu}^{\lambda}$ is the Littlewood-Richardson coefficient. Recall that $P_r$ is the set of highest weights of polynomial irreducible representations of $GL_r(\mathbb{C})$; if $V_\lambda$ is the irreducible representation of $GL_r(\mathbb{C})$ with highest weight $\lambda$ then $c_{\mu\nu}^{\lambda}$ is the multiplicity of $V_\lambda$ in $V_\mu \otimes V_\nu$. Equivalently, the $c_{\mu\nu}^{\lambda}$ are the structure constants of the algebra of symmetric polynomials in $r$ variables with respect to the basis of Schur polynomials. We call $LR_r$ the Littlewood-Richardson semigroup of order $r$; this name is justified by the following.

**Theorem 1.** $LR_r$ is a finitely generated subsemigroup of the additive semigroup $P_r^3 \subset \mathbb{Z}^{3r}$.

This is a special case of a much more general result well known to the experts in the invariant theory. A short proof (valid for any reductive group instead of $GL_r(\mathbb{C})$) can be found in [E]; A. Elashvili attributes this proof to M. Brion and F. Knop. The work is supported in part by NSF grant DMS-9625511; research at MSRI is supported in part by NSF grant DMS-9022140.
semigroup property also follows at once from “polyhedral” expressions for $c^λ_{\mu \nu}$ that will be discussed later.

**Problem A.** Describe $LR_r$ explicitly.

I have been interested in this problem for several years (e.g., in [BZ] the set \{ $\lambda : (\lambda, \delta, \delta) \in LR_r$ \} was determined, where $\delta = (r - 1, \ldots , 1, 0)$; this proves a special case of Kostant’s conjecture). Practically nothing is known about the list of indecomposable generators of $LR_r$ for general $r$. We will discuss the “dual” approach, namely we would like to describe the facets of the polyhedral convex cone $LR_r^R \subset R^{3r}$ generated by $LR_r$. A remarkable progress in this direction was recently made by A. Klyachko in [K]. Before discussing his results, let us note that $c^λ_{\mu \nu}$ is given by the classical Littlewood-Richardson rule (see e.g., [M]), which in principle makes Problem A purely combinatorial. In particular, the Littlewood-Richardson rule (or just the definition) readily implies the following properties of $LR_r$.

**Homogeneity.** $|\lambda| = |\mu| + |\nu|$ for $(\lambda, \mu, \nu) \in LR_r$, where $|\lambda| = \lambda_1 + \cdots + \lambda_r$.

**Stability.** $LR_{r+1} \cap Z^{3r} = LR_r$, where $Z^{3r} = \{(\lambda, \mu, \nu) \in Z^{3(r+1)} : \lambda_{r+1} = \mu_{r+1} = \nu_{r+1} = 0\}$. Even stronger, we have $LR_{r+1} \cap Z^{3r+2} = LR_r$, where $Z^{3r+2} = \{(\lambda, \mu, \nu) \in Z^{3(r+1)} : \lambda_{r+1} = 0\}$.

Littlewood-Richardson semigroups appear naturally in several other contexts:

1. Hall algebra, extensions of abelian $p$-groups: see [M].
2. Schubert calculus on Grassmannians: see [F].
3. Polynomial matrices and their invariant factors: see [T].
4. Eigenvalues of sums of Hermitian matrices.

Let us discuss the last item in more detail. For a Hermitian matrix $A$ of order $r$, let $\lambda(A)$ denote the sequence of eigenvalues of $A$ arranged in a weakly decreasing order (recall that $A$ is Hermitian if $A^* = A$, and such a matrix always has real eigenvalues). Let $HE_r$ denote the set of triples $(\lambda, \mu, \nu) \in R^{3r}$ such that $\lambda = \lambda(A + B), \mu = \lambda(A)$, and $\nu = \lambda(B)$ for some Hermitian matrices $A$ and $B$ of order $r$. The following counterpart of Theorem 1 for $HE_r$ is highly non-trivial.

**Theorem 2.** $HE_r$ is a polyhedral convex cone in $R^{3r}$.

**Problem B.** Describe $HE_r$ explicitly.

Problems A and B are closely related to each other. They have a long history. Problem B was probably first posed by I.M. Gelfand in the late 40’s (eigenvalues of the sum of two Hermitian matrices were studied already by H. Weyl in 1912, but I believe I.M Gelfand was the first who suggested to study the cone $HE_r$ as a whole rather than concentrate on individual eigenvalues). A solution was announced by V.B. Lidskii in [L1], but the details of the proof were never published.
and I.M. Gelfand in [BG] discussed the relationships between Problems A and B; in particular, they suggested the following remarkable equality:

\[ HE_r \cap P^3_r = LR_r. \]  

(1)

A. Horn in [H] solved Problem B for \( r \leq 4 \) and conjectured a general answer. To formulate his conjecture we need some terminology. Let \([1, r] = \{1, 2, \ldots, r\}\). For a subset \(I = \{i_1 < i_2 < \cdots < i_s\} \subset [1, r]\), we denote by \(\rho(I) \subset P^s_r\) the partition \(\rho(I) = (i_s - s, \ldots, i_2 - 2, i_1 - 1)\).

**Horn’s Conjecture.** Let \(\lambda, \mu, \nu\) be vectors in \(\mathbb{R}^r\) with weakly decreasing components. Then \((\lambda, \mu, \nu) \in HE_r\) if and only if \(|\lambda| = |\mu| + |\nu|\) and \(|\lambda|_I \leq |\mu|_J + |\nu|_K\) for all \(HE\)-consistent triples \((I, J, K)\) in \([1, r]\).

The proofs of both Horn’s Conjecture and (1) were announced by B.V. Lidskii (not to be confused with the author of [L1]) in [L2]. Unfortunately, as in the case of [L1], the detailed proofs of the results in [L2] never appeared. This justifies A. Klyachko’s claim in [K] that even Theorem 2 has not been proved before.

Let us now discuss the results in [K]. First of all, A. Klyachko proves Theorem 2; moreover, he gives the following description of the facets of \(HE_r\), which is very close (but not totally equivalent) to Horn’s Conjecture. Modifying the definition of \(HE\)-consistent triples, we will call a triple of subsets \(I, J, K \subset [1, r]\) \(LR\)-consistent if they have the same cardinality \(s\), and \((\rho(I), \rho(J), \rho(K)) \in LR_s\).

**Theorem 3.** Horn’s conjecture becomes true if \(HE\)-consistency in the formulation is replaced by \(LR\)-consistency. Moreover, the inequalities \(|\lambda|_I \leq |\mu|_J + |\nu|_K\) for all \(LR\)-consistent triples \((I, J, K)\) in \([1, r]\) are independent, i.e., they correspond to facets of the polyhedral convex cone \(HE_r\).

A. Klyachko also proves the following weaker version of (1). Let \(LR^Q_r\) be the set of all linear combinations of triples in \(LR_r\) with positive rational coefficients; equivalently, \(LR^Q_r = \cup_{N \geq 1} \frac{1}{N} LR_r\).

**Theorem 4.** \(HE_r \cap Q^3_r = LR^Q_r\).

Theorems 3 and 4 appear in [K] as a by-product of the study of stability criteria for toric vector bundles on the projective plane \(P^2\). In view of these theorems, the equality (1) and Horn’s Conjecture would follow from the affirmative answer to the following

**Saturation Problem.** Is it true that \(LR^Q_r \cap P^3_r = LR_r\)?
In other words, does the fact that \( c_{\mu \nu}^{\lambda} \geq 0 \) for some \( N \geq 1 \) imply that \( c_{\mu \nu}^{\lambda} > 0 \)?

This is true and easy to check for \( r \leq 4 \). On the other hand, an obvious analogue of the problem for type \( B \) has negative answer (as pointed out to me by M. Brion, counterexamples can be found in [E]).

**Examples.** Here are the linear inequalities corresponding to \( LR \)-consistent triples for \( r \leq 3 \); combined with the conditions \( \lambda_1 \geq \cdots \geq \lambda_r, \mu_1 \geq \cdots \geq \mu_r, \nu_1 \geq \cdots \geq \nu_r, \) and \( |\lambda| = |\mu| + |\nu| \), they provide a description of the cone \( HE_r \).

- \( r = 1 \): no inequalities;
- \( r = 2 \): \( \lambda_1 \leq \mu_1 + \nu_1, \lambda_2 \leq \min (\mu_1 + \nu_2, \mu_2 + \nu_1) \);
- \( r = 3 \): \( \lambda_1 \leq \mu_1 + \nu_1, \lambda_2 \leq \min (\mu_1 + \nu_2, \mu_2 + \nu_1, \mu_3 + \nu_1), \lambda_1 + \lambda_2 \leq \min (\mu_1 + \nu_3 + \nu_2, \mu_2 + \nu_3, \mu_3 + \nu_1 + \nu_2), \lambda_2 + \lambda_3 \leq \min (\mu_1 + \nu_2 + \nu_3, \mu_2 + \nu_3, \mu_3 + \nu_1 + \nu_2) \). For instance, the inequality \( \lambda_2 + \lambda_3 \leq \mu_1 + \mu_3 + \nu_1 + \nu_3 \) corresponds to the triple \( (I, J, K) = ([0, 1, 0], [0, 1, 0], [1, 0, 0]) \), which is \( LR \)-consistent because the triple of partitions \( (\rho(I), \rho(J), \rho(K)) = ((1, 1, 1), (1, 0, 1), (0, 1, 0)) \) obviously belongs to \( LR_2 \).

Assuming the affirmative answer in the Saturation Problem, Theorem 3 provides a recursive procedure for describing the semigroup \( LR_r \). Although quite elegant, this procedure is not very explicit from combinatorial point of view. Thus, we would like to formulate the following

**Problem C.** Find a non-recursive description of \( LR_r \).

Equivalently, Problem C asks for a non-recursive description of \( LR \)-consistent triples. We would like to suggest an elementary combinatorial approach to this problem based on the “polyhedral” expressions for the coefficients \( c_{\mu \nu}^{\lambda} \) given in [BZ]. To present such an expression, it will be convenient to modify Littlewood-Richardson coefficients as follows. We will consider triples \( (\bar{\lambda}, \bar{\mu}, \bar{\nu}) \) of dominant integral weights for the group \( SL_r \). Let \( V_\lambda \) be the irreducible \( SL_r \)-module with highest weight \( \lambda \), and let \( c_{\bar{\lambda} \bar{\mu} \bar{\nu}} \) denote the dimension of the space of \( SL_r \)-invariants in the triple tensor product \( V_\lambda \otimes V_\mu \otimes V_\nu \). The relationship between the \( c_{\lambda \mu \nu} \) and the Littlewood-Richardson coefficients is as follows. We will write each of the weights \( \bar{\lambda}, \bar{\mu}, \bar{\nu} \) as a nonnegative integer linear combination of fundamental weights \( \omega_1, \omega_2, \ldots, \omega_{r-1} \) (in the standard numeration):

\[
\bar{\lambda} = l_1 \omega_1 + \cdots + l_{r-1} \omega_{r-1}, \quad \bar{\mu} = m_1 \omega_1 + \cdots + m_{r-1} \omega_{r-1}, \quad \bar{\nu} = n_1 \omega_1 + \cdots + n_{r-1} \omega_{r-1}. \tag{2}
\]

The definitions readily imply that if \( \lambda, \mu, \nu \in P_r \) are such that \( |\lambda| = |\mu| + |\nu| \) then \( c_{\lambda \mu \nu} = c_{\bar{\lambda} \bar{\mu} \bar{\nu}} \), where the coordinates \( l_s, m_s \) and \( n_s \) in (2) are given by

\[
l_s = \lambda_{r-s} - \lambda_{r-s+1}, \quad m_s = \mu_{s} - \mu_{s+1}, \quad n_s = \nu_{s} - \nu_{s+1}. \tag{3}
\]

Thus, the knowledge of \( LR_r \) is equivalent to the knowledge of the semigroup

\[
\overline{LR}_r = \{ (\bar{\lambda}, \bar{\mu}, \bar{\nu}) \in \mathbb{Z}_{\geq 0}^{3(r-1)} : c_{\bar{\lambda} \bar{\mu} \bar{\nu}} > 0 \}.
\]
Passing from $LR_r$ to $\overline{LR}_r$ has two important advantages. First, the coefficients $c_{\bar{\lambda}\bar{\mu}\bar{\nu}}$ are more symmetric than the original Littlewood-Richardson coefficients: they are invariant under the 12-element group generated by all permutations of three weights $\bar{\lambda}, \bar{\mu}$ and $\bar{\nu}$, together with the transformation replacing each of these weights with its dual (i.e., sending $(l_s, m_s, n_s)$ to $(l_{r-s}, m_{r-s}, n_{r-s})$). Second, the dimension of the ambient space reduces by 2, from $3r - 1$ to $3(r - 1)$. On the other hand, $\overline{LR}_r$ has at least one potential disadvantage: the condition $|\lambda| = |\mu| + |\nu|$ is replaced by a more complicated condition that $\sum_s s(l_s + m_s + n_s)$ is divisible by $r$ (in more invariant terms, this means that $\bar{\lambda} + \bar{\mu} + \bar{\nu}$ must be a radical weight, i.e., belongs to the root lattice).

To illustrate both phenomena, one can compare the description of $LR_2$ given above with the following description of $\overline{LR}_2$ which is equivalent to the classical Clebsch-Gordan rule: $\overline{LR}_2$ consists of triples of nonnegative integers $(l_1, m_1, n_1)$ satisfying the triangle inequality and such that $l_1 + m_1 + n_1$ is even.

Let us now give a combinatorial expression for $c_{\bar{\lambda}\bar{\mu}\bar{\nu}}$ (this is one of several such expressions found in [BZ]). Consider a triangle in $R^2$, and subdivide it into small triangles by dividing each side into $r$ equal parts and joining the points of the subdivision by the line segments parallel to the sides of our triangle. Let $Y_r$ denote the set of all vertices of the small triangles, with the exception of the three vertices of the original triangle. Introducing barycentric coordinates, we identify $Y_r$ with the set of integer triples $(i, j, k)$ such that $0 \leq i, j, k < r$ and $i + j + k = r$. Let $Z^{Y_r}$ be the set of integer families $(y_{ijk})$ indexed by $Y_r$; we think of $y \in Z^{Y_r}$ as an integer “matrix” with $Y_r$ as the set of “matrix positions.” To every $y \in Z^{Y_r}$ we associate the partial line sums

$$l_{ts}(y) = \sum_{j=t}^s y_{r-s,j,s-j}, \quad m_{ts}(y) = \sum_{k=t}^s y_{s-k,r-s,k}, \quad n_{ts}(y) = \sum_{i=t}^s y_{i,s-i,r-s}, \quad (4)$$

where $0 \leq t \leq s \leq r$. We call these linear forms on $R^{Y_r}$ tails, and we say that $y \in R^{Y_r}$ is tail-positive if all tails of $y$ are $\geq 0$. We also say that a linear form on $R^{Y_r}$ is tail-positive if it is a nonnegative linear combination of tails.

**Theorem 5.** For any triple $(\bar{\lambda}, \bar{\mu}, \bar{\nu})$ as in (2), the coefficient $c_{\bar{\lambda}\bar{\mu}\bar{\nu}}$ is equal to the number of tail-positive $y \in Z^{Y_r}$ with prescribed values of line sums

$$l_{0s}(y) = l_s, \quad m_{0s}(y) = m_s, \quad n_{0s}(y) = n_s \quad (1 \leq s \leq r - 1). \quad (5)$$

In other words, let $T_r \subset Z^{Y_r}$ denote the semigroup of tail-positive elements, and let $\sigma : Z^{Y_r} \rightarrow Z^{3(r-1)}$ be the projection given by (5). Then Theorem 5 says that

$$\sigma(T_r) = \overline{LR}_r. \quad (6)$$

In particular, this implies at once that $\overline{LR}_r$ (and hence $LR_r$) is a semigroup. Furthermore, Theorem 5 implies the following description of the convex cone $\overline{LR}_r^R$ generated by $\overline{LR}_r$. 

LITTLEWOOD-RICHARDSON SEMIGROUPS

5
Corollary 6. A linear form $f$ on $\mathbb{R}^{3(r-1)}$ takes nonnegative values on $LR_r^R$ if and only if the form $f \circ \sigma$ on $R^Y_r$ is tail-positive.

Returning to the Littlewood-Richardson semigroup $LR_r$, we have the projection $\partial : LR_r \to LR_r^R$ given by (3). This projection extends by linearity to a projection $\partial : \mathbb{R}^{3r-1} \to \mathbb{R}^{3(r-1)}$, where $\mathbb{R}^{3r-1}$ is the subspace of triples $(\lambda, \mu, \nu) \in \mathbb{R}^{3r}$ satisfying $|\lambda| = |\mu| + |\nu|$. It is clear that the cone $LR_r^R \subset \mathbb{R}^{3r-1}$ is given by the linear inequalities $f \circ \partial \geq 0$ for all linear forms $f$ as in Corollary 6. This suggests the following strategy for determining the set of $LR$-consistent triples. Take a triple of subsets $(I, J, K)$ in $[1, r]$ of the same cardinality $s$, consider the corresponding linear form $|\mu|_J + |\nu|_K - |\lambda|_I$ on $\mathbb{R}^{3r-1}$, write this form as $f \circ \partial$, and compute the form $f \circ \sigma$ on $R^Y_r$. A straightforward calculation gives

$$ (f \circ \sigma)(y) = \sum_{(i,j,k) \in Y_r} \left( \#(I_i) - \#(J_{r-j}) - \#(K_{r-k}) \right) y_{ijk}, \quad (7) $$

where $\#(I_i)$ stands for the number of elements of $I$ which are $> i$. Taking into account Theorem 3, we obtain the following criterion for $LR$-consistency.

**Theorem 7.** A triple of subsets $(I, J, K)$ of the same cardinality $s$ in $[1, r]$ is $LR$-consistent if and only if $|\rho(I)| = |\rho(J)| + |\rho(K)|$ and the form in (7) is tail-positive.

In particular, since every tail-positive linear form is obviously a nonnegative linear combination of the $y_{ijk}$, we obtain the following necessary condition for $LR$-consistency.

**Corollary 8.** If a triple of subsets $(I, J, K)$ in $[1, r]$ is $LR$-consistent then

$$ \#(I_i) \geq \#(J_{r-j}) + \#(K_{r-k}) $$

for all $(i, j, k) \in Y_r$.

It would be interesting to deduce this corollary directly from the Littlewood-Richardson rule. One can show that (8) is not sufficient for $LR$-consistency. In fact, Theorem 7 can be used to produce other necessary conditions for $LR$-consistency. One can hope to solve Problem C by generating a system of necessary and sufficient conditions for $LR$-consistency using this method.
