Autopsy-certified maternal mortality at Ile-Ife, Nigeria

Aim: Maternal mortality is a major health problem, especially in Nigeria, where accurate autopsy-based data on the prevalent causes are not readily available. The aim of this study was therefore to accurately determine the causes of maternal death as seen in a tertiary health facility in Nigeria.

Materials and methods: This was a descriptive, retrospective review of the postmortem autopsy findings from cases of maternal death at the Obafemi Awolowo University Teaching Hospitals Complex, Ile-Ife, Nigeria over a 5-year period. Analyses were performed for differences in proportions using PEPI computer programs for epidemiologists (P is significant at <0.05).

Results: A total of 84 cases of maternal deaths were used for the study. Approximately 71.4% of the maternal deaths were due to direct causes and 28.6% were due to indirect causes. The mean age at the time of death was 27.9 ± 7.5 years. Overall, the three leading causes of death were obstetric hemorrhage (30.9%), complications of abortion (23.8%), and nongenital (nonobstetric) infections (14.2%). Of the direct causes of maternal death, obstetric hemorrhage (43.3%) was the leading cause, with postpartum hemorrhage accounting for most (65.0%) of such deaths; other causes included complications of unsafe induced abortion (33.3%) and of labor (11.7%). Of the indirect causes, nongenital infections (50.0%), anemia (25.0%), and preexisting hypertension (20.8%) accounted for the majority of the maternal deaths. There was disparity between the clinical and autopsy diagnoses in 34 of the 84 cases (38.1%).

Conclusion: The leading causes of maternal death in this study are similar to those in other developing countries. Autopsy is an invaluable tool in accurately determining the cause of maternal death.

Keywords: autopsy, causes, maternal mortality, Nigeria

Introduction

Approximately 250,000 African women are said to die yearly during pregnancy, delivery, or the puerperium. Maternal deaths in Nigeria contribute significantly to this number. In fact, data from the United Nations and the World Bank have identified Nigeria as one of the worst places in the world for a woman to give birth, with about 59,000 women dying every year due to pregnancy-related complications. The average maternal mortality rate in Nigeria is estimated to be about 704 deaths per 100,000 live births, although this number ranges from about 165 deaths per 100,000 live births in the southwest region to 1,549 deaths per 100,000 live births in the northeastern subregions of the country. These unacceptably high rates have prompted the Nigerian government to join the international community in adopting

the Millennium Development Goal of reducing maternal mortality rate by 75% by the year 2015. Although many policies and programs have been put in place over the years to achieve this goal, the results have been less than optimal, possibly because they have been driven by limited scientific information, most of which has been obtained from clinical records and verbal autopsies.\(^3\)\(^-\)\(^5\)

The role of the autopsy as a tool in the prevention and reduction of maternal deaths has been well-documented, especially in developed countries where maternal mortality rates are now so low that perinatal death rates are more appropriately used as an index of the state of the health system. In such countries, thorough postmortem examinations are regularly conducted as part of confidential inquiries into maternal deaths, with reports being published at regular intervals.\(^6\)

Information provided by medical autopsies is known to increase the accuracy of cause of death reports, even in cases where the cause of death can be wholly based on clinical evaluation.\(^7\)\(^-\)\(^10\) Maternal autopsies are thus required for accurate death certification, determination of the underlying causes of death, and establishment of maternal mortality rates.\(^9\) These are invaluable tools for reducing and preventing maternal deaths.

In accordance with recommendations from the Safe Motherhood Conference held in Abuja in 1990, the Federal Government of Nigeria has directed that confidential inquiries be conducted for maternal deaths in Nigeria (with the autopsy as a pivotal tool) and that regular reports be made to the Federal Ministry of Health.\(^5\) This has led to an increase in the demand for maternal autopsies at the Obafemi Awolowo University Teaching Hospitals Complex, Ile-Ife, Nigeria (OAUTHC), a referral tertiary health care facility located in the southwestern region of Nigeria.

The aim of this study was to review the autopsy findings from postmortem examinations conducted on cases of maternal mortality at the OAUTHC tertiary health facility, in order to accurately determine the causes of maternal death prevalent in our environment.

**Materials and methods**

This was a descriptive retrospective study of the autopsy findings from postmortem examinations conducted on cases of maternal mortality in the Department of Morbid Anatomy and Forensic Medicine, OAUTHC, between January 1, 2005 and December 31, 2009. The cases selected for the study were those that satisfied the World Health Organization definition of maternal death.\(^11\) Data for this study were obtained from the departmental autopsy records and register as well as from the patient’s clinical notes. Information such as the patient’s age, parity, occupation, gestational age, mode of delivery, clinical diagnosis, and anatomical diagnosis was extracted. At the OAUTHC, all cases of pregnancy-related deaths are referred to the Department of Morbid Anatomy and Histopathology for a full postmortem autopsy (which includes both macroscopic examination and histologic evaluation of all viscera, using standardized protocols), the results of which are relayed to the Federal Ministry of Health as part of a confidential inquiry into maternal deaths.

All cases of maternal death were classified as having either direct or indirect causes, on the basis of the specific anatomical diagnosis. The specific anatomical diagnoses with respect to direct maternal deaths were further classified as: 1) obstetric hemorrhage (including abruptio placentae, placenta previa, uterine atony, ruptured ectopic pregnancy, retained products of conception, uterine rupture, etc); 2) complications of labor (including puerperal sepsis, aspiration pneumonitis); or 3) complications of unsafe abortion (including sepsis, uterine perforation, hypovolemic shock). Indirect causes of maternal deaths were classified as anemia, neoplasms, preexisting hypertension, and nongenital infections (including pyogenic and tuberculous meningitis, pulmonary tuberculosis, broncho/lobar pneumonia). In cases where the clinical diagnosis was usually sufficiently accurate (eg, eclampsia), specific autopsy findings were sought to corroborate the clinical diagnosis.

The patients were also grouped into different parity groups: never given birth (Nullipara); given birth one time (Para 1); given birth two, three, or four times (Para 2–4); given birth more than four times (>Para 4). These parity groups were compared with the various causes of maternal death.

The data obtained was analyzed using Computer Programs for Epidemiologists (PEPI).\(^12\) Univariate analysis was carried out and the causes of maternal deaths were presented in frequencies and percentages. Chi-square analysis was performed with the \(P\)-value set at 0.05.

Ethical approval for this study was obtained from the OAUTHC Ethics and Research Committee.

**Results**

During the 5-year period under review, a total of 1,969 autopsies were performed in the OAUTHC Department of Morbid Anatomy and Forensic Medicine. A total of 128 maternal deaths occurred during 7,472 live births during this period, resulting in a maternal mortality rate of 1,713 per 100,000 live births. Autopsies were conducted on 102 (5.2% of all

undergone uterine rupture (17.6%), complications of preexisting hypertension (14.7%), postabortion sepsis (14.7%), postpartum hemorrhage (8.8%), puerperal sepsis (5.8%), anemic heart failure (5.8%), and abruptio placenta (2.9%).

Discussion

Direct (obstetric) causes accounted for the vast majority (71.4%) of maternal deaths in this autopsy-based study, with obstetric hemorrhage accounting for a significant number of cases. In fact, obstetric hemorrhage was the single most frequent cause of maternal death overall. Also worthy of note is the fact that most postpartum hemorraghes were due to uterine atony, especially in high-risk women who belonged to the high-parity group. These women were also more likely to be in the older age groups. These findings are in agreement with various studies conducted in other parts of Nigeria and in other developing countries. Also noteworthy is the high proportion (23.8%) of complications resulting from unsafe induced abortion.

Complications of unsafe abortion remain a major cause of maternal mortality in developing countries, due to the fact that abortion is illegal in most of such countries, including Nigeria. The types of complications arising from these unsafe (and illegal) abortions (septicemia, severe hemorrhage, uterine perforation) suggest that these procedures were performed either by unqualified personnel or carried out in inappropriate care centers. This is buttressed by the fact that most of the affected women in this study were young (<25 years of age) and unmarried dependents.

Overall, the results of this study suggest that infectious diseases contribute significantly to maternal mortality, constituting 33.3% of cases. A significant proportion of these were due to infections not directly related to the pregnancy (nongenital infections). These nongenital infections accounted for 50.0% of all obstetric or indirect maternal deaths (and 14.2% of all maternal deaths) and included easily

| (n=17)                          | Ruptured uterus              | 2 (11.8) |
|                                 | Retained placenta            | 2 (11.8) |
| Complications of abortion       | Septicemia                   | 11 (55.0) |
| (n=20)                          | Hemorrhage                   | 5 (25.0) |
|                                 | Uterine perforation          | 4 (20.0) |
| Nongenital infections           | Purulent meningitis          | 5 (41.7) |
| (n=12)                          | Pulmonary tuberculosis       | 3 (25.0) |
|                                 | Pneumonia                    | 3 (25.0) |
|                                 | Tuberculous meningitis       | 1 (8.3) |
| Complications from preexisting hypertension | Malignant hypertension | 2 (40.0) |
| (n=5)                           | Left ventricular failure     | 2 (40.0) |
|                                 | Intracranial hemorrhage      | 1 (20.0) |
treatable conditions, some of which are typically associated with low case-fatality rates. The prompt diagnosis and treatment of infectious diseases during pregnancy may thus have a significant impact on reducing maternal mortality in this environment.

Direct or obstetric causes of maternal deaths, unlike the indirect causes, are well-known to be associated with increasing maternal age, parity, and the stage of the pregnancy, as these factors have direct physiological effects on the outcomes of the pregnancies.\(^3,6,19,20\) These facts were corroborated by this study, which showed that complications from unsafe abortions and pregnancy-induced hypertension were more common in the younger age group, whereas obstetric hemorrhages were more common in women older than 25 years of age and in the third trimester. Although complications from unsafe abortions and ectopic pregnancy were more common in the first and second trimesters, complications associated with pregnancy-induced hypertension were more likely in the later stages of pregnancy.

Poverty and poor education are well-known to contribute significantly to maternal mortality. In this study, 70.0% of maternal deaths occurred among the unskilled, unemployed, and student populations.\(^{21,22}\) This may explain why many of these women did not receive any proper form of antenatal care, the lack of which is well-known to contribute significantly to maternal mortality. Our study showed that 67.0% of the women did not receive antenatal care and were seen for the first time when they presented with various complications.\(^3,23\)

In the developing world, where maternal mortality rates are highest, the leading causes of death are well-known. Nevertheless, complex disease processes with uncertain pathogenesis and clinical presentations can pose a problem for accurate death certification, even in developed countries. These may adversely affect the accuracy of the relevant data on maternal mortality, with the attendant consequences on efforts geared at reducing it. Thus, maternal autopsies are required for accurate death certification and determination of the actual underlying causes of death.\(^6\) Our study showed discrepancies between the clinical and autopsy-based diagnoses in 38.1% of cases. These discrepancies cut across all of the various causes of maternal death. This greatly underscores the importance of maternal autopsies in making accurate diagnoses with the attendant consequences for the prevention and reduction of maternal deaths, which have been well-documented in many developed countries.\(^6\)

The maternal mortality rate observed in this study (1,713 deaths per 100,000 live births) is much higher than the Nigerian national average, which ranges between 165 deaths per 100,000 live births in the southwest region.
to 1,549 deaths per 100,000 live births in the northeastern subregions of the country. Similarly, results from this study may not accurately reflect the entire community, because the study center (OAUTHC) is at the highest referral level for the country. Nevertheless, this study underscores the poor state of Nigeria’s health care delivery system. Efforts should therefore be mobilized to ensure great improvement in the nearest future.
