Sharp, strong and unique minimizers for low complexity robust recovery

Jalal Fadili* Tran T. A. Nghia† Trinh T. T. Tran‡

Abstract

In this paper, we show the important roles of sharp minima and strong minima for robust recovery. We also obtain several characterizations of sharp minima for convex regularized optimization problems. Our characterizations are quantitative and verifiable especially for the case of decomposable norm regularized problems including sparsity, group-sparsity, and low-rank convex problems. For group-sparsity optimization problems, we show that a unique solution is a strong solution and obtain quantitative characterizations for solution uniqueness.

1 Introduction

1.1 Problem statement

Inverse problems and regularization theory is a central theme in various areas of engineering and science. A typical case is where one observes a vector \( y_0 \in \mathbb{R}^m \) of linear measurements according to

\[
y_0 = \Phi x_0
\]  

(1.1)

where \( \Phi \in \mathbb{R}^{m \times n} \) is known, and is typically an idealization of the sensing mechanism in signal/imaging science applications, or the design matrix in a parametric statistical regression problem. The vector \( x_0 \in \mathbb{R}^n \) is the unknown quantity of interest.

Solving the inverse problem associated to the linear forward model (1.1) amounts to recovering \( x_0 \), either exactly or to a good approximation, knowing \( y_0 \) and \( \Phi \). This is however a quite challenging task especially when the linear system (1.1) is underdetermined with \( m < n \). In fact, even when \( m = n \), \( \Phi \) is in general ill-conditioned or even singular. This entails that the linear inverse problem is in general ill-posed.

In order to bring back the problem to the land of well-posedness, it is necessary to restrict the inversion process to a well-chosen subset of \( \mathbb{R}^n \) containing the plausible solutions including \( x_0 \). This can be achieved by adopting a variational framework and solving the following optimization problem

\[
\min_{x \in \mathbb{R}^n} J(x) \quad \text{subject to} \quad \Phi x = y_0,
\]  

(1.2)

where \( J \) is function which is bounded from below (wlog non-negative). The function \( J \), known as a regularizer, is designed in such way that it is the smallest on the sought-after solutions. Popular example in signal/image processing and machine learning is the \( \ell_1 \) norm to promote sparsity, the \( \ell_1/\ell_2 \) norm to promote group sparsity, analysis sparsity seminorm (i.e., \( J = J_0 \circ D^* \), \( D^* : \mathbb{R}^n \to \mathbb{R}^p \) is linear and \( J_0 \) is the \( \ell_1 \) or \( \ell_1/\ell_2 \) norm); see [6, 9, 12, 21, 29, 33, 35, 41, 43] to cite a few. Another popular example is the nuclear norm, i.e., the \( \ell_1 \) norm of the singular values of a matrix, to recover low-rank matrices [10, 8]. These prototypical cases are included in the class of decomposable norms [26, 7, 14] that covers a wide range of optimization-based recovery problems in different areas of data science.

When the observation is subject to errors, the system (1.1) is modified to

\[
y = \Phi x_0 + \omega
\]  

(1.3)

where \( \omega \) accounts either for noise and/or modeling errors. The errors can be either deterministic (in this case, one typically assumes to know some bound on \( \|\omega\| \)) or random (in which case its distribution is assumed to be known). Throughout, \( \omega \) will be assumed deterministic with \( \|\omega\| \leq \delta \), with \( \delta > 0 \) known.
To recover $x_0$ from (1.3), one solves the noise-aware form (aka Mozorov regularization in the inverse problems literature)

$$\min_{x \in \mathbb{R}^n} J(x) \quad \text{subject to} \quad \|y - \Phi x\| \leq \delta$$

(1.4)

or its penalized/Lagrangian form (aka Tikhonov regularization in the inverse problems literature)

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} \|\Phi x - y\|^2 + \mu J(x).$$

(1.5)

with regularization parameter $\mu > 0$. It is well-known that (1.4) and (1.5) are formally equivalent in the sense that there exists a bijection between $\delta$ and $\mu$ such that the both problems share the same set of solutions.

We say that robust recovery occurs when solutions to (1.4) or (1.5) are close enough to the original signal $x_0$ as long as $\mu$ is appropriately chosen (as a function of the noise level $\delta$). For $\ell_1$-regularized optimization problem, a significant result was achieved in [19, Theorem 4.7], which shows that when $\mu$ is proportional to $\delta$, the error between any solution of problem (1.5) to $x_0$ is $O(\delta)$ if and only if $x_0$ is the unique solution to (1.2). The structure of the $\ell_1$ norm plays a crucial role in their result. Sufficient (but not necessary in general) conditions for robust recovery with a linear convergence rate have been proposed for general class of regularizers by solving either (1.4) or (1.5); see [10, 14, 39, 42, 36] and references therein. For instance [10] and [36] provide a sufficient condition via the geometric notion of descent cone for robust recovery with linear rate by solving (1.4) (but not (1.5)). Injectivity of $\Phi$ on the descent cone turns out to be a sufficient and necessary condition for solution uniqueness of (1.2). However, solution uniqueness is not enough to guarantee robust recovery with linear rate for general regularizers.

In fact, we observe that [10] needs $x_0$ to be a sharp solution to problem (1.2). A sharp minimum, introduced by Crome and Polyak [11, 27, 28], is a point around which the objective value has a first-order growth (see Section 2 for a rigorous definition and discussion). It is certainly sufficient for solution uniqueness and indeed is called strong uniqueness in [11]. In the case of polyhedral problems, e.g., problem (1.2) with $\ell_1$ or $\ell_{\infty}$ norms, solution uniqueness is equivalent to sharp minima. This is the key reason why [19] only needs solution uniqueness for robust recovery with linear rate. In the optimization community, sharp minima is well-known for its essence to finite convergence of the proximal point algorithms; see, e.g., [28, 31].

Sharp minima is actually hidden in both exact recovery (by solving (1.2)) and robust recovery. As we will show later, sharpness is closely related to many other results on exact and robust recovery, for instance those involving conditions based on non-degenerate dual certificates (aka Nondegenerate Source Condition) and restricted injectivity of $\Phi$, or the Null Space Property and its variants; see [12, 9, 37, 16, 38, 8, 6, 19, 15, 41, 14, 7, 41, 39, 42, 44]. When $\Phi$ is drawn from an appropriate random ensemble, existing sample complexity bounds (i.e., a lower-bound on $m$ depending on the “intrinsic” dimension of the model subspace containing $x_0$ and logarithmically on $n$) rely on verifying the afore-mentioned conditions with high probability on $\Phi$; see [15, 42, 36] for comprehensive reviews. For Gaussian measurements, sample complexity bounds for exact recovery are provided in terms of the Gaussian width in [10] and the statistical dimension in [1], and the latter has been shown to precise predictions about the quantitative aspects of the phase transition for exact recovery from Gaussian measurements.

Another popular notion in optimization [5, 32] is that of strong minima, which is a sufficient condition for solution uniqueness. It is also used implicitly in many results on robust recovery.

---

1This justifies the conventional terminology “linear convergence rate”.
A strong minimum is a point around which the objective value has a quadratic (or second-order) growth. Strong minima are certainly weaker than sharp minima. In the $\ell_1$ case, we observe that the cost function in (1.5) belongs to the bigger class of convex piecewise linear-quadratic functions [32]. A unique solution to this function is also a strong solution. This simple observation was used recently in [4] to obtain some characterizations for solution uniqueness to (1.5) for the case of the Lasso problem. Necessary and sufficient conditions for solution uniqueness to (1.5) where $J$ is piecewise linear are also studied in [17, 24, 44].

1.2 Contributions and relation to prior work

The chief goal of this paper is to show the intricate and important roles of sharp minima and strong minima in robust recovery. Our main contributions are as follows.

- As discussed above, solution uniqueness and sharp minima play a pivotal role for robust recovery with linear rate. However, except the case where the regularizer $J$ is merely polyhedral, a unique solution may not be sharp. For example, as we will show in our Section 5, a unique solution to the group-sparsity problem (1.2) is always a strong minimum but not a sharp one. The natural question is therefore whether strong minima could also lead to some meaningful results for robust recovery. Section 3 answers this question positively without even needing convexity of $J$, unlike the previous work of [39, 42] which showed that a sharp minimizer implicitly guarantees robust recovery with linear rate, but convexity was essential there. We show that if $x_0$ is a strong solution to (1.2), then we have robust recovery by solving (1.4) or (1.5) with a convergence rate $O(\sqrt{\delta})$ (Theorem 3.12). This rate can be improved to the linear rate $O(\delta)$ when $J = \| \cdot \|$. Whether this linear rate for robust recovery can be achieved for other regularizers under the sole strong minimality assumption is an open question. Besides that main result, we also revisit in Theorem 3.10 robust recovery results when $x_0$ is assumed to be a sharp minimizer by proving linear convergence and providing more explicit bounds in comparison to the results in [10, 14, 19, 44].

- Our second main contribution, at the heart of Section 4, is to study necessary and sufficient conditions for the properties of sharp and strong minima. As mentioned above, solution uniqueness is characterized via the descent cone [10]. But it is hard to compute the descent cone for general functions $J$. On the other hand, sharp and strong minima can be characterized explicitly via first and second-order analysis [5, 28, 32]. We leverage these tools (see Theorem 4.6 and Proposition 4.12) to get equivalent characterizations of unique/sharp/strong solutions, and to obtain a quantitative condition for convex regularized problems that allows us to check numerically that a solution is sharp. This condition bears similarities with the Nondegenerate Source Condition of [19, 39, 42]. Our approach does not rely on any polyhedral structure. This distinguishes our results from several ones in the literature as in [17, 24, 44], and allows us to work on more general optimization problems. We also believe that non-smooth second-order analysis of the type we develop here, which is a powerful tool in variational analysis and nonsmooth optimization, is not well-known in the robust recovery literature, and are thus of particular importance in this context.

- Finally, Section 5 is devoted to a comprehensive treatment of unique/strong solutions for group-sparsity minimization problems [29, 33, 43], an important class of (1.2) where $J$ is the $\ell_1/\ell_2$ norm. Sufficient conditions for solution uniqueness for group-sparsity minimization problems were achieved in [7, 18, 21, 29, 33, 39, 42], but none of them are necessary. To find a characterization for solution uniqueness, we first obtain a closed form for the descent
cone (Theorem 5.1). To the best of our knowledge, this was an open question in the literature, though the statistical dimension of this cone is more computable [1]. By relying again on second-order analysis [5, 32], we show that a unique solution to group-sparsity minimization problems (1.2) and (1.5) is indeed a strong solution (Theorem 5.3). This result is interesting in two ways: first, the function in (1.2) is not piecewise linear-quadratic, which rules out the approach developed in [4] to unify solution uniqueness and strong minima; second, strong solutions are possibly more natural than sharp solutions for non-polyhedral minimization problems whenever solution uniqueness occurs. Moreover, we establish a quantitative condition for checking unique/strong solutions to group-sparsity problems that is equivalent to solving a smooth convex optimization problem. This convex problem can be solved via available packages such as cvxopt as we will illustrate in the numerical results of Section 6. Consequently, we show that solution uniqueness to group-sparsity problem is equivalent to the robust recovery with rate \( O(\sqrt{\delta}) \) for both problems (1.4) and (1.5).

Remark 1.1. Although we do not have a rigorous study for the case where \( J \) is the nuclear norm in this paper, we provide several examples showing that a unique solution to (1.2) with the nuclear norm is neither sharp nor strong. This raises the challenge of understanding the interplay between unique, sharp, and strong solutions in this case. Some open questions will be discussed in Section 7 for further research in this direction.

2 Preliminaries

Throughout the paper, \( \mathbb{R}^n \) is the Euclidean space with dimension \( n \). In \( \mathbb{R}^n \) we denote the inner product by \( \langle \cdot, \cdot \rangle \), the Euclidean norm by \( \| \cdot \| \), and the closed ball of radius \( r > 0 \) centered at \( x \in \mathbb{R}^n \) by \( B_r(x) \), and \( I \) the identity operator.

2.1 Some linear algebra

Given an \( m \times n \) matrix \( A \), Ker \( A \) (resp. Im \( A \)) is the kernel/null (resp. image) space of \( A \). The Moore-Penrose generalized inverse [22, Page 423] of \( A \) is denoted by \( A^\dagger \), which satisfies the property

\[
AA^\dagger A = A. \tag{2.1}
\]

Moreover, we have

\[
Ax = b \text{ is consistent if and only if } AA^\dagger b = b, \text{ and the set of solutions to } Ax = b \text{ is } A^\dagger b + \text{Ker } A. \tag{2.2}
\]

If \( A \) is injective then \( A^\dagger = (A^\top A)^{-1}A^\top \), where \( A^\top \) is the transpose of \( A \). If \( A \) is surjective then \( A^\dagger = A^\top (AA^\top)^{-1} \). \( A^* \) will also denote the adjoint of \( A \) as a linear operator.

Suppose that \( \bar{x} \) is a solution to the consistent system \( Ax = b \). The projection of \( x \in \mathbb{R}^n \) onto the affine set \( C \triangleq A^{-1}b \) is

\[
P_C(x) = (I - A^\dagger A)(x - \bar{x}) + \bar{x} = x - A^\dagger A(x - \bar{x}); \tag{2.3}
\]

see, e.g., [22, page 435–437]. Let \( \| \cdot \|_A \) and \( \| \cdot \|_B \) be two arbitrary norms in \( \mathbb{R}^m \) and \( \mathbb{R}^n \), respectively. The matrix operator norm \( \| \cdot \|_{A,B} : \mathbb{R}^{m \times n} \to \mathbb{R}_+ \) is defined by

\[
\| A \|_{A,B} \triangleq \max_{x \in \mathbb{R}^n \setminus \{0\}} \frac{\|Ax\|_A}{\|x\|_B}. \]

5
We write $\|A\|_{2,2}$ for $\|A\|$. The Frobenius norm of $A$ is known as
$$\|A\|_F = \sqrt{\text{Trace} (A^*A)}.$$
Recall that the nuclear norm of $A$ is
$$\|A\|_* = \sum_{k=1}^{\min(m,n)} \sigma_k,$$
where $\sigma_k$, $1 \leq k \leq \min(m,n)$ are all the singular values of $A$.

### 2.2 Some convex analysis

Let $\varphi : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a proper lower semi-continuous (lsc) convex function with domain $\text{dom} \varphi \overset{\text{def}}{=} \{x \in \mathbb{R}^n| \varphi(x) < \infty\}$. The subdifferential of $\varphi$ at $x \in \text{dom} \varphi$ is defined by
$$\partial \varphi (x) \overset{\text{def}}{=} \{v \in \mathbb{R}^n| \varphi(u) \geq \varphi(x) + \langle v, u - x \rangle, \ \forall u \in \mathbb{R}^n\}.$$ When $\varphi(\cdot) = \iota_C(\cdot)$, the indicator function of a nonempty closed convex set $C$, i.e., $\iota_C(x) = 0$ if $x \in C$ and $+\infty$ otherwise, the subdifferential of $\iota_C$ at $x \in C$ is the normal cone to $C$ at $x$:
$$N_C(x) \overset{\text{def}}{=} \{v \in \mathbb{R}^n| \langle v, u - x \rangle \leq 0, \ \forall u \in C\}. \tag{2.4}$$

For a set $\Omega \subset \mathbb{R}^n$, cone $\Omega$ is its conical hull, $\text{int} \Omega$ is the interior of $\Omega$, and $\text{ri} \Omega$ is the relative interior of the convex set $\Omega$. Given a convex cone $K \subset \mathbb{R}^n$, the polar of $K$ is defined to be the cone
$$K^\circ \overset{\text{def}}{=} \{v \in \mathbb{R}^n| \langle v, u \rangle \leq 0, \ \forall u \in \Omega\}. \tag{2.5}$$

It is well known, see [32, Corollary 6.21] that $K^\circ$ is closed and convex, and that
$$K^\circ = \text{cl} (K)^\circ \text{ and } K^{\circ\circ} = (K^\circ)^\circ = \text{cl} (K), \tag{2.6}$$
where cl denotes the topological closure. We will also use cl for the closure of a function, i.e., the topological closure of its epigraph.

The gauge function of $\Omega$ is defined by
$$\gamma_\Omega (u) \overset{\text{def}}{=} \inf \{r > 0| u \in r\mathbb{C}\}, \text{ for } u \in \mathbb{R}^n. \tag{2.7}$$
The support function to $\Omega$ is denoted by
$$\sigma_\Omega (v) \overset{\text{def}}{=} \sup_{x \in \Omega} \langle v, x \rangle, \text{ for } v \in \mathbb{R}^n. \tag{2.8}$$

It is a proper lsc convex function as soon as $\Omega$ is non-empty. The polar set of $\Omega$ is given by
$$\Omega^\circ \overset{\text{def}}{=} \{v \in \mathbb{R}^n| \sigma_C(v) \leq 1\}. \tag{2.9}$$

When $\Omega$ is a non-empty convex set, $\Omega^\circ$ is a non-empty closed convex set containing the origin. When $\Omega$ is also closed and contains the origin, it is well-known that
$$\iota_\Omega = \sigma_{\Omega^\circ}, \tag{2.10}$$
see, e.g., [30, Corollary 15.1.2]. In this case, $\iota_C$ is a non-negative lsc convex and positively homogeneous function.
2.3 Sharp and strong minima

Let us first recall the definition of sharp and strong solutions in \([5, 11, 28, 32]\) that are playing central roles throughout the paper.

**Definition 2.1** (Sharp and strong minima). We say \(\bar{x}\) to be a sharp solution/minimizer to the (non necessarily convex) function \(\varphi\) with a constant \(c > 0\) if there exists \(\varepsilon > 0\) such that

\[
\varphi(x) \geq \varphi(\bar{x}) + c\|x - \bar{x}\|, \quad \forall x \in B_\varepsilon(\bar{x}).
\]

Moreover, \(\bar{x}\) is said to be a strong solution/minimizer with a constant \(\kappa > 0\) if there exists \(\delta > 0\) such that

\[
\varphi(x) \geq \varphi(\bar{x}) + \frac{\kappa}{2}\|x - \bar{x}\|^2, \quad \forall x \in B_\delta(\bar{x}).
\]

Properties (2.11) and (2.12) are also known as respectively, first order and second order (or quadratic) growth properties.

Strong minima is certainly weaker than sharp minima. Moreover, if \(\bar{x}\) is a sharp or strong solution to \(\varphi\), it is a unique local minimizer to \(\varphi\) (and the unique minimizer if \(\varphi\) is convex). When the function \(\varphi\) is a convex piecewise linear convex, i.e., its epigraph is a polyhedral, \(\bar{x}\) is a unique solution to \(\varphi\) if and only if it is a sharp solution. Furthermore, if \(\varphi\) is a convex piecewise linear-quadratic function in the sense that its domain is a union of finitely many polyhedral sets, relative to each of which \(\varphi\) is a quadratic function, \(\bar{x}\) is a strong solution if and only if it is a unique solution, see, e.g., \([4]\).

To characterize sharp and strong solutions, it is typical to use directional derivative and second subderivative; see, e.g., \([5, 32]\).

**Definition 2.2** (directional derivative and second subderivative). Let \(\varphi: \mathbb{R}^n \to \overline{\mathbb{R}}\) be a proper lsc convex function. The directional derivative of \(\varphi\) at \(\bar{x}\) \(\in\) dom \(\varphi\) is the function \(d\varphi(\bar{x}) : \mathbb{R}^n \to \mathbb{R}\) defined by

\[
d\varphi(\bar{x})(w) \stackrel{\text{def}}{=} \lim_{t \downarrow 0} \frac{\varphi(\bar{x} + tw) - \varphi(\bar{x})}{t} \quad \text{for} \quad w \in \mathbb{R}^n.
\]

The second subderivative of \(\varphi\) at \(\bar{x}\) \(\in\) dom \(\varphi\) for \(\bar{\vartheta} \in \partial \varphi(\bar{x})\) is the function \(d^2\varphi(\bar{x}|\bar{\vartheta}) : \mathbb{R}^n \to \overline{\mathbb{R}}_+\) defined by

\[
d^2\varphi(\bar{x}|\bar{\vartheta})(w) \stackrel{\text{def}}{=} \lim_{t \downarrow 0, w' \to w} \frac{\varphi(\bar{x} + tw') - \varphi(\bar{x}) - t\langle \bar{\vartheta}, w' \rangle}{\frac{1}{2}t^2} \quad \text{for} \quad w \in \mathbb{R}^n.
\]

It is well-known that \(d\varphi(\bar{x})(w) = \max \{\langle v, w \rangle | v \in \partial \varphi(\bar{x})\}\) if \(\varphi\) is continuous at \(\bar{x}\). The calculation of \(d^2\varphi(\bar{x}|\bar{\vartheta})(w)\) is quite involved in general; see, e.g., \([5, 32, 23]\). Note that from \([32, \text{Proposition 13.5 and Proposition 13.20}]\), the function \(d^2\varphi(\bar{x}|\bar{\vartheta})\) is non-negative, lsc, positively homogeneous of degree \(2\), and

\[
\text{dom} \ d^2\varphi(\bar{x}|\bar{\vartheta}) \subset \mathcal{T}(\bar{x}|\bar{\vartheta}) \stackrel{\text{def}}{=} \{w \in \mathbb{R}^n | d\varphi(\bar{x})(w) = \langle \bar{\vartheta}, w \rangle\}.
\]

If, moreover, \(\varphi\) is twice-differentiable at \(\bar{x}\), we have (see \([32, \text{Example 13.8}]\))

\[
d^2\varphi(\bar{x}|\nabla \varphi(\bar{x}))(w) = \langle w, \nabla^2 \varphi(\bar{x})w \rangle.
\]

The following sum rule for second subderivatives will be useful.

**Lemma 2.3.** Let \(\varphi, \varphi : \mathbb{R}^n \to \overline{\mathbb{R}}\) be proper lsc convex functions with \(\bar{x} \in \text{dom} \ \varphi \cap \text{dom} \ \varphi\). Suppose that \(\varphi\) is twice-differentiable at \(\bar{x} \in \text{int} \ (\text{dom} \ \varphi)\) and \(\bar{\vartheta} \in \partial (\varphi + \phi)(\bar{x}) = \nabla \varphi(\bar{x}) + \partial \varphi(\bar{x})\). Then we have

\[
d^2(\varphi + \phi)(\bar{x}|\bar{\vartheta})(w) = \langle w, \nabla^2 \varphi(\bar{x})w \rangle + d^2\phi(\bar{x}|\bar{\vartheta} - \nabla \varphi(\bar{x}))(w) \quad \text{for all} \quad w \in \mathbb{R}^n.
\]
Proof. Use convexity of $\phi, \varphi$ and twice-differentiability of $\varphi$ at $\bar{x}$ into \cite[Proposition 13.19]{32}. □

The next result taken from \cite[Lemma 3, Chapter 5]{28} and \cite[Theorem 13.24]{32} characterize sharp and strong minima.

**Lemma 2.4 (Characterization of sharp and strong minima).** Let $\varphi : \mathbb{R}^n \to \mathbb{R}$ be a proper lsc convex function with $\bar{x} \in \text{dom } \varphi$. We have:

(i) $\bar{x}$ is a sharp minimizer to $\varphi$ if and only if there exists $c > 0$ such that $d\varphi(\bar{x})(w) \geq c\|w\|$ for all $w \in \mathbb{R}^n$, i.e., $d\varphi(\bar{x})(w) > 0$ for all $w \in \mathbb{R}^n \setminus \{0\}$.

(ii) $\bar{x}$ is a strong minimizer to $\varphi$ if and only if $0 \in \partial \varphi(\bar{x})$ and there exists $\kappa > 0$ such that $d^2\varphi(\bar{x}|0)(w) \geq \kappa\|w\|^2$ for all $w \in \mathbb{R}^n$, which means $\text{Ker } d^2\varphi(\bar{x}|0) \overset{\text{def}}{=} \{ w \in \mathbb{R}^n \mid d^2\varphi(\bar{x}|0)(w) = 0 \} = \{0\}$.

It is important to observe that although the sharpness of a minimizer as defined in (2.11) is a local property, it is actually a global one for convex problems.

**Lemma 2.5 (Global sharp minima).** Suppose that $\bar{x}$ is a sharp solution to the proper lsc convex function $\varphi$. Then there exists $c > 0$ such that $\varphi(x) - \varphi(\bar{x}) \geq c\|x - \bar{x}\|$ for all $x \in \mathbb{R}^n$.

Proof. Since $\bar{x}$ is a sharp solution to $\varphi$, we have from Lemma 2.4(i) that $\exists c > 0$ such that $d\varphi(\bar{x})(w) \geq c\|w\|$, $\forall w \in \mathbb{R}^n$. Thus, by the characterization of the directional derivative for convex functions, we have for any $x \in \mathbb{R}^n$

$$\varphi(x) - \varphi(\bar{x}) = \varphi(\bar{x} + (x - \bar{x})) - \varphi(\bar{x}) \geq \inf_{t > 0} \frac{\varphi(\bar{x} + t(x - \bar{x})) - \varphi(\bar{x})}{t} = d\varphi(\bar{x})(x - \bar{x}) \geq c\|x - \bar{x}\|.$$ 

The proof is complete. □

### 3 Unique, sharp, and strong solutions for robust recovery

#### 3.1 Uniqueness and robust recovery

Let us consider the optimization problem in (1.2) where we suppose that $J : \mathbb{R}^n \to \mathbb{R}$ is a non-negative lsc function but not necessarily convex. We denote by $J_\infty : \mathbb{R}^n \to \mathbb{R}$ the **asymptotic (or horizon) function** \cite{2} associated with $J$, which is defined by

$$J_\infty(w) \overset{\text{def}}{=} \liminf_{w' \to w, t \to \infty} \frac{J(tw')}{t}. \quad (3.1)$$

Throughout this section, we assume that $J$ satisfies

$$\text{Ker } J_\infty \cap \text{Ker } \Phi = \{0\}, \quad (3.2)$$

where $\text{Ker } J_\infty \overset{\text{def}}{=} \{ w \in \mathbb{R}^n \mid J_\infty(w) = 0 \}$, and the range of $J_\infty$ is on $\mathbb{R}_+$ since $J$ is non-negative. It then follows from \cite[Corollary 3.1.2]{2} that (3.2) ensures that problem (1.2) has a non-empty compact set of minimizers.
Define $\Psi : \mathbb{R}^n \rightarrow \mathbb{R}$ as
\[
\Psi(x) \overset{\text{def}}{=} f(x) + \iota_{\Phi^{-1}(x)}(x) \quad \text{for all } x \in \mathbb{R}^n.
\] (3.3)

We say that $x_0$ is a unique, sharp, or strong solution to (1.2) if it is a unique, sharp, or strong solution to the function $\Psi$, respectively.

Our first result shows that solution uniqueness is sufficient for robust recovery. If $J$ is also convex, then uniqueness is also necessary. The sufficiency part of our result generalizes the corresponding part of [20, Theorem 3.5] to nonconvex problems.

**Proposition 3.1** (Solution uniqueness for robust recovery). Suppose that $J$ is a non-negative lsc function which satisfies (3.2).

(i) If $x_0$ is the unique solution to problem (1.2) then:

(a) any solution $x_\delta$ to problem (1.4) with $\|y - y_0\| \leq \delta$ converges to $x_0$ as $\delta \rightarrow 0$,

(b) for any constant $c_1 > 0$, any solution $x_\mu$ to problem (1.5) with $\mu = c_1 \delta$ and $\|y - y_0\| \leq \delta$ converges to $x_0$ as $\delta \rightarrow 0$.

(ii) Conversely, if $J$ is convex and $\text{dom } J = \mathbb{R}^n$, then:

(a) (i)-(a) implies $x_0$ is the unique solution to (1.2).

(b) (i)-(b) implies $x_0$ is the unique solution to (1.2).

**Proof.** (i) Suppose that $x_0$ is the unique solution to problem (1.2). To justify (i)-(a), define the function $g \overset{\text{def}}{=} \iota_{\mathcal{B}_y} \circ \Phi$. We have, using [2, Propositions 2.6.1, 2.6.3 and 2.1.2], that
\[
(J + g)_\infty(w) \geq J_\infty(w) + g_\infty(w) = J_\infty(w) + (\iota_{\mathcal{B}_y} \circ \Phi)_\infty(w) = J_\infty(w) + \iota_{\text{Ker } \Phi}(w) \geq 0.
\]

Thus, under (3.2), the set of solutions to (1.4) is nonempty and compact thanks to [2, Corollary 3.1.2]. If $\{x_\delta\}_{\delta > 0}$ is unbounded, without passing to subsequences suppose that $\|x_\delta\| \rightarrow \infty$ and $\frac{x_\delta}{\|x_\delta\|} \rightarrow w$ as $\delta \downarrow 0$ with $\|w\| = 1$. We have
\[
0 \leq \left\| \Phi \left( \frac{x_\delta}{\|x_\delta\|} \right) - \frac{y}{\|x_\delta\|} \right\| \leq \frac{\delta}{\|x_\delta\|},
\]

and after passing to the limit, we get that $w \in \text{Ker } \Phi$. Moreover, since $x_0$ is a feasible point of (1.4), we have $J(x_\delta) \leq J(x_0)$, and thus
\[
0 = \liminf_{\delta \downarrow 0} \frac{J(x_0)}{\|x_\delta\|} \geq \liminf_{\delta \downarrow 0} \frac{J(x_\delta)}{\|x_\delta\|} \geq J_\infty(w) \geq 0,
\]

which means that $w \in \text{Ker } J_\infty$. This entails that $0 \neq w \in \text{Ker } J_\infty \cap \text{Ker } \Phi$, which contradicts (3.2). Thus $\{x_\delta\}_{\delta > 0}$ is bounded. Pick any subsequence $\{x_{\delta_k}\}_{k \in \mathbb{N}}$ of $\{x_\delta\}_{\delta > 0}$ converging to some $\bar{x}$ as $\delta_k \downarrow 0$. From lower semicontinuity of $J$ and of the norm, we get
\[
J(\bar{x}) \leq \liminf_k J(x_{\delta_k}) \leq J(x_0) \quad \text{and} \quad 0 \leq \|y_0 - \Phi \bar{x}\| \leq \liminf_k \|y_0 - \Phi x_{\delta_k}\| \leq 2 \lim_k \delta_k = 0.
\]

This means that $\bar{x}$ is a solution of (1.2), and by uniqueness of the minimizer, $\bar{x} = x_0$. Since the subsequence $\{x_{\delta_k}\}_{k \in \mathbb{N}}$ was arbitrary, we have $x_\delta \rightarrow x_0$ as $\delta \downarrow 0$, whence claim (i)-(a) follows.
(ii) Suppose now that \( J_2 \) This is known as the Source Condition \([34]\). If \( \eta \) have

thanks to uniqueness of the minimizer \( x \) which means

\[ (i)-(b) \text{ thanks to uniqueness of the minimizer } x \]

\[ \mu \text{ subdifferential calculus gives } \]

\[ \text{of the norm to show that any cluster point of } \]

\[ \text{The proof of (i)-(b) uses a similar reasoning. Let } g = \frac{1}{2} ||y - \cdot||^2 \circ \Phi. \] One has, using \([2, \text{Propositions 2.6.1, 2.6.3 and 2.6.7}], \)

\[ (\mu J + g)_{\infty}(w) \geq \mu J_{\infty}(w) + g_{\infty}(w) = \mu J_{\infty}(w) + \frac{1}{2} (\| \cdot \|)^{\infty}(\Phi w) = \mu J_{\infty}(w) + \iota_{\{0\}}(\Phi w) = \mu J_{\infty}(w) + \iota_{\text{Ker } \Phi}(w) \geq 0. \]

Hence the set of optimal solutions to problem (1.5) is nonempty and compact according to \([2, \text{Corollary 3.1.2}]. \) Similarly to part (i)-(a), we claim that \( \{x_\mu\}_{\mu > 0} \) is bounded. By contradiction, suppose again that \( \|x_\mu\| \to \infty \) and \( \frac{x_\mu}{\|x_\mu\|} \to z \) with \( \|z\| = 1. \) Note that by optimality of \( x_\mu \)

\[ \mu J(x_\mu) \leq \frac{1}{2} \|\Phi x_\mu - y\|^2 + \mu J(x_\mu) \leq \frac{1}{2} \|\Phi x_0 - y\|^2 + \mu J(x_0) \leq \frac{\delta^2}{2} + \mu J(x_0). \] (3.4)

As \( \mu = c_1 \delta, \) we obtain from (3.4) that

\[ 0 = \liminf_{\delta \downarrow 0} \frac{J(x_0) + \delta}{\|x_\mu\|} \geq \liminf_{\delta \downarrow 0} \frac{J(x_\mu)}{\|x_\mu\|} \geq J_\infty(z) \geq 0, \]

which means \( z \in \text{Ker } J_\infty. \) Furthermore, (3.4) also entails

\[ 0 \leq \frac{1}{2} \left\| \Phi \left( \frac{x_\mu}{\|x_\mu\|} \right) - \frac{y}{\|x_\mu\|} \right\|^2 \leq \frac{1}{\|x_\mu\|^2} \left( \frac{\delta^2}{2} + \mu J(x_0) \right), \]

which tells us, after passing to the limit, that \( 0 \neq z \in \text{Ker } J_\infty \cap \text{Ker } \Phi, \) hence contradicting (3.2). Thus \( \{x_\mu\}_{\mu > 0} \) is bounded. Arguing as in (i)-(a), we use lower semicontinuity of \( J \) and of the norm to show that any cluster point of \( \{x_\mu\}_{\mu > 0} \) is a solution of (1.2), and deduce claim (i)-(b) thanks to uniqueness of the minimizer \( x_0. \)

(ii) Suppose now that \( J \) is also convex and \( \text{dom } J = \mathbb{R}^n \) (hence continuous). If (i)-(a) holds, we have

\[ J(x_\delta) \leq J(x) \text{ for any } x \text{ such that } \|y - \Phi x\| \leq \delta \text{ and } \|y - y_0\| \leq \delta. \] (3.5)

It follows that

\[ J(x_\delta) \leq J(x) \text{ for any } x \text{ such that } \Phi x = y_0. \]

By letting \( \delta \downarrow 0, \) and using continuity of \( J, \) we obtain that \( x_0 \) is a minimizer to (1.2). Let \( \bar{x} \) be an arbitrary minimizer to problem (1.2). As \( \text{dom } J = \mathbb{R}^n, \) Fermat’s rule for (1.2) and subdifferential calculus gives

\[ 0 \in \partial \Psi(\bar{x}) = \partial J(\bar{x}) + N_{\Phi^{-1}y_0}(\bar{x}) = \partial J(\bar{x}) + \text{Im } \Phi^*. \] (3.6)

Or, equivalently, there exists a dual multiplier \( \eta \in \mathbb{R}^m \) such that \( \Phi^* \eta \in \partial J(\bar{x})^2. \) If \( \eta = 0, \) we have \( 0 \in \partial J(\bar{x}), \) which means that \( \bar{x} \) is a minimizer to \( J. \) Thus, \( \bar{x} \) is also a minimizer to problem (1.4) for any \( \delta > 0. \) By (i)-(a), \( \bar{x} - x_0 \to 0 \) as \( \delta \downarrow 0, \) i.e., \( \bar{x} = x_0. \)

If \( \eta \neq 0, \) take any \( \delta > 0 \) and define \( \mu = \frac{\delta}{\|\eta\|} \) and \( y \overset{\text{def}}{=} y_0 + \mu \eta = \Phi \bar{x} + \mu \eta. \) It follows that

\[ \|y - \Phi \bar{x}\| = \|y - y_0\| = \delta \text{ and that } \]

\[ \frac{1}{\mu} \Phi^*(y - \Phi \bar{x}) = \Phi^* \eta \in \partial J(\bar{x}). \] (3.7)

\[^2\text{This is known as the Source Condition } [34].\]
On the other hand, under our assumption, we have that $x^*$ is a solution to (1.4) if and only if

$$0 \in \partial J(x^*) + \Phi^* N_{B(y)}(\Phi x^*),$$

where $N_{B(y)}(\Phi x^*) = \mathbb{R}_+ (\Phi x^* - y)$ whenever $\|y - \Phi x^*\| = \delta$. This is precisely the optimality condition verified by $\bar{x}$ in (3.7), which shows that $\bar{x}$ is also a solution to (1.4). By (i)-(a) again, we have $\bar{x} = x_0$. Since the choice of $\bar{x}$ is arbitrary, $x_0$ is the unique solution to (1.2).

Finally, suppose that (i)-(b) is satisfied. We have for any $x \in \Phi^{-1} y_0$ that

$$\mu J(x_\mu) \leq \frac{1}{2} \|\Phi x - y\|^2 + \mu J(x) \leq \frac{\delta^2}{2} + \mu J(x).$$

Dividing both sides by $\mu = c_1 \delta$ and letting $\delta \to 0$ entails $J(x_0) \leq J(x_\mu)$ for any $x \in \Phi^{-1} y_0$, which is equivalent to saying that $x_0$ is a solution to problem (1.2). The proof of uniqueness follows similar lines as for problem (1.4) with the choice $y = \Phi \bar{x} + \mu \eta$ and $\mu = c_1 \delta$. Note that under our assumption, Fermat’s rule for problem (1.5) is (3.7) without further qualification condition unlike what is required for (1.4).

\[\Box\]

Remark 3.2. In the convex case, the condition (3.2) is superfluous in Proposition 3.1(i). Indeed, (3.2) is equivalent in this case to the fact the set of minimizers of (1.2) is a non-empty compact set, which is obviously the case when $x_0$ is the unique minimizer.

### 3.2 Sharp minima and robust recovery

A sufficient and necessary condition for uniqueness to problem (1.2), together with its implication for robust recovery, is studied in [10] via the key geometric notion of descent cone that we recall now.

**Definition 3.3 (Descent cone).** The descent cone of the function $J$ at $x_0$ is defined by

$$D_J(x_0) \overset{\text{def}}{=} \text{cone} \{ x - x_0 | J(x) \leq J(x_0) \}. \quad (3.8)$$

The following proposition provides a characterization for solution uniqueness whose proof can be found in [10, Proposition 2.1].

**Proposition 3.4 (Descent cone for solution uniqueness [1, 10]).** Then $x_0$ is the unique solution to (1.2) if and only if $\text{Ker } \Phi \cap D_J(x_0) = \{0\}$.

In [10, Proposition 2.2] (see also [36, Proposition 2.6]), the authors also prove a robust recovery result for solutions of (1.4) via the descent cone.

**Proposition 3.5 (Robust recovery via descent cone [10]).** Let suppose that there exists some $\alpha > 0$ such that $\|\Phi w\| \geq \alpha \|w\|$ for all $w \in D_J(x_0)$. Then any solution $x_\delta$ to problem (1.4) satisfies

$$\|x_\delta - x_0\| \leq \frac{2\delta}{\alpha}. \quad (3.9)$$

The parameter $\alpha$ is known as the minimum conic singular value of $\Phi$ with respect to the cone $D_J(x_0)$. One may observe that the condition in Proposition 3.5 is not the same with the one for solution uniqueness in Proposition 3.4. The reason is that the descent cone $D_J(x_0)$ is not necessarily
closed in general. To see this, we first unveil the relation between the descent and critical cones. Denote
\[ L_{x_0}(J) \overset{\text{def}}{=} \{ x \in \mathbb{R}^n \mid J(x) \leq J(x_0) \} \]
the sublevel set of \( J \) at \( x_0 \). The critical cone of a convex function \( J \) at \( x_0 \) is
\[ C_J(x_0) \overset{\text{def}}{=} \{ w \in \mathbb{R}^n \mid dJ(x_0)(w) \leq 0 \}. \] (3.10)

**Lemma 3.6** (Relationship between descent cone and critical cone). Suppose that \( J \) is a continuous convex function. Then,
\[ D_J(x_0) \subset \text{cl}(D_J(x_0)) \subset C_J(x_0). \] (3.11)

If moreover \( 0 \not\in \partial J(x_0) \), then
\[ \text{cl}(D_J(x_0)) = C_J(x_0). \] (3.12)

**Proof.** We have from (2.6) that
\[ \text{cl}(D_J(x_0)) = (D_J(x_0))^\circ = ((\text{cl}D_J(x_0))^\circ)^\circ = (N_{L_{x_0}(J)}(x_0))^\circ \subset C_J(x_0), \] (3.13)
where we used (2.6) in the first two equalities, polarity in the third, and convexity and the first claim of [32, Proposition 10.3] in the last equality. If in addition \( 0 \not\in \partial J(x_0) \), then using [30, Corollary 23.7.1] and the last claim of [32, Proposition 10.3], the inclusion in (3.13) becomes
\[ \text{cl}(D_J(x_0)) = (N_{L_{x_0}(J)}(x_0))^\circ = (\text{cone} \partial J(x_0))^\circ = C_J(x_0). \] (3.14)

When \( J \) is also positively homogenous, the requirement \( 0 \not\in \partial J(x_0) \) in Lemma 3.6 can be dropped.

**Proposition 3.7.** Suppose that \( J = \sigma_C \), where \( C \subset \mathbb{R}^n \) is a non-empty compact convex set with \( 0 \in \text{ri } C \). Then, (3.12) holds at any \( x_0 \in \mathbb{R}^n \).

**Proof.** Thanks to the assumptions on \( C \), we have from [30, Theorem 13.2 and Corollary 13.3.1] that \( J \) convex, positively and homogenous and finite everywhere, hence continuous. We now only consider the case where \( 0 \in \partial J(x_0) \) as, otherwise, the result claim follows from Lemma 3.6. By [40, Lemma 1], \( J \) is also non-negative and \( \text{Ker } J \) is a linear subspace. This entails that \( 0 \in \partial J(x_0) \) is equivalent to \( x_0 \in \text{Ker } J \), and thus from (3.8), that
\[ D_J(x_0) = \text{cone} (\text{Ker } J - x_0) = \text{Ker } J. \]

On the other hand, we have from (3.10) that
\[ C_J(x_0) = (\partial J(x_0))^\circ = (\text{cone} \partial J(x_0))^\circ = N_{\partial J(x_0)}(0). \]

Moreover, by [32, Corollary 8.25]
\[ \partial J(x_0) = C \cap \{ x_0 \}^\perp. \]

Combining this with [32, Theorem 6.42] (recall that \( C \) is convex and \( 0 \in \text{ri } C \cap \{ x_0 \}^\perp \)), we get
\[ C_J(x_0) = N_{C \cap \{ x_0 \}^\perp}(0) = N_C(0) + \mathbb{R}x_0 = \text{Ker } J + \mathbb{R}x_0 = \text{Ker } J, \]
where the last equality comes from the fact that \( \text{Ker } J \) is a linear subspace containing \( x_0 \). This completes the proof. \[ \square \]
We now turn to showing that the condition in Proposition 3.5 actually means that $x_0$ is a sharp solution to (1.2).

**Proposition 3.8** (Characterization of sharp minima via the descent and critical cones). Let $J$ be a continuous function.

(i) $x_0$ is a sharp solution to (1.2) if and only if $\ker \Phi \cap C_f(x_0) = \{0\}$.

(ii) If $J = \sigma_C$, where $C \subset \mathbb{R}^n$ is a non-empty compact convex set with $0 \in \text{ri} C$, then $x_0$ is a sharp solution to (1.2) if and only if there exists $\alpha > 0$ such that $\|\Phi w\| \geq \alpha \|w\|$ for all $w \in D_f(x_0)$.

**Proof.** (i) Recall $\Psi$ from (3.3). We have

$$d\Psi(x_0)(w) = dJ(x_0)(w) + i_{\ker \Phi}(w).$$

By Lemma 2.4, $x_0$ is a sharp solution to (1.2) if and only if $d\Psi(x_0)(w) > 0$ for all $w \in \mathbb{R}^n \setminus \{0\}$. Combining this with (3.10) and (3.15) leads the claimed equivalence.

(ii) Assume $x_0$ is a sharp solution to (1.2). Since $C_f(x_0)$ is closed, we have from claim (i) that there exists $\alpha > 0$ such that $\|\Phi w\| \geq \alpha \|w\|$ for all $w \in C_f(x_0)$. We then get the first implication from the inclusion (3.11). Conversely, if there is $\alpha > 0$ such that $\|\Phi w\| \geq \alpha \|w\|$ for all $w \in D_f(x_0)$, we have $\|\Phi w\| \geq \alpha \|w\|$ for all $w \in C_f(x_0)$ thanks to Proposition 3.7. It follows that $\ker \Phi \cap C_f(x_0) = \{0\}$. This implies, in view of claim (i), that $x_0$ is a sharp solution to (1.2).

The main lesson we learn from the above, in particular Proposition 3.4 and Proposition 3.8, is that there is a gap between solution uniqueness and solution sharpness (hence robust recovery via Proposition 3.5) for problem (1.2). This difference lies in the closedness of the descent cone. Indeed, when the descent cone $D_f(x_0)$ is closed, it coincides with the critical cone $C_f(x_0)$. Unfortunately, in general, $D_f(x_0)$ is not closed. A prominent example where $D_f(x_0)$ may fail to be closed is that of the $\ell_1/\ell_2$ norm very popular to promote group sparsity. The following example is a prelude of our precise formula for the descent cone of the $\ell_1/\ell_2$ norm in Theorem 5.1, in which the interior of the critical cone $C_f(x_0)$ plays a significant role.

**Example 3.9** (Gap between solution uniqueness and sharpness for group-sparsity). Consider the following $\ell_1/\ell_2$ norm minimization problem:

$$\min_{x \in \mathbb{R}^3} J(x) = \sqrt{x_1^2 + x_2^2 + |x_3|} \quad \text{subject to} \quad \Phi x = y_0,$$

with $\Phi = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 0 & -1 \end{pmatrix}$, $x_0 = (0, 1, 0)^\top$, and $y_0 = \Phi x_0 = (1, 0)^\top$. We have $\ker \Phi = \mathbb{R}(1, -1, 1)^\top$, and feasible points of (3.16) then take the form $x = x_0 + t(1, -1, 1)^\top$ for any $t \in \mathbb{R}$. For all such points, we have

$$J(x) - J(x_0) = \sqrt{t^2 + (1-t)^2} + |t| - 1 = \frac{t^2 + 2(|t| - t)}{\sqrt{t^2 + (1-t)^2} + 1 - |t|},$$

which tells us that $x_0$ is the unique solution to (3.9). In fact, simple calculation shows that $x_0$ is a strong but not a sharp solution to (3.9). For $J$ in (3.16), Figure 1 illustrates the difference between the descent cone computed by Theorem 5.1 and the critical cone (3.10) whose computation is straightforward in this case. It is obvious that $\ker \Phi \cap C_f(x_0) \neq \{0\}$, though $\ker \Phi \cap D_f(x_0) = \{0\}$ (which is indeed equivalent to solution uniqueness).
Figure 1: The descent cone $\mathcal{D}_J(x_0)$ and critical cone $\mathcal{C}_J(x_0)$ for $J$ in (3.16). Here, $\mathcal{D}_J(x_0) = (\mathcal{E} \cap \text{bd} \mathcal{C}_J(x_0)) \cup \text{int} \mathcal{C}_J(x_0)$, where $\mathcal{E} = \{(0, x_2, x_3) | x_2, x_3 \in \mathbb{R}\}$ (see (5.8)) and $\mathcal{C}_J(x_0) = \{(x_1, x_2, x_3) | x_2 + |x_3| \leq 0\}$. The green shaded surface is $\text{bd} \mathcal{C}_J(x_0)$ and the blue half-lines correspond to $\mathcal{E} \cap \text{bd} \mathcal{C}_J(x_0)$.

Inspired by Proposition 3.5, we show next that sharpness of the minimizer guarantees robust recovery for both problems (1.4) and (1.5) with linear rate. Unlike [10, Proposition 2.2] and many other results [14, 19, 39, 42, 44] in this direction, we do not need convexity of $J$. In fact, the key is to assume that $x_0$ is a unique and sharp solution to problem (1.2).

**Theorem 3.10** (Sharp minima for robust recovery). Suppose that $J$ is a non-negative lsc function which satisfies (3.2), and is Lipschitz continuous around $x_0$ with modulus $L$. If $x_0$ is the unique and sharp solution to (1.2) with constant $c > 0$, then for all $\delta > 0$ sufficiently small, the following statements hold:

(i) Any solution $x_\delta$ to problem (1.4) satisfies

$$\|x_\delta - x_0\| \leq \frac{2(L + c)\|\Phi^+\|}{c} \delta.$$  \hspace{1cm} (3.17)

(ii) For any $c_1 > 0$ and $\mu = c_1 \delta$, any minimizer $x_\mu$ to (1.5) satisfies

$$\|x_\mu - x_0\| \leq \frac{c_1}{2c} \left( \frac{1}{c_1} + (c + L)\|\Phi^+\| \right)^2 \delta.$$  \hspace{1cm} (3.18)

**Proof.**  (i) $L$-Lipschitz continuity of $J$ around $x_0$ entails that $\exists \varepsilon > 0$ such that

$$|J(x) - J(z)| \leq L\|x - z\| \quad \text{for all} \quad x, z \in \mathbb{B}_\varepsilon(x_0).$$  \hspace{1cm} (3.19)

Since $x_0$ is a sharp solution to (1.2) with constant $c$, there exists $\eta > 0$ such that

$$J(x) - J(x_0) \geq c\|x - x_0\| \quad \text{for all} \quad x \in \Phi^{-1}y_0 \cap \mathbb{B}_\eta(x_0).$$  \hspace{1cm} (3.20)

Let $\tilde{x}_\delta$ be the projection of $x_\delta$ onto $\Phi^{-1}y_0$. Thus

$$\|\tilde{x}_\delta - x_0\| \leq \|x_\delta - \tilde{x}_\delta\| + \|x_\delta - x_0\| \leq 2\|x_\delta - x_0\|.$$  \hspace{1cm} (3.21)
Since $x_0$ is the unique solution to problem \((1.2)\), Proposition 3.1(i) tells us that for all $\delta$ small enough, $x_\delta \in \mathbb{B}_{\min(\varepsilon, \eta)}/2(x_0)$ and, by \((3.21)\), $\bar{x}_\delta \in \mathbb{B}_{\min(\varepsilon, \eta)}(x_0)$, i.e., $x_\delta, \bar{x}_\delta \in \mathbb{B}_{\min(\varepsilon, \eta)}(x_0)$ with $\varepsilon, \eta$ in \((3.19)\) and \((3.20)\). We then have

\[
L\|\bar{x}_\delta - x_\delta\| \geq J(\bar{x}_\delta) - J(x_\delta) \quad \text{by} \ (3.19), \\
\geq J(x_\delta) - J(x_0) \quad \text{by optimality of} \ x_0, \\
\geq c\|\bar{x}_\delta - x_0\| \quad \text{by} \ (3.20), \\
\geq c\|x_\delta - x_0\| - c\|x_\delta - \bar{x}_\delta\|.
\]

Combining this with the projection formula \((2.3)\) tells us that

\[
c\|x_\delta - x_0\| \leq (L + c)\|x_\delta - \bar{x}_\delta\| = (L + c)\|\Phi^*\Phi(x_\delta - x_0)\|
\leq (L + c)\|\Phi^*\||\Phi(x_\delta - x_0)||
\leq (L + c)\|\Phi^*\|(\|y - \Phi x_\delta\| + \|y - \Phi x_0\|)
\leq (L + c)\|\Phi^*\|2\delta,
\]

which is \((3.17)\).

(ii) Optimality of $x_\mu$ gives

\[
J(x_\mu) - J(x_0) \leq \frac{1}{2\mu} \left(\|y - \Phi x_0\|^2 - \|y - \Phi x_\mu\|^2\right)
\leq \frac{1}{2\mu} \left(\|y - \Phi x_0\|^2 - (\|y - \Phi x_0\| - \|\Phi(x_\mu - x_0)\|)^2\right)
= \frac{1}{2\mu} \left(2\delta\|\Phi(x_\mu - x_0)\| - \|\Phi(x_\mu - x_0)\|^2\right). \tag{3.22}
\]

Let $\bar{x}_\mu$ be the projection of $x_\mu$ to $\Phi^{-1}y_0$. Inequality \((3.21)\) remains valid for $x_\mu$ and $\bar{x}_\mu$ replacing $x_\delta$ and $\bar{x}_\delta$ respectively. Moreover, arguing as in the proof of claim (i), but now invoking Proposition 3.1(ii), we infer that for $\delta$ sufficiently small, $x_\mu, \bar{x}_\mu \in \mathbb{B}_{\min(\varepsilon, \eta)}(x)$, where $\varepsilon, \eta$ are those in \((3.19)\) and \((3.20)\). Denote for short $\alpha = \|\Phi(x_\mu - x_0)\|$. We then get

\[
J(x_\mu) - J(x_0) = J(\bar{x}_\mu) - J(x_0) + J(x_\mu) - J(\bar{x}_\mu)
\geq c\|\bar{x}_\mu - x_0\| - L\|x_\mu - \bar{x}_\mu\| \quad \text{by} \ (3.20) \text{ and} \ (3.19),
\geq c\|x_\mu - x_0\| - (c + L)\|x_\mu - \bar{x}_\mu\|
= c\|x_\mu - x_0\| - (c + L)\|\Phi^*\Phi(x_\mu - x_0)\| \quad \text{by} \ (2.3),
\geq c\|x_\mu - x_0\| - (c + L)\|\Phi^*\|\alpha.
\]

This together with \((3.22)\) gives us that

\[
c\|x_\mu - x_0\| \leq \frac{2\delta\alpha - \alpha^2}{2\mu} + (c + L)\|\Phi^*\|\alpha
= \left(\frac{\delta}{\mu} + (c + L)\|\Phi^*\|\right)\alpha - \frac{\alpha^2}{2\mu} \tag{3.23}
\leq \frac{\mu}{2} \left(\frac{\delta}{\mu} + (c + L)\|\Phi^*\|\right)^2,
\]

which is clearly \((3.18)\) for the choice $\mu = c_1\delta$. \qed
The bounds (3.17) and (3.18) in Theorem 3.10 hold without convexity with the proviso that \( \delta \) is sufficiently small. However, when the function \( J \) is convex and continuous, the bounds are satisfied for any \( \delta > 0 \).

**Corollary 3.11** (Sharp minima for robust recovery under convexity). *Suppose that \( J \) is a convex continuous function. If \( x_0 \) is a sharp solution to (1.2), then statements (i) and (ii) of Theorem 3.10 hold for any \( \delta > 0 \) with some constant \( L > 0 \).

**Proof.** When \( J \) is a continuous convex function and \( x_0 \) is a sharp solution to (1.2), it follows from Lemma 2.5 that the sharpness property (3.20) is global and \( x_0 \) is also the unique solution to (1.2). In turn, \( J \) satisfies (3.2) in view of Remark 3.2. Therefore, the nets \( \{ x_\delta \}_{\delta > 0}, \{ x_\mu \}_{\mu > 0} \) are bounded as proved in Proposition 3.1. Thus, there exists some \( R > 0 \) such that \( x_0, x_\delta, x_\mu, \bar{x}_\mu \in \mathbb{B}_R(0) \). Convexity and continuity of \( J \) also imply that it is Lipschitz continuous on \( \mathbb{B}_{2R}(x_0) \) with some Lipschitz constant \( L > 0 \). Overall, this tells us that we can take \( \epsilon, \eta \) in (3.19) and (3.20) in the proof of Theorem 3.10 by \( 2R \). The rest of the proof remains valid, whence our claim follows. \[ \square \]

**Discussion of related work** It is worth noting that Corollary 3.11 covers many results in [14, 19, 39, 13, 42, 44]. When \( J = \| \cdot \|_A \) is a norm in \( \mathbb{R}^n \), claim (i) of Corollary 3.11 is exactly [10, Proposition 2.2] (see Proposition 3.5) thanks to Proposition 3.8(ii). In this case the Lipschitz constant \( L \) of \( J \) is \( \| I \|_{A,2} \).

For the case \( J = \| \cdot \|_A \), Corollary 3.11 returns [19, Theorem 4.7] (see also [13, Proposition 1]) whose proof is less transparent and involves deriving linear convergence rate of the Bregman divergence of \( J \), together with the characterizations of solution uniqueness to \( \ell_1 \) optimization problems via the so-called restricted injectivity and non-degenerate source condition.

When \( J(x) = \| D^*x \|_A \) with \( D \) being an \( n \times p \) matrix and \( \| \cdot \|_A \) being a norm in \( \mathbb{R}^p \), the Lipschitz constant \( L \) of \( J \) is \( \| I \|_{A,2} \| D^* \| \). Corollary 3.11 covers [14, Theorem 2]. Another result in this direction is [44, Theorem 2], which only obtains linear rate for \( \| D^*(x_\mu - x_0) \| \) with extra nontrivial assumptions on \( D \).

When \( J \) is a general convex continuous regularizer as in Corollary 3.11, [39, 42] use the so-called restricted injectivity and non-degenerate source condition at \( x_0 \) to obtain robust recovery. In our forthcoming Theorem 4.6, we will show that these two conditions are equivalent to \( x_0 \) being a sharp solution\(^3\). It means that Corollary 3.11 is equivalent to [39, Theorem 6.1] or [42, Theorem 2]. However, our path to proving robust recovery is radically different. On the one hand, [39, Theorem 6.1] generalizes the proof strategy initiated in [19] and use decomposability of \( J \) and other arguments that heavily rely on convexity of \( J \). On the other hand, Corollary 3.11 provides a direct proof that involve natural geometrical properties of \( J \) around \( x_0 \). Most importantly, Theorem 3.10 suggests that robust recovery with linear rate occurs without convexity and reveals the crucial role played by sharpness of the minimizer to achieve robust recovery with linear rate. Comparing the constants in our bounds (3.18)-(3.17) and those in [39, 42], those in [39, 42] depend for instance on a dual certificate and its ”distance” to degeneracy, while ours depend on the sharpness parameter \( c \) which is not trivial to characterize at first glance. In Theorem 4.6, we will provide an estimation for \( c \) via the so-called Source Identity that can be computed numerically.

### 3.3 Strong minima and robust recovery

A natural question is to whether robust recovery is still possible if the sharp minima property is replaced by the weaker strong minima property. We here show that the answer is affirmative, but at the price of a slower rate of convergence.

\(^3\)The authors in [39, 42] have already proved that these two conditions are sufficient for \( x_0 \) to be a sharp solution.
Theorem 3.12 (Strong minima for robust recovery). \textit{Suppose that $J$ is a non-negative lsc function which satisfies (3.2), and is Lipschitz continuous around $x_0$ with modulus $L$. If $x_0$ is the unique and strong solution to (1.2) with constant $\kappa > 0$, then for all $\delta > 0$ sufficiently small, the following statements hold:}

(i) \textit{Any solution $x_\delta$ to problem (1.4) satisfies}

$$
\|x_\delta - x_0\| \leq 2 \left( \frac{1}{\kappa} L \|\Phi^+\| \delta + \|\Phi^+\|^2 \delta^2 \right)^{\frac{1}{2}}. 
$$

(ii) \textit{For any $c_1 > 0$ and $\mu = c_1 \delta$, any minimizer $x_\mu$ to (1.5) obeys}

$$
\|x_\mu - x_0\| \leq \sqrt{\frac{c_1}{1 - c_1 \kappa \|\Phi^+\|^2 \delta}} \left( \frac{1}{c_1} + L \|\Phi^+\| \right) \delta^\frac{1}{2}.
$$

\textbf{Proof.} \textit{(i) Since $x_0$ is a strong solution to (1.2) with constant $\kappa > 0$, there exists $\nu > 0$ such that}

$$
J(x) - J(x_0) \geq \frac{\kappa}{2} \|x - x_0\|^2 \quad \text{for all } x \in \Phi^{-1} y_0 \cap B_{\nu}(x_0).
$$

Let $\bar{x}_\delta$ be the projection of $x_\delta$ onto $\Phi^{-1} y_0$. Since $x_0$ is the unique solution to problem (1.2), we argue as in the proof of Theorem 3.10(i) to show that for all $\delta$ small enough, one has $\bar{x}_\delta, x_\delta \in B_{\min\{\epsilon, \nu\}}(x_0)$ with $\epsilon, \nu$ in (3.19) and (3.26). We then have

$$
L \|\bar{x}_\delta - x_\delta\| \geq J(\bar{x}_\delta) - J(x_\delta)
$$

by (3.19),

$$
\geq J(x_\delta) - J(x_0)
$$

by optimality of $x_0$,

$$
\geq \frac{\kappa}{2} \|\bar{x}_\delta - x_0\|^2
$$

by (3.26),

$$
= \frac{\kappa}{2} \left( \|x_\delta - x_0\|^2 - \|\bar{x}_\delta - x_\delta\|^2 \right). 
$$

by (2.3).

This together with (2.3) again tells us that

$$
\frac{\kappa}{2} \|x_\delta - x_0\|^2 \leq L \|\bar{x}_\delta - x_\delta\| + \frac{\kappa}{2} \|\bar{x}_\delta - x_\delta\|^2
$$

$$
= L \|\Phi^+ \Phi(x_\delta - x_0)\| + \frac{\kappa}{2} \|\Phi^+ \Phi(x_\delta - x_0)\|^2
$$

$$
\leq L \|\Phi^+\| \|\Phi x_\delta - y_0\| + \frac{\kappa}{2} \|\Phi^+\|^2 \|\Phi x_\delta - y_0\|^2
$$

$$
\leq L \|\Phi^+\|^2 \|\Phi x_\delta - y_0\| \leq \frac{\kappa}{2} \|\Phi^+\|^2 4 \delta^2,
$$

which is (3.24).

(ii) \textit{Let $\bar{x}_\mu$ be the projection of $x_\mu$ to $\Phi^{-1} y_0$. Arguing as above, we infer that for $\delta$ sufficiently small, $x_\mu, \bar{x}_\mu \in B_{\min\{\epsilon, \nu\}}(\bar{x})$, where $\epsilon, \eta$ are those in (3.19) and (3.26). Set for short $\alpha = \|\Phi(x_\mu - x_0)\|$. We then have}

$$
J(x_\mu) - J(x_0) = J(\bar{x}_\mu) - J(x_0) + J(x_\mu) - J(\bar{x}_\mu)
$$

$$
\geq \frac{\kappa}{2} \|x_\mu - x_0\|^2 - L \|\bar{x}_\mu - x_\mu\|
$$

by (3.26) and (3.19),

$$
= \frac{\kappa}{2} \left( \|x_\mu - x_0\|^2 - \|\bar{x}_\mu - x_\mu\|^2 \right) - L \|\bar{x}_\mu - x_\mu\|
$$

by (2.3),

$$
= \frac{\kappa}{2} \|x_\mu - x_0\|^2 - \|\Phi^+ \Phi(x_\mu - x_0)\|^2 - L \|\Phi^+ \Phi(x_\mu - x_0)\|
$$

by (2.3),

$$
\geq \frac{\kappa}{2} \left( \|x_\mu - x_0\|^2 - \|\Phi^+\|^2 \alpha^2 \right) - L \|\Phi^+\| \alpha.
$$
Combining this with (3.22), we arrive at
\[ \frac{\kappa}{2} \left( \|x_\mu - x_0\|^2 - \|\Phi^\dagger\|^2 \alpha^2 \right) - L\|\Phi^\dagger\|\alpha \leq \frac{2\alpha\delta - \alpha^2}{2\mu}. \]

Making \( \delta \) smaller if necessary so that \( \mu = c_1\delta < \left( \kappa\|\Phi^\dagger\|^2 \right)^{-1} \), we get
\[
\frac{\kappa}{2} \|x_\mu - x_0\|^2 \leq \left( \frac{\delta}{\mu} + L\|\Phi^\dagger\| \right) \alpha - \left( \frac{1}{2\mu} - \frac{\kappa}{2}\|\Phi^\dagger\|^2 \right) \alpha^2 \\
\leq \frac{1}{2} \left( \frac{1}{\mu} - \kappa\|\Phi^\dagger\|^2 \right)^{-1} \left( \frac{\delta}{\mu} + L\|\Phi^\dagger\| \right)^2,
\]
which is (3.24) after some simple algebra.

When the regularizer \( J \) is convex, the Lipschitz property of \( J \) around \( x_0 \) is equivalent to the continuity of \( J \) at \( x_0 \); see, e.g., [3, Theorem 8.29]. Moreover, the assumption that \( x_0 \) is the unique minimizer of (1.2) holds trivially when \( x_0 \) is a strong minimizer. We then obtain the following corollary of Theorem 3.12.

**Corollary 3.13.** Suppose that \( J \) is a convex function that is continuous at \( x_0 \). If \( x_0 \) is a strong solution to problem (1.2) then, for \( \delta \) sufficiently small, the convergence rate \( O(\delta^{1/2}) \) of Theorem 3.12 holds.

**Remark 3.14.** Observe that unlike sharp minima, even for the convex case, the property of strong minima is only local. This is the reason we still require \( \delta \) to be small enough in Corollary 3.13. This is in stark contrast to Corollary 3.11 where sharpness is globalized under convexity.

**Remark 3.15.** A natural and open question is whether the rate \( O(\delta^{1/2}) \) in Theorem 3.12 is optimal under the strong solution property. Though we do not have a clear answer yet, we believe that his may depend on the type of regularizer. For the case of Euclidean norm \( J(x) = \|x\| \), we could prove that the rate could be improved to \( O(\delta) \). We omit the details here for the sake of brevity.

## 4 Nondegeneracy, restricted injectivity and sharp minima

As shown in Proposition 3.8, sharp minima can be characterized via the descent and critical cones. However, it is not easy to verify them numerically, especially when the dimension is large\(^4\). In this section, we mainly derive quantitative characterizations for sharp minima to problem (1.2).

Throughout this section, we suppose that \( J \) takes the analysis-type form
\[ J = J_0 \circ D^*, \]  
where \( D^* : \mathbb{R}^n \to \mathbb{R}^p \) is linear, and \( J_0 \) is a non-negative, convex and continuous function. The reason we take this form is twofold. First, this is in preparation for Section 5 to make the presentation easier there. Second, though we could derive the decomposability properties (see shortly) of \( J \) from those of \( J_0 \) using the framework in [40], our analysis in this section will involve a dual multiplier which is not the same as the one in that paper.

For some linear subspace \( V \) of \( \mathbb{R}^n \), we will use the shorthand notation \( w_\mathcal{V} = P_\mathcal{V}w \) for \( w \in \mathbb{R}^n \) and \( D_\mathcal{V} = D P_\mathcal{V} \) for a linear operator \( D \).

\(^4\)For some operators \( \Phi \) drawn from some appropriate random ensembles, one can show, using , that sample complexity bounds in [10, 36] are sufficient for sharpness to hold with high probability.
4.1 Subdifferential decomposability

The following definition taken from [40, Definition 3] is instrumental in our study.

**Definition 4.1** (Model Tangent Subspace). Denote the model vector $e$ of $J_0$ at $u_0 \triangleq D^*x_0$ is the projection of 0 onto the affine hull of $\partial J_0(u_0)$

$$e \triangleq P_{\text{aff}(\partial J_0(u_0))}(0).$$  \hfill (4.2)

The model tangent subspace $T$ at $u_0$ associated to $J_0$ is defined by

$$T \triangleq S^\perp \text{ where } S \triangleq \text{aff}(\partial J_0(u_0)) - e. \hfill (4.3)$$

Obviously, $e \in T$.

**Lemma 4.2** (Decomposability, [40, Theorem 1]). Let $u_0 \in \mathbb{R}^n \setminus \{0\}$ and $v_0$ be a vector in $\text{ri} \partial J_0(u_0)$. Then

$$\partial J_0(u_0) = \{v \in \mathbb{R}^n | v_T = e, \gamma_C(P_S(v - v_0)) \leq 1\}, \hfill (4.4)$$

where $C \triangleq \partial J_0(u_0) - v_0$ and $\gamma_C$ is the gauge function of $C$ defined in (2.7). Moreover $v \in \text{ri} \partial J_0(u_0)$ if and only if $v_T = e$ and $\gamma_C(P_S(v - v_0)) < 1$.

We then have the following necessary and sufficient optimality condition for problem (1.2).

**Lemma 4.3.** $x_0$ is an optimal solution to problem (1.2) with $J$ in (4.1) if and only if there exists $v \in \mathbb{R}^p$ such that

$$v_T = e, \gamma_C(v_S - P_Sv_0) \leq 1, \text{ and } Dv \in \text{Im} \Phi^*.$$ \hfill (4.5)

**Proof.** Combine (3.6) and Lemma 4.2. \hfill \Box

4.2 Quantitative characterization of sharp minima

We start by providing a quantitative condition for checking optimality.

**Proposition 4.4** (Quantitative characterization of optimality). $x_0$ is an optimal solution to problem (1.2) with $J$ in (4.1) if and only if the following two conditions are satisfied

$$ND_S(ND_S)^\dagger ND_T e = ND_T e \hfill (4.6)$$

and

$$\rho(e) \triangleq \min_{u \in \text{Ker} ND_S} \gamma_C(-(ND_S)^\dagger ND_T e - P_Sv_0 + u) \leq 1, \hfill (4.7)$$

where $N$ is a matrix satisfying $\text{Ker} N = \text{Im} \Phi^*$ and $\text{Ker} N^* = \{0\}$. The minimum in (4.7) is well-defined and achieved at some $u \in \text{Ker} ND_S \cap S$.

**Proof.** Suppose that $x_0$ is a solution to (1.2). It follows from Lemma 4.3 that there exists $v \in \mathbb{R}^p$ such that

$$0 = NDv = N(D_T e + D_Sv_S) \implies ND_Sv_S = -ND_T e.$$  

This is equivalent, via (2.2), to

$$ND_S(ND_S)^\dagger ND_T e = ND_T e \hfill \text{ and } v_S \in -(ND_S)^\dagger ND_T e + \text{Ker} ND_S.$$  

This tells us, using again Lemma 4.3, that

$$\rho(e) \leq \gamma_C(v_S - P_Sv_0) \leq 1,$$
which proves the necessary part.

Conversely, suppose that both (4.6) and (4.7) hold. Let \( u^* \in \text{Ker} \, ND_S \) be a minimizer to (4.7). Since \( \text{dom} \, \gamma_C = S \) and \( \gamma_C \) is coercive on \( S \) by [40, Proposition 2], \( u^* \) exists and belongs to \( S \).

Define \( \bar{u} \stackrel{\text{def}}{=} -(ND_S)^\dagger ND_e + u^* \). This vector verifies

\[
\gamma_C(\bar{u} - P_S v_0) = \rho(e) \leq 1. \tag{4.8}
\]

Since \( 0 \in \text{ri} \, C \subset C \), and in view of (4.8), we infer that \( \bar{u} - P_S v_0 \in C \subset S \). This implies \( \bar{u} \in S \). Note further from (4.6) that

\[
ND(e + \bar{u}) = ND(e + P_S \bar{u}) = ND_T e - ND_S (ND_S)^\dagger ND_T e = 0,
\]

which means \( D(e + \bar{u}) \in \text{Im} \Phi^* \). Altogether, the vector \( e + \bar{u} \) verifies the properties (4.5) in Lemma 4.3 whence we deduce that \( x_0 \) is an optimal solution to problem (1.2). The proof is complete. \( \square \)

Equation (4.6) means that the linear system

\[
ND_S v = -ND_T e
\]

is consistent. When \( D = I \), Lemma 4.3 and Proposition 4.4 tell us that conditions (4.6)-(4.7) are equivalent to the so-called Source Condition well-known in inverse problems (see [34, 19, 39, 42] and references therein). We call \( \rho(e) \) the Source Coefficient. Under condition (4.6), \( \rho(e) \) is indeed the optimal value to the following problem

\[
\min_{v \in \mathbb{R}^p} \gamma_C(v - P_S v_0) \quad \text{subject to} \quad ND_S v = -ND_T e,
\]

which is equivalent to the following convex optimization problem

\[
\min_{v \in \mathbb{R}^p} \gamma_C(v - P_S v_0) \quad \text{subject to} \quad ND v = -ND_T e \quad \text{and} \quad v \in S. \tag{4.9}
\]

**Remark 4.5** (Computing the Source Coefficient \( \rho(e) \) for decomposable norms). One important class of regularizers is \( f(x) = \|D^* x\|_A \), where \( J_0(\cdot) = \| \cdot \|_A \) is a decomposable norm in \( \mathbb{R}^p \). The class of decomposable norms is introduced in [26, 7] and was generalized in [40] (coined strong gauges there). This class includes the \( \ell_1 \) norm, the \( \ell_1/\ell_2 \) norm, the nuclear norm but not the \( \ell_\infty \) norm. According to [7], a norm \( \| \cdot \|_A \) is called decomposable at \( u_0 \stackrel{\text{def}}{=} D^* x_0 \) if there is a subspace \( V \subset \mathbb{R}^p \) and a vector \( e_0 \in V \) such that

\[
\partial \|u_0\|_A = \{ v \in \mathbb{R}^p | \ v_V = e_0 \quad \text{and} \quad \|v\|_A^* \leq 1 \}, \tag{4.10}
\]

where \( \| \cdot \|_A^* \) is the dual norm to \( \| \cdot \|_A \). From [40, Proposition 7], it follows that (4.10) complies with Lemma 4.2 by taking \( V = T = S^\perp = (\text{aff}(\partial J_0(u_0)) - e)^\perp \), \( v_0 = e \in ri \partial \|u_0\|_A \), in which case \( C = \partial \|u_0\|_A - v_0 = \{ v \in S | \|v\|_A \leq 1 \} \) and thus for any \( v \in S \)

\[
\gamma_C(v) = \|v\|_A^*.
\]

Hence, problem (4.9) simplifies to

\[
\min_{v \in \mathbb{R}^p} \|v\|_A^* \quad \text{subject to} \quad ND v = -ND_T e \quad \text{and} \quad v \in S. \tag{4.11}
\]

The matrix \( N \) can be chosen from the singular value decomposition of \( \Phi = USV^* \) as \( N = V_G^* \), where \( V_G \) is the submatrix of \( V \) whose columns are indexed by \( G = \{ r + 1, r + 2, \ldots , n \} \) with \( r = \text{rank} \, \Phi \). This idea is slightly inspired from [25, 44] for the case where \( \| \cdot \|_A \) is the \( \ell_1 \) norm. We will return in Section 5 to discussing further the use of the Source Coefficient to classify sharp and strong/unique solutions for the group-sparsity regularization.
We are now in position to state the main result of this section, which provides equivalent characterizations of sharp minima.

**Theorem 4.6** (Characterizations of sharp solutions). Consider J in (4.1). The following statements are equivalent:

(i) \( x_0 \) is a sharp solution to problem (1.2).

(ii) The following Restricted Injectivity holds at \( x_0 \)

\[
\text{Ker } \Phi \cap \text{Ker } D_{x_0}^* = \{0\}
\]

(4.12)

and the Source Coefficient \( \rho(e) < 1 \).

(iii) The Restricted Injectivity (4.12) holds and the Nondegenerate Source Condition is satisfied at \( x_0 \) in the sense that

\[
\exists v \in \mathbb{R}^p \text{ such that } Dv \in \text{Im } \Phi^* \text{ and } v \in \text{ri} \partial J_0(x_0).
\]

Moreover, the sharpness constant \( c \) at \( x_0 \) can be as large as

\[
c = (1 - \rho(e))sc_1 > 0 \quad \text{with} \quad c_1 \overset{\text{def}}{=} \min_{w \in \text{Ker } \Phi \cap S^{n-1}} \|D_{x_0}^*w\| > 0
\]

and \( s > 0 \) satisfying \( B_s(0) \cap S \subset C \).

**Proof.** \[(i) \Rightarrow (ii)\]. Suppose that \( x_0 \) is a sharp solution to (1.2). From Lemma 2.4(i), this is equivalent to the existence of some \( c > 0 \) such that \( d\Psi(x_0)(w) \geq c\|w\| \) for all \( w \in \mathbb{R}^n \). From (3.6) and Lemma 4.2, we have

\[
d\Psi(x_0)(w) = dJ(x_0)(w) + i_{\text{Ker } \Phi}(w)
\]

\[
= dJ_0(D^*x_0)(D^*w) + i_{\text{Ker } \Phi}(w)
\]

\[
= \sigma_{\partial J_0(D^*x_0)}(D^*w) + i_{\text{Ker } \Phi}(w)
\]

\[
= \sup \{ \langle v, D^*w \rangle \mid v_T = e, v_S \in P_Sv_0 + C \} + i_{\text{Ker } \Phi}(w)
\]

\[
= \langle e, D_T^*w \rangle + \langle P_Sv_0, D_S^*w \rangle + \sup_{z \in C} \langle z, D_S^*w \rangle + i_{\text{Ker } \Phi}(w)
\]

\[
= \langle e, D_T^*w \rangle + \langle P_Sv_0, D_S^*w \rangle + c_1(D_S^*w) + i_{\text{Ker } \Phi}(w).
\]

(4.15)

For any \( w = N^*u \in \text{Ker } \Phi \), we obtain from (4.15), the inequality \( d\Psi(x_0)(w) \geq c\|w\| \), and (4.6) that

\[
\sigma_C(D_S^*w) - c\|w\| \geq -\langle e, D_T^*N^*u \rangle - \langle P_Sv_0, D_S^*N^*u \rangle
\]

\[
= -\langle ND_Te, u \rangle - \langle P_Sv_0, D_S^*N^*u \rangle
\]

\[
= -\langle (ND_S)(ND_S)^*ND_Te, u \rangle - \langle P_Sv_0, D_S^*N^*u \rangle
\]

\[
= -\langle (ND_S)^*ND_Te + P_Sv_0, D_S^*w \rangle.
\]

(4.16)

If \( w \in \text{Ker } \Phi \cap \text{Ker } D_{x_0}^* \), we deduce from (4.16) that \(-c\|w\| \geq 0 \), which means \( w = 0 \). Thus the Restricted Injectivity (4.12) is satisfied.

Moreover, as \( J_0 \) is a continuous convex function, \( \partial J_0(D^*x_0) \) is compact, and so is \( C \), whence it follows that

\[
\sigma_C(D_S^*w) \leq r\|D_S^*w\| \leq r\|D_S^*\|\|w\| \quad \text{with} \quad r \overset{\text{def}}{=} \max \{\|z\| \mid z \in C\}.
\]

21
Combining the latter with (4.16) tells us that for any $v \in \text{Im} \, D_S^* N^*$,
\[
\left\langle (ND_S)^T ND_T e + P_S v_0, v \right\rangle \leq \left( 1 - \frac{c}{r \|D_S^*\|} \right) \sigma_C(v).
\]  
(4.17)

Let $C^o$ be the polar set of $C$ as defined in (2.9), and set $K \overset{\text{def}}{=} C^o \cap S$. $K$ is a non-empty closed convex set. Since $0 \in \text{ri} \, C$, there exists $s > 0$ such that and $B_s(0) \cap S \subset C$. For any $v \in K \setminus \{0\}$, we have $s \frac{v}{\|v\|} \in B_s(0) \cap S$ and thus, using (2.9), $\left\langle v, s \frac{v}{\|v\|} \right\rangle \leq \partial_{B_s(0) \cap S}(v) \leq \sigma_C(v) \leq 1$ since $v \in C^o$. It follows that $\|v\| \leq \frac{1}{s}$. Hence, $K$ is a compact set.

Let us bound from below the right hand side of (4.17). First, we have by Fenchel-Moreau theorem and the minimax theorem [30, Corollary 37.3.2] (since $K$ is compact), that
\[
\max_{v \in K \cap \text{Im} \, D_S^* N^*} \left\langle -(ND_S)^T ND_T e - P_S v_0, v \right\rangle = \max_{v \in K} \inf_{v \in \text{Ker} \, ND_S} \left\langle -(ND_S)^T ND_T e - P_S v_0 + z, v \right\rangle
\]
\[
= \max_{v \in K} \inf_{z \in \text{Ker} \, ND_S} \left\langle -(ND_S)^T ND_T e - P_S v_0 + z, v \right\rangle
\]
\[
= \min_{z \in \text{Ker} \, ND_S} \max_{v \in K} \left\langle -(ND_S)^T ND_T e - P_S v_0 + z, v \right\rangle
\]
\[
= \min_{z \in \text{Ker} \, ND_S} \sigma_K(-(ND_S)^T ND_T e - P_S v_0 + z).
\]  
(4.18)

On the other hand, for any $v \in K \cap \text{Im} \, D_S^* N^* \subset C^o$, we have $\sigma_C(v) \leq 1$ (see (2.9)). Let $v^* \in K \cap \text{Im} \, D_S^* N^*$ be a maximizer of the left hand side of (4.18). We then have from (4.17) and (4.18) that
\[
0 \leq \min_{z \in \text{Ker} \, ND_S} \sigma_K(-(ND_S)^T ND_T e - P_S v_0 + z) = -\left\langle (ND_S)^T ND_T e + P_S v_0, v^* \right\rangle
\]
\[
\leq \left( 1 - \frac{c}{r \|D_S^*\|} \right) \sigma_C(v^*) \leq 1 - \frac{c}{r \|D_S^*\|} < 1.
\]  
(4.19)

It remains now to compute $\sigma_K$. We have from Fenchel-Moreau theorem, [30, Corollary 16.4.1], standard conjugacy calculus and (2.10), that
\[
\sigma_K = (\iota_C + \iota_S)^* = \text{cl} \left( \inf_{\eta \in \mathbb{R}^p} \sigma_C(\cdot + \eta) + \sigma_S(\eta) \right) = \text{cl} \left( \inf_{\eta \in \mathbb{T}} \sigma_C(\cdot + \eta) \right) = \text{cl} \left( \inf_{\eta \in \mathbb{T}} \gamma_C(\cdot + \eta) \right).
\]

Since $\text{dom} \, \gamma_C = S$ by [40, Propopsition 2], we have for any $z \in \mathbb{R}^p$ that
\[
\inf_{\eta \in \mathbb{T}} \gamma_C(z + \eta) = \inf_{\eta \in \mathbb{T}} \gamma_C(P_S z + \eta) = \gamma_C(P_S z).
\]

Thus, the closure operation can be omitted above to get for any $z \in S$
\[
\sigma_K(z) = \gamma_C(z).
\]

Inserting this into (4.19), we get (ii), after observing that $\text{Im} \, (ND_S)^T = \text{Im} \, D_S^* N^* \subset S$ and that the minimum in $\rho(e)$ is achieved on $S$ (see Proposition 4.4).

[(ii)⇒(iii)]. Let $u^* \in S$ be a solution of the minimization problem in (4.7), denote $\bar{u} = -(ND_S)^T ND e + u^* \in S$ and $\bar{v} = e + \bar{u}$. We have $\bar{v}_T = e$ and, since (ii) is satisfied, $\gamma_C(\bar{v}_S - P_S v_0) < \frac{\gamma_C(v^* - P_S v_0)}{1 - \frac{c}{r \|D_S^*\|}}$, hence $\sigma_K(\bar{v}) = \gamma_C(\bar{v}) < 1$.
1. This is equivalent to \( \vartheta \in \text{ri} \partial J(x_0) \) thanks to the last claim of Lemma 4.2. It remains to show that \( D\vartheta \in \text{Im} \Phi^* \). As the Restricted Injectivity condition (4.12) holds,

\[
ND_S(ND_S)^\dagger ND_Te = ND_S(ND_S)^*(ND_S(ND_S)^*)^{-1}ND_Te = ND_Te,
\]

which verifies (4.6). (4.7) is also verified as shown above and we can then argue as in the proof of the sufficient part in Proposition 4.4 to deduce that \( D\vartheta \in \text{Im} \Phi^* \).

[(iii) \Rightarrow (i)]. Suppose that the Restricted Injectivity (4.12) holds at \( x_0 \) and there exists \( Dv \in \text{Im} \Phi^* \) and \( v \in \text{ri} \partial J(x_0) \). Hence, \( v_T = e \) and \( \gamma_C(P_S(v - v_0)) < 1 \) thanks to Lemma 4.2. Thus, for any \( w \in \text{Ker} \Phi \), we get from (4.15) that

\[
d\Psi(x_0)(w) = \langle e, D^*w \rangle + \langle P_Sv_0, D^*_sw \rangle + \sigma_C(D^*_sw)
\]

\[
= \langle v - P_Sv, D^*w \rangle + \langle P_Sv_0, D^*_sw \rangle + \sigma_C(D^*_sw)
\]

\[
= \langle -P_Sv, D^*w \rangle + \langle P_Sv_0, D^*_sw \rangle + \sigma_C(D^*_sw)
\]

\[
= \langle -P_S(v - v_0), D^*_sw \rangle + \sigma_C(P_Sw)
\]

\[
\geq -\sigma_C(D^*_sw)\gamma_C(P_S(v - v_0)) + \sigma_C(D^*_sw)
\]

\[
= \left( 1 - \gamma_C(P_S(v - v_0)) \right) \sigma_C(D^*_sw),
\]

where in the last two inequalities, we used the duality inequality on \( \text{dom} \sigma_C \times \text{dom} \gamma_C = \mathbb{R}^p \times \text{dom} S \). Recall that \( 0 \in \text{ri} C \) and \( B_s(0) \cap S \subset C \) for some \( s > 0 \). As \( D^*_sw \in S \), we have

\[
\sigma_C(D^*_sw) \geq \left\langle D^*_sw, s \frac{D^*_sw}{\|D^*_sw\|} \right\rangle = s\|D^*_sw\| \geq s_1\|w\|,
\]

where \( c_1 \overset{\text{def}}{=} \min \{ \|D^*_sw\| \mid w \in S^{n-1} \cap \text{Ker} \Phi \} \), and \( c_1 > 0 \) by virtue of the Restricted Injectivity (4.12). We derive from (4.20) that

\[
d\Psi(x_0)(w) \geq \left( 1 - \gamma_C(P_S(v - v_0)) \right) s_1\|w\| \quad \text{for all} \quad w \in \text{Ker} \Phi,
\]

which verifies (i) by Lemma 2.4. Recall that \( Dv \in \text{Im} \Phi^* \) and \( v_T = e \), and thus \( NDv_S = ND_Te \), which in turn shows that the vector \( v_S \) obeys the constraint in (4.9), and thus \( \rho(e) \leq \gamma_C(P_S(v - v_0)) < 1 \). The sharpness constant of \( \Psi \) can then be as large as devised in (4.14). The proof is complete.

**Corollary 4.7 (Sufficient condition for sharp solution).** If the Restricted Injectivity holds at \( x_0 \) and the following condition

\[
\tau(e) \overset{\text{def}}{=} \gamma_C(-(ND_S)^\dagger ND e - P_Sv_0) < 1
\]

is satisfied, then \( x_0 \) is a sharp solution to problem (1.2).

**Proof.** It is easy to see that \( \tau(e) \geq \rho(e) \). The result follows from Theorem 4.6. \( \square \)

**Remark 4.8.** The Restricted Injectivity (4.12) was proposed in [14, 39, 40, 42]. It also has tracks in some special cases, e.g., for the \( \ell_1 \) norm problems [16, 17, 19, 25, 41, 45, 44], \( \ell_1/\ell_2 \) norm problems [18, 21], and nuclear norm problems [10, 8, 7]. The form of the Nondegenerate Source Condition in Theorem 4.6 appears also in [39, 40, 42]. It generalizes the condition in [19] for the \( \ell_1 \) problem, which actually occurred earlier in [9]. The combination of Restricted Injectivity and Nondegenerate Source Condition in the above result are proved in [39, Theorem 5.3] as sufficient conditions for solution uniqueness to problem (1.2), but they are not necessary in general. By revisiting Example 3.9, we see that \( x_0 \) is a unique solution to problem (3.16)
but the Nondegenerate Source Condition is not satisfied. Indeed, the only vector \( v \in \mathbb{R}^2 \) satisfying \( \Phi^*v = (v_1 + v_2, v_1, -v_2) \in \partial f(x_0) = \{ (0, 1) \times [-1, 1] \} \) is \( v = (1, -1) \), but \( \Phi^*v = (0, 1, 1) \notin \text{ri} \partial f(x_0) \).

Theorem 4.6 strengthens [40, Corollary 1] by showing Restricted Injectivity and Nondegenerate Source Condition are necessary and sufficient for sharp minima. In the case of \( \ell_1 \) problem, our result recovers part of [44, Theorem 2.1] that gives a characterization for solution uniqueness, which is equivalent to sharp minima in this framework. Some other characterizations are also studied recently in [17, 24] by exploiting polyhedral structures. It is worth emphasizing that our result does not need polyhedrality. Our proof mainly relies on the well-known first-order condition in Lemma 2.4 for sharp minima and the subdifferential decomposability (4.4). Theorem 4.6 also covers many results about solution uniqueness in [10, 8, 7, 9, 16, 18, 17, 19, 21, 25, 33, 41, 37, 38, 45, 44].

**Remark 4.9.** The idea of using first-order analysis to study solution uniqueness to regularized optimization problems is not new as discussed above. For instance, the Null Space Property has been shown to ensure solution uniqueness for \( \ell_1 \) regularization [12, 25]. A generalization of this condition beyond the \( \ell_1 \) norm, coined Strong Null Space Property, was proposed in [14, 39, 40]. This property reads

\[
- \langle e, D_I^*w \rangle - \langle P_S v_0, D_S^*w \rangle < \sigma_C(D_S^*w) \quad \text{for all} \quad w \in \text{Ker} \Phi \setminus \{0\}.
\] (4.22)

It is immediate to see from (4.16) that sharpness at \( x_0 \) entails (4.22).

**The case of analysis \( \ell_1 \)** When \( \| \cdot \|_A = \| \cdot \|_1 \), the model vector \( e \) in (4.2) is indeed (sign \( (D_I^*x_0), 0_K) \), where \( I \equiv \supp (D^*x_0) \equiv \{ i \in \{1, 2, \ldots, p\} \mid (D^*x_0)_i \neq 0 \} \), \( K \equiv \{1, \ldots, p\} \setminus I \), and \( D_I \) is the submatrix of \( D \) with column indices \( I \). In his case, inequality (4.21) takes the form

\[
\tau(\text{sign} (D_I^*x_0)) = \| (ND_K)^+ ND_I \text{sign} (D_I^*x_0)\|_{\infty} < 1,
\]

which is called the **Analysis Exact Recovery Condition** in [25]. Another criterion used in [41] to check solution uniqueness for \( \ell_1 \) problem is the so-called **Analysis Identifiability Criterion** at sign \( (D_I^*x_0) \) denoted by

\[
\text{IC}\left(\text{sign} (D_I^*x_0)\right) \equiv \min_{v \in \text{Ker} D_I} \| D_K^+(\Phi^*\Phi_U)U^* - \mathbb{I} \| D_I \text{sign} (D_I^*x_0) - v\|_{\infty} < 1,
\] (4.23)

where \( U \) is basis of \( \text{Ker} D_I^* \) and \( \Phi_U \equiv \Phi U \). This condition reduces to the synthesis one introduced in [16] in the case of \( D^* = \mathbb{I} \) while \( \tau(\text{sign} (D_I^*x_0)) \) does not. As discussed in [25, 41], \( \tau(\text{sign} (D_I^*x_0)) \) and \( \text{IC}(\text{sign} (D_I^*x_0)) \) are different and no one implies the other even for the case \( D = \mathbb{I} \).

For our general framework with \( J \) as in (4.1), the Analysis Identifiability Criterion is satisfied at \( x_0 \) if

\[
\text{IC}(e) \equiv \min_{u \in \text{Ker} D_S} \gamma_C(D_S^+(\Phi^*\Phi_U)U^* - \mathbb{I})D_T e - P_S v_0 + u < 1,
\] (4.24)

where \( U \) is a matrix whose columns form a basis of \( \text{Ker} D_S^* \) and \( \Phi_U \equiv \Phi U \).

**Proposition 4.10.** If the Restricted Injectivity (4.12) holds at \( x_0 \) then \( \rho(e) \leq \text{IC}(e) \). Consequently, if the Analysis Identifiability Criterion holds at \( x_0 \), then \( x_0 \) is a sharp solution to (1.2).

**Proof.** (4.12) means that \( \text{Ker} \Phi_U = \{0\} \) and \( \Phi_U = (\Phi^*_U \Phi_U)^{-1} \Phi^*_U \). Let \( \bar{u} \in \text{Ker} D_S \) be a minimizer of problem (4.24), and define

\[
\bar{v} \equiv D_S^+(\Phi^*(\Phi_U^*)^*U^* - \mathbb{I})D_T \bar{e} + \bar{u} \quad \text{with} \quad \gamma_C(\bar{v} - P_S v_0) = \text{IC}(e).
\]
Note that
\[ U^*(\Phi^*(\Phi_U^*)^*U^* - I)D_Te = (\Phi_U^*(\Phi_U^*)^{-1}U^* - U^*)D_Te = 0. \]
It follows that \((\Phi^*(\Phi_U^*)^*U^* - I)D_Te \in \text{Im} D_S\), which implies that \(D_S\vartheta = (\Phi^*(\Phi_U^*)^*U^* - I)D_Te\) by (2.2). Hence we have
\[ ND_S\vartheta = (N\Phi^*(\Phi_U^*)^*U^* - N)D_Te = -ND_Te, \]
which implies that \(\vartheta \in -(ND_S)^\dagger ND_Te + \text{Ker} ND_S\) and thus \(\rho(e) \leq \gamma_C(\vartheta - P_Sv_0) = IC(e)\). When the Analysis Identifiability Criterion is satisfied at \(x_0\), we have \(\rho(e) \leq IC(e) < 1\) and thus \(x_0\) is a sharp solution to (1.2) due to Theorem 4.6. The proof is complete. \(\square\)

In plain words, Proposition 4.10 tells us that \(\rho(e) < 1\) is weaker than the Analysis Identifiability Criterion (4.24). In turn Theorem 4.6 is stronger than [41, Theorem 2] for the analysis \(\ell_1\) problem. It also covers the [39, Proposition 5.7]. For the analysis \(\ell_1\) problem, [44] provides an example where \(\rho(\text{sign}(D^*_1x_0))\) is strictly smaller than both \(\tau(\text{sign}(D^*_1x_0))\) and \(IC(\text{sign}(D^*_1x_0))\).

### 4.3 Robust recovery with analysis decomposable priors

The following result proves robust recovery with linear rate under Restricted Injectivity and Non-degenerate Source Condition.

**Corollary 4.11** (Robust recovery of decomposable norm minimization). Suppose that \(J_0\) is a nonnegative continuous convex function satisfying
\[ (D^*)^{-1}(\text{Ker}(J_0)_\infty) \cap \text{Ker} \Phi = \{0\}. \]
If (4.12)-(4.13) hold at \(x_0\), we have linear convergence rate for robust recovery as in (3.17) and (3.18).

**Proof.** From [2, Proposition 2.6.3] \(J_\infty(w) = (J_0)_\infty(D^*w)\) for any \(w \in \mathbb{R}^n\). Hence, condition (4.26) is exactly (3.2). We obtain the claim by combining Theorem 4.6 and Corollary 3.11. \(\square\)

The constant in \(O(\delta)\) can be made explicit. In particular the sharpness constant is given by (4.14). This reveals that the "distance" to nondegeneracy is naturally captured by the sharpness constant, which plays a crucial role. Thus, the less degenerate, the more robust is the recovery.

Corollary 4.11 covers parts of [14, Theorem 2] (see also [39, 42]), [19, Theorem 4.2], and [44, Theorem 2] for the case of (analysis or synthesis) \(\ell_1\) minimization problems. When \(D^*_1 = I\) and \(J_0(x) = \|x\|_{A_R}\), it also covers the results in [10] about robust recovery for the constrained problem (1.4).

### 4.4 Connections between unique/sharp/strong solutions in the noiseless case

When there is noise in observation (1.3), problem (1.5) is usually used to recover the original signal \(x_0\). Solution uniqueness to (1.5) is especially important for exact recovery [16, 41]. We show next that Restricted Injectivity and Nondegenerate Source Condition are sufficient for strong minima to problem (1.5), and they become necessary for the \(\ell_1\) problem. This result is true for a larger class of regularized problems taking the form
\[ \min_{x \in \mathbb{R}^n} \Theta(x) \overset{\text{def}}{=} f(\Phi x) + \mu f(x), \]
where \(\mu\) is a positive parameter and the loss function \(f : \mathbb{R}^n \to \mathbb{R}\) is an extended real-valued convex function satisfying the following two conditions:
(A) $f$ is twice continuously differentiable in $\text{int}(\text{dom } f)$.

(B) $\nabla f^2(x)$ is positive definite for all $x \in \text{int}(\text{dom } f)$, i.e., $f$ is strictly convex in the interior of its domain.

In (1.5), the function $f$ is $\frac{1}{2} \| \cdot - y \|^2$ which certainly satisfies the above two conditions. Moreover, the standing assumptions (A) and (B) for $f$ cover the important case of the Kullback-Leibler divergence:

$$f_{\text{KL}}(z) = \begin{cases} \sum_{i=1}^{m} y_i \log \frac{y_i}{z_i} + z_i - y_i & \text{if } z \in \mathbb{R}_+^m \\ +\infty & \text{if } z \in \mathbb{R}_+^m \setminus \mathbb{R}_+^{m+}, \end{cases} \quad (4.28)$$

where $y \in \mathbb{R}_+^m$ and $0 \log 0 = 0$. This offers a natural way to measure of similarity of two nonnegative vectors (e.g., two discrete distributions) and is broadly used in statistical/machine learning and signal processing.

In the following result, we provide the connections between unique/sharp/strong solutions for the two problems (1.2) and (4.27). Part (i) of this result could be obtained from [24, Proposition 3.2], but we still give a short proof as our assumptions on $f$ are slightly different, e.g., $f$ may not have full domain.

**Proposition 4.12** (Unique/sharp/strong solutions for problems (1.2) and (4.27)). Suppose that $\bar{x}$ is an optimal solution to problem (4.27) and $\Phi \bar{x} \in \text{int}(\text{dom } f)$. Then $\bar{x}$ is a solution to problem (1.2) with $x_0 = \bar{x}$. Moreover, the following statements hold:

(i) $\bar{x}$ is the unique solution to (4.27) if and only if it is the unique solution to (1.2).

(ii) If $\bar{x}$ is a sharp solution to (1.2) then it is a strong solution to problem (4.27).

(iii) If $\bar{x}$ is a strong solution to (4.27) then it is also a strong solution to (1.2).

**Proof.** For any $x \in \Phi^{-1}(\Phi \bar{x})$, we have

$$f(\Phi \bar{x}) + \mu J(x) = f(\Phi x) + \mu J(x) \geq f(\Phi \bar{x}) + \mu J(\bar{x}). \quad (4.29)$$

It follows that $\bar{x}$ is a solution to problem (1.2) with $y_0 = \Phi \bar{x}$.

(i) If $\bar{x}$ is the unique solution to problem (4.27), we have the strict inequality in (4.29) provided that $x \neq \bar{x}$, which shows that $\bar{x}$ is also the unique solution to problem (1.2). Assume now that $\bar{x}$ is the unique solution to (1.2). By contradiction, suppose that $\bar{x}$ is not the unique solution to (4.27). Since $\text{Argmin}(\Theta)$ is convex and $\Phi^{-1}(\text{int}(\text{dom } f))$ is an open set containing $\bar{x}$, there exists $r > 0$ such that $B_r(\bar{x}) \subset \Phi^{-1}(\text{int}(\text{dom } f))$ and $B_r(\bar{x}) \cap \text{Argmin}(\Theta) \neq \emptyset$, while the later is not the singleton $\{\bar{x}\}$. Choose $\tilde{x} \in B_r(\bar{x})$ with $\tilde{x} \neq \bar{x}$. We have $-\Phi^* \nabla f(\Phi \tilde{x}) \in \partial f(\tilde{x})$ and $-\Phi^* \nabla f(\Phi \bar{x}) \in \partial f(\bar{x})$. The monotonicity of the subdifferential tells us that

$$-\langle \nabla f(\Phi \tilde{x}) - \nabla f(\Phi \bar{x}), \Phi \tilde{x} - \Phi \bar{x} \rangle = -\langle \Phi^* \nabla f(\Phi \tilde{x}) - \Phi^* \nabla f(\Phi \bar{x}), \tilde{x} - \bar{x} \rangle \geq 0.$$ 

Convexity of $f$ entails the opposite inequality which shows that

$$\langle \nabla f(\Phi \tilde{x}) - \nabla f(\Phi \bar{x}), \Phi \tilde{x} - \Phi \bar{x} \rangle = 0.$$ 

26
Since $f$ is twice continuously differentiable in int(-dom $f$), we obtain from the mean-value theorem that
\[ \int_{0}^{1} \langle \nabla^2 f(\bar{x} + t(\bar{x} - \bar{x})) \rangle \Phi(\bar{x} - \bar{x}) \, dt = 0. \] (4.30)
Since the Hessian is positive definite and continuous on int(-dom $f$), there exists some $\tau > 0$ such that
\[ \langle \nabla^2 f(\bar{x} + t(\bar{x} - \bar{x})) \rangle 
\Phi(\bar{x} - \bar{x}) \rangle \geq \tau \| \Phi(\bar{x} - \bar{x}) \|^2 \]
for all $t \in [0, 1]$. Combining this with (4.30) implies that $\Phi \bar{x} = \Phi \bar{x}$. Using this together with the fact that both $\bar{x}$ and $\bar{x}$ are minimizers to (4.27), entails that $J(\bar{x}) = J(\bar{x})$. This contradicts uniqueness of $\bar{x}$ for (1.2).

(ii) Assume that $\bar{x}$ is a sharp solution to (1.2). By Proposition 3.8, we have
\[ \text{Ker} \Phi \cap \mathcal{C}_f(x_0) = \{0\} \] (4.31)
where we recall $\mathcal{C}_f(x_0)$ from (3.10). From the sum rule (2.17) and convexity of $J$, we have
\[ d^2 \Theta(\bar{x}|0)(w) = \langle \nabla^2 f(\Phi \bar{x}) \Phi w, \Phi w \rangle + \mu dJ(x_0)(w) \geq \langle \nabla^2 f(\Phi \bar{x}) \Phi w, \Phi w \rangle \] (4.32)
and from (2.15), dom $d^2 \Theta(\bar{x}|0) \subset \{w \in \mathbb{R}^n| d\Theta(\bar{x})(w) = 0\}$. We also have
\[ d\Theta(\bar{x})(w) = \langle \nabla f(\Phi \bar{x}), \Phi w \rangle + \mu dJ(x_0)(w). \]
It then follows that
\[ \text{dom} d^2 \Theta(\bar{x}|0) \subset \{w \in \mathbb{R}^n| \langle \nabla f(\Phi \bar{x}), \Phi w \rangle + \mu dJ(x_0)(w) = 0\}. \] (4.33)
To verify that $\bar{x}$ is a strong solution to problem (4.27) by using Lemma 2.4, we claim that
\[ \langle \nabla^2 f(\Phi \bar{x}) \Phi w, \Phi w \rangle > 0 \quad \text{for all} \quad w \in \text{dom} d^2 \Theta(\bar{x}|0) \setminus \{0\}. \] (4.34)
Suppose that $w \in \text{dom} d^2 \Theta(\bar{x}|0)$ satisfying $\langle \nabla^2 f(\Phi \bar{x}) \Phi w, \Phi w \rangle \leq 0$. Since $\nabla^2 f(\Phi \bar{x}) \succ 0$, we have $\Phi w = 0$. This together with (4.33) tells us that $w \in \text{Ker} \Phi \cap \mathcal{C}_f(x_0) = \{0\}$ by (4.31). Thus inequality (4.34) holds and $\bar{x}$ is a strong solution to problem (4.27).

(iii) Suppose that $\bar{x}$ is a strong solution to problem (4.27). There exist constants $\kappa, \gamma > 0$ such that
\[ f(\Phi x) + \mu J(x) \geq f(\Phi \bar{x}) + \mu J(\bar{x}) + \frac{\kappa}{2} \| x - \bar{x} \|^2 \quad \text{for all} \quad x \in \mathcal{B}_\gamma(\bar{x}). \]
For any $x \in \mathcal{B}_\gamma(\bar{x}) \cap \Phi^{-1}(\Phi \bar{x})$, we obtain that
\[ J(x) \geq J(\bar{x}) + \frac{\kappa}{2\mu} \| x - \bar{x} \|^2, \]
which means that $\bar{x}$ is also a strong solution to (1.2) as claimed.

For the special case (1.5) of (4.27), [14, Theorem 1] shows that if $\bar{x}$ is an optimal solution to (4.27) with $x_0 = \bar{x}$ and the Strong Null Space Property (4.22) holds at $\bar{x}$, $\bar{x}$ is the unique solution to (4.27). As Strong Null Space Property is a characterization for sharp minima to problem (1.2), Proposition 4.12 advances [14, Theorem 1] and [40, Theorem 3] with further information that $\bar{x}$ is a strong solution to (1.5).

Two natural questions arise from Proposition 4.12: are the converse statements of (ii)-(iii) true? That is:
(Q.1) If $\bar{x}$ is a strong solution to (4.27), can it be a sharp solution to (1.2) with $x_0 = \bar{x}$?

(Q.2) If $\bar{x}$ is a strong solution to (1.2), can it be a strong solution to (4.27)?

For analysis $\ell_1$ problems, i.e., $f_0(\cdot) = \| \cdot \|_1$, and more generally for $f_0$ the support function of any polyhedral convex compact $C$ such that $0 \in \text{ri}C$, we have positive answers for both questions.

**Corollary 4.13** (Solution uniqueness to $\ell_1$ problems). Let $\bar{x}$ be a minimizer to (4.27) with $f_0(\cdot) = \| \cdot \|_1$. Then the following are equivalent:

(i) $\bar{x}$ is the unique solution to problem (1.2) with $x_0 = \bar{x}$.

(ii) $\bar{x}$ is the sharp solution to problem (1.2) with $x_0 = \bar{x}$.

(iii) $\bar{x}$ is the unique solution to problem (4.27).

(iv) $\bar{x}$ is the strong solution to problem (4.27).

**Proof.** [(i)\(\iff\)(iii)] and [(ii)\(\implies\)(iv)] are from Proposition 4.12. [(iv)\(\implies\)(iii)] is trivial. Finally, [(i)\(\iff\)(ii)] follows by combining Proposition 3.4 and Proposition 3.8(i) since $f_0$ is a polyhedral norm, in which case the descent and critical cones coincide at any $x_0$ (see Proposition 3.7).

According to Theorem 4.6, conditions $\text{Ker } \Phi \cap \text{Ker } D_\Phi^* = \{0\}$ and $\rho(e) < 1$ form a characterization for solution uniqueness to $\ell_1$ problem. A similar result was established in [44, Theorem 1] for problems (1.2) and (1.5) with the extra assumption that $\Phi$ has full row-rank. Corollary 4.13 is more general and reveals that the unique solution to problem (4.27) is the strong solution.

The answer is negative for (Q.1) in general; see our Theorem 5.12 and Example 3.9. Regarding (Q.2), we do have a positive answer for group-sparsity; see Theorem 5.3 and Theorem 5.12. However, it is not true for the nuclear norm minimization problem as we now show.

**Example 4.14** (Strong solutions of (1.2) are not those of (4.27)). Let us consider the following nuclear norm minimization problem

$$\min_{X \in \mathbb{R}^{2 \times 2}} \Theta(X) \overset{\text{def}}{=} \frac{1}{2}\|Y - \Phi(X)\|^2 + \|X\|_*,$$  \hspace{1cm} (4.35)

where $\| \cdot \|_*$ stands for the nuclear norm of $X$, and $\Phi : \mathbb{R}^{2 \times 2} \to \mathbb{R}^2$ is the diagonal operator, i.e., $\Phi(X) = (X_{11}, X_{22})^\top$ and $Y = (2, 1)^\top$. This is a special case of (4.27) with $f(\cdot) = \frac{1}{2}\|Y - \cdot\|^2$. Let $\bar{X} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

We have

$$\Phi^* \nabla f(\Phi(\bar{X})) = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \quad \text{and} \quad \partial \|\bar{X}\|_* = \left\{ \begin{pmatrix} 1 & 0 \\ 0 & \alpha \end{pmatrix} \mid \alpha \in [-1, 1] \right\}.$$

Thus $0 \in \partial \Theta(\bar{X})$, i.e., $\bar{X}$ is a solution to (4.35). By Proposition 4.12, it is also a solution to

$$\min_{X \in \mathbb{R}^{2 \times 2}} \|X\|_* \quad \text{and} \quad \Phi(X) = (1, 0)^\top.$$

(4.36)

For any $2 \times 2$ matrix $X$, let $\sigma_1, \sigma_2$ be its singular values. We have

$$\|X\|_* = \sigma_1 + \sigma_2 = \sqrt{\sigma_1^2 + \sigma_2^2 + 2\sigma_1\sigma_2} = \sqrt{\|X\|^2_2 + 2|\text{det}(X)|}.$$ \hspace{1cm} (4.37)

The feasible set of (4.36) consists of matrices of the form $X = \begin{pmatrix} 1 & a \\ b & 0 \end{pmatrix}$, and we obtain from (4.37) that

$$\|X\|_* = \sqrt{1 + (|a| + |b|)^2}.$$
Thus $X$ is the unique solution to (4.36) as well as (4.35) due to Proposition 4.12 again. Next we claim that $X$ is the strong solution to (4.36), which means there exist $\kappa, \delta > 0$ such that

$$\|X\|_* - \|X\|_* \geq \frac{\kappa}{2} \|X - \bar{X}\|_F^2 \quad \text{for all} \quad X = \begin{pmatrix} 1 & a \\ b & 0 \end{pmatrix} \quad \text{with} \quad \|X - \bar{X}\|_F = \sqrt{a^2 + b^2} \leq \delta. \quad (4.38)$$

Indeed, we have

$$\|X\|_* - \|X\|_* = \sqrt{1 + (|a| + |b|)^2} - 1 = \frac{a^2 + b^2 + 2|ab|}{\sqrt{1 + a^2 + b^2 + 2|ab|} + 1} \geq \frac{a^2 + b^2}{\sqrt{1 + 2\delta^2 + 1}} = \frac{1}{\sqrt{1 + 2\delta^2 + 1}} \|X - \bar{X}\|_F^2.$$ 

This certainly verifies (4.38). Next we claim that $X$ is not a strong solution to (4.35). Pick $X_\varepsilon \overset{\text{def}}{=} \begin{pmatrix} 1 + \varepsilon^2 & \varepsilon \\ \varepsilon & \varepsilon^2 \end{pmatrix}$ with $\varepsilon > 0$ sufficiently small, observe that $\|X - \bar{X}\|_F^2 = 2(\varepsilon^2 + \varepsilon^4)$. It follows from (4.37) that

$$\Theta(X_\varepsilon) - \Theta(X) = \frac{1}{2} \left\| \begin{pmatrix} \varepsilon^2 - 1 \\ \varepsilon^2 - 1 \end{pmatrix} \right\|^2 + \left\| \begin{pmatrix} 1 + \varepsilon^2 & \varepsilon \\ \varepsilon & \varepsilon^2 \end{pmatrix} \right\|_*^2 - 2 = (\varepsilon^2 - 1)^2 + \sqrt{((1 + \varepsilon^2)^2 + 2\varepsilon^2 + \varepsilon^4) + 2\varepsilon^4} - 2 = (\varepsilon^2 - 1)^2 + (1 + 2\varepsilon^2) - 2 = \varepsilon^4.$$

Therefore, $X$ cannot be a strong solution to (4.35), which also implies that $X$ is neither a sharp solution to (4.35) nor to (4.36) due to Proposition 4.12.

5 Characterizations of unique/strong solutions for group-sparsity

In this section, we study the following particular case of (1.2), where $J_0$ is the $\ell_1 / \ell_2$ norm that promotes group sparsity [29, 33, 43].

$$\min_{x \in \mathbb{R}^p} \|D^*x\|_{\ell_1 / \ell_2} \quad \text{subject to} \quad \Phi x = \Phi x_0. \quad (5.1)$$

Following the notation in [7], we suppose that $\mathbb{R}^p$ is decomposed into $q$ groups by

$$\mathbb{R}^p = \bigoplus_{g=1}^q V_g, \quad (5.2)$$

where each $V_g$ is a subspace of $\mathbb{R}^p$ with the same dimension $G$. For any $u \in \mathbb{R}^p$, we write $u = \sum_{g=1}^q u_g$ with $u_g \in V_g$ being the vector in group $V_g$. The $\ell_1 / \ell_2$ norm in $\mathbb{R}^p$ is defined by

$$\|u\|_{\ell_1 / \ell_2} = \sum_{g=1}^q \|u_g\|.$$

29
Proof. Let us start by verifying the inclusion "⊂" in (5.7). Recall that $J(x) = \|D^*x\|_{\ell_1/\ell_2}$. For any $w \in \text{int} \ (C_f(x_0))$, we get from (3.10) that

$$dJ(x_0)(w) = \lim_{t \downarrow 0} \frac{J(x_0 + tw) - J(x_0)}{t} < 0.$$ 

Hence there is some $t_0 > 0$ such that $J(x_0 + t_0w) < J(x_0)$. This ensures $w \in D_f(x_0)$. For any $w \in E \cap \text{bd} C_f(x_0)$, we represent $D^*_Iw = \sum_{g \in I} \lambda_g (D^*_x)g$ with $\lambda_g \in \mathbb{R}$, $g \in I$ and

$$0 = \langle D_Ie, w \rangle + \|D^*_g w\|_{\ell_1/\ell_2} = \langle e, D^*_Iw \rangle + \|D^*_g w\|_{\ell_1/\ell_2} = \sum_{g \in I} \lambda_g \|D^*_x \| + \|D^*_g w\|_{\ell_1/\ell_2}. \quad (5.11)$$

Thus $\ell_1/\ell_2$ norm is decomposable at $\bar{u}$ as in Remark 4.5, where $T = \bigoplus_{g \in I} V_g$, $S = T^\perp$, and

$$e = \sum_{g \in I} \frac{u_g}{\|u_g\|}. \quad (5.6)$$

5.1 Descent cone of group sparsity

Sharp minima at $x_0$ for problem (5.1) is studied in our previous section. However, unlike the case of $\ell_1$ problem, a unique solution to problem (5.1) may be not sharp; see Example 3.9. To characterize the solution uniqueness to group sparsity problem (5.1), we compute the descent cone $D_f(x_0)$ in (3.8) as follows.

**Theorem 5.1** (Descent cone to $\ell_1/\ell_2$ problem and geometric characterization for solution uniqueness). The descent cone at $x_0$ to problem (5.1) is given by

$$D_f(x_0) = (E \cap \text{bd} C_f(x_0)) \cup (\text{int} C_f(x_0)), \quad (5.7)$$

where

$$E \eqdef \{ w \in \mathbb{R}^p \mid D^*_Iw \in \text{Im} \{ (D^*_x)g \mid g \in I \} \}, \quad (5.8)$$

and $\text{bd} C_f(x_0)$ stands for the boundary of the critical cone $C_f(x_0)$ defined in (3.10), i.e.,

$$\text{bd} C_f(x_0) = \{ w \in \mathbb{R}^p \mid \langle D_Ie, w \rangle + \|D^*_g w\|_{\ell_1/\ell_2} = 0 \}. \quad (5.9)$$

Consequently, $x_0$ is a unique solution to (5.1) if and only if

$$\text{Ker} \Phi \cap \left( (E \cap \text{bd} C_f(x_0)) \cup (\text{int} C_f(x_0)) \right) = \{0\}. \quad (5.10)$$

Proof. Let us start by verifying the inclusion "⊂" in (5.7). Recall that $J(x) = \|D^*x\|_{\ell_1/\ell_2}$. For any $w \in \text{int} (C_f(x_0))$, we get from (3.10) that

$$dJ(x_0)(w) = \lim_{t \downarrow 0} \frac{J(x_0 + tw) - J(x_0)}{t} < 0.$$ 

Hence there is some $t_0 > 0$ such that $J(x_0 + t_0w) < J(x_0)$. This ensures $w \in D_f(x_0)$. For any $w \in E \cap \text{bd} C_f(x_0)$, we represent $D^*_Iw = \sum_{g \in I} \lambda_g (D^*_x)g$ with $\lambda_g \in \mathbb{R}$, $g \in I$ and

$$0 = \langle D_Ie, w \rangle + \|D^*_g w\|_{\ell_1/\ell_2} = \langle e, D^*_Iw \rangle + \|D^*_g w\|_{\ell_1/\ell_2} = \sum_{g \in I} \lambda_g \|D^*_x \| + \|D^*_g w\|_{\ell_1/\ell_2}. \quad (5.11)$$
Define \( I_- \overset{\text{def}}{=} \{ g \in I \mid \lambda_g < 0 \} \). If \( I_- = \emptyset \), we get from (5.11) that \( D^*_g w = 0 \) and \( \lambda_g = 0 \) for all \( g \in I \), which implies that \( D^*_f w = 0 \) and thus \( D^* w = 0 \). Therefore, we get

\[
J(x_0 + w) = J_0(D^*(x_0 + w)) = J_0(D^* x_0) = J(x_0),
\]

which tells us that \( w \in D_f(x_0) \). If \( I_- \neq \emptyset \), define \( t_1 \overset{\text{def}}{=} \min \left\{ -\frac{1}{\lambda_g} \mid g \in I_- \right\} > 0 \), we obtain from (5.11) that

\[
J(x_0 + t_1 w) - J(x_0) = \| D^* x_0 + t_1 D^* w \|_{\ell_1/\ell_2} - \| D^* x_0 \|_{\ell_1/\ell_2} = \sum_{g \in I} (1 + t_1 \lambda_g) \| (D^* x_0)_g \| + t_1 \| D^*_g w \|_{\ell_1/\ell_2} - \| D^* x_0 \|_{\ell_1/\ell_2} = t_1 \left( \sum_{g \in I} \lambda_g \| (D^* x_0)_g \| + \| D^*_g w \|_{\ell_1/\ell_2} \right) + \sum_{g \in I} \lambda_g \| (D^* x_0)_g \| - \| D^* x_0 \|_{\ell_1/\ell_2}
\]

\[
= 0,
\]

where the third equality is from the choice of \( t_1 \). In both cases of \( I_- \), \( w \in D_f(x_0) \).

To justify the reverse inclusion “\( \subset \)” in (5.7), take any \( w \in D_f(x_0) \) and let \( t > 0 \) such that \( \| D^* x_0 + t D^* w \|_{\ell_1/\ell_2} \leq \| D^* x_0 \|_{\ell_1/\ell_2} \). For any \( \alpha \in (0, 1) \), we have

\[
\| D^* x_0 \|_{\ell_1/\ell_2} \geq \alpha \| D^* x_0 + t D^* w \|_{\ell_1/\ell_2} + (1 - \alpha) \| D^* x_0 \|_{\ell_1/\ell_2} \geq \| D^* x_0 + at D^* w \|_{\ell_1/\ell_2}.
\]

Choose \( \alpha > 0 \) sufficiently small such that

\[
\| (D^* x_0)_g + at(D^* w)_g \| > 0 \quad \text{for all} \quad g \in I.
\]

Since \( w \in D_f(x_0) \subset C_f(x_0) \) by (3.11), it suffices to show that if \( w \in \text{bd} C_f(x_0) \) then \( w \in \mathcal{E} \). Suppose that \( w \in \text{bd} C_f(x_0) \), we have

\[
0 = \langle D_T e, w \rangle + \| D^*_g w \|_{\ell_1/\ell_2} = \langle e, D^*_g w \rangle + \| D^*_g w \|_{\ell_1/\ell_2}.
\]

It follows from the latter and (5.12) that

\[
0 \geq \| D^* x_0 + at D^* w \|_{\ell_1/\ell_2} - \| D^* x_0 \|_{\ell_1/\ell_2} = \sum_{g \in I} \| (D^* x_0)_g + at(D^* w)_g \| + at \sum_{g \in K} \| (D^* w)_g \| - \| D^* x_0 \|_{\ell_1/\ell_2} = \sum_{g \in I} \left( \| (D^* x_0)_g + at(D^* w)_g \| - \| (D^* x_0)_g \| - at \langle e_g, (D^* w)_g \rangle \right).
\]

Since \( e_g = \partial \| (D^* x_0)_g \| \), each \( \| (D^* x_0)_g + at(D^* w)_g \| - \| (D^* x_0)_g \| - at \langle e_g, (D^* w)_g \rangle \geq 0 \) for \( g \in I \). This together with (5.13) tells us that

\[
0 = \| (D^* x_0)_g + at(D^* w)_g \| - \| (D^* x_0)_g \| - at \langle e_g, (D^* w)_g \rangle \quad \text{for all} \quad g \in I.
\]

Hence, we have

\[
0 = \| (D^* x_0)_g \| - \langle e_g, (D^* x_0)_g \rangle = \| (D^* x_0)_g + at(D^* w)_g \| - \langle e_g, (D^* x_0)_g + at(D^* w)_g \rangle.
\]
As $\|e_g\| = 1$ and $(D^*x_0)_g + at(D^*w)_g \neq 0$, the latter equality holds when

$$(D^*x_0)_g + at(D^*w)_g = \delta_g e_g$$

for some $\delta_g > 0$, $g \in I$. It follows that

$$(D^*w)_g = \frac{1}{a t}(\delta_g - \|(D^*x_0)_g\|)e_g$$

for any $g \in I$, which ensures that $w \in E$ and verifies the equality (5.7).

The characterization for solution uniqueness at $x_0$ in (5.10) follows directly from Proposition 3.4 and (5.7).

5.2 Unique vs strong solutions

We show next that a unique solution to (1.2) is indeed a strong solution. The proof is based on the second-order analysis in Lemma 2.4. We need the computation of the second subderivative for the function $\Psi$ defined in (3.3).

Lemma 5.2 (Second subderivative to $\ell_1/\ell_2$ norm). Suppose that $x_0$ is a minimizer to problem (5.1). Then we have

$$\text{dom } d^2\Psi(x_0|0) = \text{Ker } \Phi \cap \text{bd } C_1(x_0) \tag{5.14}$$

and

$$d^2\Psi(x_0|0)(w) = \sum_{g \in I} \frac{\|(D^*w)_g\|^2 \|(D^*x_0)_g\|^2 - \langle (D^*x_0)_g, (D^*w)_g \rangle^2}{\|(D^*x_0)_g\|^3} \text{ for } w \in \text{dom } d^2\Psi(x_0|0). \tag{5.15}$$

Proof. Since $x_0$ is an optimal solution to (5.1), we have $0 \in \partial \Psi(x_0)$. With $C = \Phi^{-1}(\Phi x_0)$, we have

$$d^2\Psi(x_0|0)(w) = \liminf_{t, w \to w} \frac{\|D^*(x_0 + tw)\|_{\ell_1/\ell_2} + \ell_C(x_0 + tw) - \|D^*x_0\|_{\ell_1/\ell_2} - \ell_C(x_0) - t\langle 0, w \rangle}{t^2}$$

$$= \liminf_{t, w \to w} \left( \frac{\|D^*(x_0 + tw)\|_{\ell_1/\ell_2} - \|D^*x_0\|_{\ell_1/\ell_2}}{t^2} + t\text{Ker } \Phi(w) \right).$$

It follows that $\text{dom } d^2\Psi(x_0|0) \subseteq \text{Ker } \Phi$. Since $D^*_Sx_0 = 0$, we have

$$\liminf_{t, w \to w} \frac{\|D^*(x_0 + tw)\|_{\ell_1/\ell_2} - \|D^*x_0\|_{\ell_1/\ell_2}}{t^2} = \liminf_{t, w \to w} \left( \frac{\|D^*_T(x_0 + tw)\|_{\ell_1/\ell_2} - \|D^*_Tx_0\|_{\ell_1/\ell_2} - t\langle De, w \rangle}{t^2} + \langle De, w \rangle + \|D^*_Sw\|_{\ell_1/\ell_2} \right). \tag{5.16}$$

Note that the Euclidean norm $\|u\|$ is twice differentiable at $u \neq 0$ with

$$\nabla \|u\| = \frac{u}{\|u\|} \quad \text{and} \quad \nabla^2 \|u\| = \frac{1}{\|u\|} \mathbb{I} - \frac{1}{\|u\|^3} uu^*.$$
This together with (2.16) tells us that
\[
\liminf_{t \downarrow 0, w' \rightarrow w'^*} \frac{\|D_T^+(x_0 + tw')\|_{\ell_1/\ell_2} - \|D_T^+x_0\|_{\ell_1/\ell_2} - t\langle De, w'\rangle}{\frac{1}{2}t^2} = \liminf_{t \downarrow 0, w' \rightarrow w'^*} \sum_{g \in I} \left(\|(D^*(x_0 + tw'))_g\| - \|(D^*x_0)_g\| - \frac{1}{2}\langle De, w'\rangle\right) = \sum_{g \in I} \frac{\|(D^*w)_g\|^2\|(D^*x_0)_g\|^2 - \|\langle D^*x_0, D^*w\rangle\|^2}{\|(D^*x_0)_g\|^3}.
\]

Since \(x_0\) is an optimal solution to (5.1), there exists \(z \in \mathbb{R}^p\) with \(P_Tz = e, \|P_Sz\|_{\ell_1/\ell_2} \leq 1\) and \(Dz \in \text{Im } \Phi^*\). For any \(w' \in \text{Ker } \Phi\), we have
\[
\langle De, w'\rangle = \langle D_Tz, w'\rangle = -\langle D_sz, w'\rangle = -\langle z, D_s^*w'\rangle.
\]

It follows that \(\langle De, w'\rangle + \|D_s^*w'\|_{\ell_1/\ell_2} \geq 0\). Hence we get
\[
\liminf_{t \downarrow 0, w' \rightarrow w'^*} \frac{\|D_s^*w'\|_{\ell_1/\ell_2}}{\frac{1}{2}t} = \begin{cases} 0 & \text{if } \langle De, w\rangle + \|D_s^*w\|_{\ell_1/\ell_2} = 0, w \in \text{Ker } \Phi, \\ \infty & \text{otherwise.} \end{cases}
\]

Since the “liminf” in (5.17) indeed becomes “lim”, the latter together with (5.17) and (5.16) verifies (5.14) and (5.15).

This calculation allows us to establish the main result in this section, which gives a quantitative characterization for unique/strong solutions to \(\ell_1/\ell_2\) problem (5.1).

**Theorem 5.3 (Characterizations for unique/strong solutions to \(\ell_1/\ell_2\) problems).** The following assertions are equivalent:

(i) \(x_0\) is a unique solution to problem (5.1).
(ii) \(x_0\) is a strong solution to problem (5.1).
(iii) \(x_0\) is a solution to (5.1), \(\text{Ker } \Phi \cap \mathcal{E} \cap \text{Ker } D_s^* = \{0\}\), and
\[
\zeta(e) \overset{\text{def}}{=} \min_{u \in \text{Ker } MD_s} \| (MD_s)^\dagger MD_T e - u \|_{\ell_1/\ell_2} < 1,
\]
where \(M^*\) is a matrix forming a basis matrix to \(\text{Ker } \Phi \cap \mathcal{E}\).

**Proof.** We first claim that \(x_0\) is a solution to (5.1) if and only if
\[
\text{Ker } \Phi \cap \text{int } (C_I(x_0)) = \emptyset.
\]
Indeed, \(x_0\) is a solution to (5.1) if and only if \(d\Psi(x_0)(w) \geq 0\) for all \(w \in \mathbb{R}^n\). Due to the computation of \(d\Psi(x_0)(w)\) in (4.15), \(d\Psi(x_0)(w) \geq 0\) means
\[
\langle De, w\rangle + \|D_s^*w\|_{\ell_1/\ell_2} \geq 0 \quad \text{for all } \quad w \in \text{Ker } \Phi,
\]
which is equivalent to (5.19).
Next let us verify the equivalence between (i) and (ii). By Theorem 5.1, it suffices to show that condition (5.10) implies (ii). Note from (5.14) and (5.15) that if \( d^2 \Psi(x_0|0)(w) \leq 0 \) then \( w \in \text{Ker } \Phi \cap \text{bd } C_f(x_0) \) and \( w \in E \). Since \( \text{Ker } \Phi \cap (E \cap \text{bd } C_f(x_0)) = \{0\} \) by (5.10), we have \( d^2 \Psi(x_0|0)(w) > 0 \) for all \( w \neq 0 \). It follows from Lemma 2.4 that \( x_0 \) is a strong solution. This verifies the equivalence between (i) and (ii).

To justify the equivalence between (i) and (iii), by (5.19), we only need to show that condition

\[
\text{Ker } \Phi \cap E \cap \text{bd } C_f(x_0) = \{0\}
\]

(5.21) in (5.10) is equivalent to the combination of \( \text{Ker } \Phi \cap E \cap \text{Ker } D_S^\ast = \{0\} \) and (5.18) provided that \( x_0 \) is a solution to (5.1). According to (5.20), (5.21) is equivalent to the condition that there exists some \( c > 0 \) such that

\[
k(w) \overset{\text{def}}{=} \langle De, w \rangle + \|D_S^\ast w\|_{\ell_1/\ell_2} \geq c\|w\| \quad \text{for all } w \in \text{Ker } \Phi \cap E.
\]

(5.22)

Since \( x_0 \) is a solution to (5.1), there exists \( v \in \mathbb{R}^p \) such that \( v \in \partial \|D^\ast x_0\|_{\ell_1/\ell_2} \) and \( Dv \in \text{Im } \Phi^\ast \). It follows that \( D(e + P_Sv) \in \text{Ker } M = \text{Im } \Phi^\ast + E^\perp \), we have \( MD_Sv = -MDe \). It follows from (2.2) that

\[
MD_S(MD_S)^\dagger MD_Te = MD_Te.
\]

For any \( w = M^\ast u \in \text{Ker } \Phi \cap C \) it follows that

\[
k(w) = k(M^\ast u) = \langle De, M^\ast u \rangle + \|D_S^\ast M^\ast u\|_{\ell_1/\ell_2}
\]

\[
= \langle MD_Te, u \rangle + \|D_S^\ast w\|_{\ell_1/\ell_2}
\]

\[
= \langle (MD_S)^\dagger MD_Te, D_S^\ast M^\ast u \rangle + \|D_S^\ast M^\ast u\|_{\ell_1/\ell_2}.
\]

(5.23)

Mimicking the proof of Theorem 4.6 by replacing \( N \) there by \( M \) and \( \text{Ker } \Phi \) by its subspace \( \text{Ker } \Phi \cap E \), the inequality \( k(w) \geq c\|w\| \) in (5.22) is equivalent to (iii). The proof is complete.

It is worth noting that condition

\[
\text{Ker } \Phi \cap E \cap \text{Ker } D_S^\ast = \{0\}
\]

(5.24)

in part (iii) is strictly weaker than the Restricted Injectivity in Theorem 4.6; see Example 3.9. It means that \( \Phi \) is injective on the subspace \( E \cap \text{Ker } D_S^\ast \). We refer (5.24) as Strong Restricted Injectivity condition. Moreover, we call the constant \( \zeta(e) \) Strong Source Coefficient, while the condition \( \zeta(e) < 1 \) is referred as Analysis Nondegenerate Source Condition for solution uniqueness to \( \ell_1/\ell_2 \) problem (1.2).

**Remark 5.4** (Checking the Strong Restricted Injectivity and the Analysis Nondegenerate Source Condition). Set the matrix \( S \overset{\text{def}}{=} ((D^\ast x_0)_{g})_{g \in I} \) to be an \( p \times |I| \) matrix, where \( |I| \) is the cardinality of \( I \). Observe from (5.15) that \( w \in E \) if and only if the following system

\[
D_T^\ast w = S\lambda \quad \text{is consistent with } \lambda \in \mathbb{R}^{|I|}.
\]

Since \( S \) is injective, we have \( \lambda = S^\dagger D_T^\ast w = (S^\ast S)^{-1}S^\ast D_T^\ast w \) due to (2.2). It follows that \( w \in E \) if and only if

\[
S(S^\ast S)^{-1}S^\ast D_T^\ast w - D_T^\ast w = 0
\]

(5.25)

Note that \( S^\ast S = \text{diag} \left( \|D^\ast x_0\|_g^2 \right)_{b \in I} \) is an \( |I| \times |I| \) diagonal matrix. Representing \( S \) in terms of groups, we have

\[
S(S^\ast S)^{-1}S^\ast = \text{diag} \left( \sum_{g \in I} \|D^\ast x_0\|_g^{-2} \delta_g \right) SS^\ast,
\]

34
where \( \delta_g = (0, \ldots, 0, 1, 1, \ldots, 1, 0, \ldots, 0) \) is the unit vector in \( V_g \). This together with (5.25) tells us that \( \mathcal{E} \) is the kernel of the following matrix

\[
Q = \text{diag} \left( \sum_{g \in I} \| (D_T^* x_0)_g \|_g^2 \delta_g \right) D_T^* - SS^* D_T^* \quad \text{with} \quad S = ((D_T^* x_0)_g)_{g \in I}.
\] (5.26)

The Strong Restricted Injectivity (5.24) is equivalent to \( \ker \left( \begin{pmatrix} \Phi \\ Q \end{pmatrix} \right) \cap \ker D^*_S = \{0\} \).

Furthermore, \( M^* \) forms a basis matrix of \( \ker \left( \begin{pmatrix} \Phi \\ Q \end{pmatrix} \right) \), which is found from the SVD of \( \begin{pmatrix} \Phi \\ Q \end{pmatrix} \). Similarly to (4.11), \( \zeta(e) \) is the optimal solution to

\[
\min \|z\|_{\ell_2/\ell_\infty} \quad \text{such that} \quad MDz = -MDe \quad \text{and} \quad z \in \bigoplus_{g \in I} V_g.
\] (5.27)

So \( \zeta^2(e) \) is the optimal value to the following convex optimization problem

\[
\min_{t \geq 0, z} \quad \text{such that} \quad MDz = -MDe, \quad \|z_g\|^2 - t \leq 0, \quad g \in I \quad \text{and} \quad z \in \bigoplus_{g \in I} V_g
\] (5.28)

with \(|I|G + 1\) variables, which can be solved by available packages such as \texttt{cvxopt}; see Section 6 for further discussion.

Next we show that \( \zeta(e) \leq \rho(e) \) when \( x_0 \) is an optimal solution to (5.1).

**Proposition 5.5** (Comparison between \( \rho(e) \) and \( \zeta(e) \)). Suppose that \( x_0 \) is an optimal solution to (5.1). Then we have \( \zeta(e) \leq \rho(e) \leq 1 \).

**Proof.** It follows from (4.6) that

\[
ND_S(ND_S)^\dagger ND_T = ND_T \quad \text{and} \quad \rho(e) \leq 1.
\]

For any \( w \in \ker \Phi \cap \mathcal{E} = \im M^* \subset \ker \Phi = \im N^* \), it is similar to (5.23) that

\[
\langle D_T e, w \rangle = \langle (ND_S)^\dagger ND_T e, D^*_S w \rangle = \langle (ND_S)^\dagger ND_T e, D^*_S w \rangle
\]

Note from the definition in (5.18) that

\[
\zeta(e) = \sup_{\|v\| \leq 1} \langle -(ND_S)^\dagger ND_T e, v \rangle - t \im D_S^{\dagger M^*} (v)
\]

\[
= \sup_{\|v\| \leq 1} \langle -(ND_S)^\dagger ND_T e, v \rangle - t \im D_S^{\dagger M^*} (v)
\]

\[
= \min_{u \in \ker MD_{ND_S}} \| (ND_S)^\dagger ND_T e - u \|_{\ell_\infty/\ell_2}. \tag{5.29}
\]

Since \( \ker ND_S \subset \ker MD_{ND_S} \), we have \( \zeta(e) \leq \rho(e) \). 

Although \( \zeta(e) \) could be computed by involving \( N \) via (5.29), the format in (5.18) is more preferable. This is due to the fact that the Moore-Penrose inverse \( MD_S^\dagger \) has a closed form as \( (MD_S)^* (MD_S (MD_S)^*)^{-1} \) when the Strong Restricted Injectivity (5.24) is in charged. In general, \( \rho(e) \) is strictly smaller \( \zeta(e) \). This fact is obtained through numerical experiments in our Section 6.

By replacing \( \zeta(e) \) by \( \rho(e) \) in Theorem 5.3, we do not need to assume \( x_0 \) to be an optimal solution, but we only have a sufficient condition for solution of uniqueness.
**Corollary 5.6** (Sufficient condition for solution uniqueness to $\ell_1/\ell_2$ problem). $x_0$ is the unique solution to problem (5.1) provided that $\rho(e) < 1$ and both conditions (4.6) and (5.24) are satisfied.

**Proof.** It follows directly from Proposition 4.4, Theorem 5.3, and Proposition 5.5. □

An simple upper bound for $\zeta(e)$ is

$$\zeta(e) \leq \gamma(e) \overset{\text{def}}{=} \| (MD_S)^{\dagger}MD_T e \|_{\ell_\infty/\ell_2},$$

which is also used in Section 6 to check solution uniqueness. The inequality is indeed strict. The following result is straightforward from Theorem 5.3.

**Corollary 5.7** (Sufficient condition for solution uniqueness to $\ell_1/\ell_2$ problem). Suppose that $x_0$ is an optimal solution to (5.1). Then the Strong Restricted Injectivity (5.24) at $x_0$ and $\gamma(e) < 1$ are sufficient for solution uniqueness at $x_0$. They become necessary conditions provided that $MD_S$ is injective.

In the spirit of Proposition 5.5, it is possible that $x_0$ is a unique solution to (5.1) but $\rho(e) = 1$. It means that the Nondegenerate Source Condition may not happen. However, the following result provides characterizations for solution uniqueness whose statement closely relates to the Nondegenerate Source Condition.

**Corollary 5.8** (Characterization for solution uniqueness to problem (5.1)). The following are equivalent:

(i) $x_0$ is the unique solution to problem (5.1).

(ii) With an arbitrary $v \in \mathbb{R}^p$ satisfying $Dv \in \text{Im} \Phi^*$, $P_T v = e$, and $\|P_S v\|_{\ell_\infty/\ell_2} \leq 1$, the following system has only trivial solution

$$\Phi w = 0, \quad w \in \mathcal{E}, \text{ and } D_S^* w \in \text{cone} \{v_g | g \in L\} \times \{0_H\},$$

where $L \overset{\text{def}}{=} \{g \in K | \|v_g\| = 1\}$ and $H \overset{\text{def}}{=} K \setminus L$.

**Proof.** Pick an arbitrary $v \in \mathbb{R}^p$ satisfying $Dv \in \text{Im} \Phi^*$, $P_T v = e$, and $\|P_S v\|_{\ell_\infty/\ell_2} \leq 1$. Such an $v$ always exists as when $x_0$ is a solution to (5.1), i.e., $\text{Ker} \Phi \cap \text{int} \mathcal{C}_f(x_0) = \emptyset$. We claim that

$$\text{Ker} \Phi \cap \text{bd} \mathcal{C}_f(x_0) = \{w \in \text{Ker} \Phi | D_S^* w \in \text{cone} \{v_g | g \in L\} \times \{0_H\}\}$$

(5.31)

with $L = \{g \in K | \|v_g\| = 1\}$ and $H = K \setminus L$. For any $w \in \text{Ker} \Phi$, note that

$$\langle D e, w \rangle + \|D_S^* w\| = \langle Dv, w \rangle - \langle DP_S v, w \rangle + \|D_S^* w\| = \langle P_S v, D_S^* w \rangle + \|D_S^* w\|_{\ell_1/\ell_2}$$

$$= \sum_{g \in L} (-\langle v_g, (D_S^* w)_g \rangle) + \|D(S^* T w)_g\| \geq \sum_{g \in H} \sum_{g \in H} \|D(S^* T w)_g\| \geq 0.$$  

It follows that $w \in \text{bd} \mathcal{C}_f(x_0)$ if and only if there exist $\lambda_g \geq 0, g \in L$ such that $(D_S^* w)_g = \lambda_g v_g$ for any $g \in L$ and $(D_S^* T w)_g = 0$ for any $g \in H$, which verifies (5.31). The equivalence between (i) and (ii) follows from Theorem 5.1. □

As $\text{Ker} \Phi \cap \mathcal{E} \cap \text{bd} \mathcal{C}_f(x_0) \subset \text{Ker} \Phi \cap \text{Ker} D_{V_H}^*$ with $V_H \overset{\text{def}}{=} \bigoplus_{g \in H} V_{g'}$, the following result is straightforward from Corollary 5.6.
Corollary 5.9 (Sufficient condition to the solution uniqueness to problem (5.1)). $x_0$ is the unique solution to problem (5.1) provided that there exists some $v$ such that $Dv \in \text{Im} \Phi^*$, $P_T v = e$, $\|P_S v\|_{\ell_0/\ell_2} \leq 1$, and that

$$\text{Ker} \Phi \cap \text{Ker} D_{V_H}^* = \{0\}$$

(5.32)

with $K = \{g \in J \mid \|v_g\| = 1\}$, $H = J \setminus K$, and $V_{\text{H}} \overset{\text{def}}{=} \bigoplus_{g \in H} V_g$.

The sufficient condition in [18, Proposition 7.1] is a special case of Corollary 5.9 where $D^*$ is the discrete gradient operator. Moreover, [21, Theorem 3.4] and [33, Theorem 3] even assume a stronger condition as they require $K = \emptyset$. Let us revisit Example 3.9. Pick any $v \in \partial\|x_0\|_{\ell_1/\ell_2} \cap \text{Im} \Phi^*$, i.e., $v \in (0, 1) \times [-1, 1] \cap \text{Im} \{ (1, 1, 0), (1, 0, -1) \}$. It follows that $v = (0, 1, 1)$ and thus $K = \{3\}$, $H = \emptyset$, which clearly implies (5.32).

According to Theorem 5.3, Theorem 3.12, and Proposition 3.1, solution uniqueness to group-sparsity problem (5.1) is equivalent to the robust recovery with rate $O(\sqrt{\delta})$.

Corollary 5.10 (Robust recovery and solution uniqueness for group-sparsity problems). The following statements are equivalent:

(i) $x_0$ is a unique solution to (5.1).

(ii) For sufficiently small $\delta > 0$, any solution $x_\delta$ to problem (1.4) with $J_0(\cdot) = \| \cdot \|_{\ell_1/\ell_2}$ satisfies $\|x_\delta - x_0\| \leq O(\sqrt{\delta})$ whenever $\|y - y_0\| \leq \delta$.

(iii) For any $c_1 > 0$ and sufficiently small $\delta > 0$, any solution $x_\mu$ to (1.5) with $J_0(\cdot) = \| \cdot \|_{\ell_1/\ell_2}$ satisfies $\|x_\mu - x_0\| \leq O(\sqrt{\delta})$ whenever $\|y - y_0\| \leq \delta$ and $\mu = c_1 \delta$.

From Theorem 5.3, it is natural to raise the following question for other decomposable norm minimization problem.

(Q.3) If $x_0$ is a unique solution to (1.2), can it be a strong solution to (1.2)?

The answer to (Q.3) is affirmative for $\ell_1/\ell_2$ problem as in Theorem 5.3. For the $\ell_1$ problem when $\| \cdot \|_A = \| \cdot \|_1$, we also have the positive answer due to Corollary 4.13. However, it is not the case for the nuclear norm minimization problem. The following example modifies [4, Example 3.1] to prove that claim.

Example 5.11 (Difference between unique solution and strong solution to NNM). Consider the following optimization problem

$$\min_{X \in \mathbb{R}^{2 \times 2}} \|X\|_* \quad \text{such that} \quad \Phi(X) \overset{\text{def}}{=} \left( \begin{array}{cc} x_{11} + x_{22} \\ x_{12} - x_{21} + x_{22} \end{array} \right) = \left( \begin{array}{c} 1 \\ 0 \end{array} \right).$$

(5.33)

For any $X = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right)$ with $a + d = 1$ and $b - c + d = 0$, we obtain from (4.37) that

$$\|X\|_* = \sqrt{a^2 + b^2 + c^2 + d^2 + 2|ad - bc|} \geq \sqrt{|a + d|^2 + |b - c|^2} \geq 1,$$

where the equality occurs when $\|X\|_* = 1$, $b - c = 0$, $a + d = 1$, and $b - c + d = 0$, which means $b = c$, $a = 1$, $d = 0$, and $\|X\|_* = \sqrt{1 + b^2 + c^2 + 2|bc|} = 1$. So $X = \left( \begin{array}{cc} 1 & 0 \\ 0 & 0 \end{array} \right)$ is the unique solution to
problem (5.33). Choose \( X_\varepsilon = \begin{pmatrix} 1 - \varepsilon^{1.5} & \varepsilon - \varepsilon^{1.5} \\ \varepsilon - \varepsilon^{1.5} & \varepsilon^{1.5} \end{pmatrix} \) with \( \varepsilon > 0 \) sufficiently small and note that \( X_\varepsilon \) satisfies the equation in (5.33). It follows that

\[
\|X_\varepsilon\|_* - \|X\|_* = \sqrt{(1 - \varepsilon^{1.5})^2 + (\varepsilon - \varepsilon^{1.5})^2 + \varepsilon^2 + \varepsilon^3 + 2(1 - \varepsilon^{1.5})\varepsilon^{1.5} - (\varepsilon - \varepsilon^{1.5})\varepsilon} - 1
\]

Moreover,
\[
\|X_\varepsilon - X\|_*^2 = \varepsilon^3 + (\varepsilon - \varepsilon^{1.5})^2 + \varepsilon^2 + \varepsilon^3 = O(\varepsilon^2).
\]

This tells us that \( X \) is not a strong solution to (5.33).

5.3 Connections between unique/strong solutions in the noiseless case

Let us consider the particular case of problem (4.27), which reads

\[
\min \Theta(x) \overset{\text{def}}{=} f(\Phi x) + \mu \|D^* x\|_{\ell_1/\ell_2} \tag{5.34}
\]

with constant \( \mu > 0 \). In the following result, we show that a unique solution to (5.34) is also a strong solution. Consequently, all the characterizations for solution uniqueness to (5.1) in this section can be used to characterize unique/strong solutions to problem (5.34) due to Proposition 4.12. Moreover, this result gives an affirmative answer for (Q.2) in the previous section.

**Theorem 5.12** (Characterization to solution uniqueness to \( \ell_1/\ell_2 \) regularized problem). Suppose that \( \bar{x} \) is an optimal solution to problem (5.34). The following are equivalent:

(i) \( \bar{x} \) is the unique solution to (5.34).

(ii) \( \bar{x} \) is the strong solution to (5.34).

(iii) \( \bar{x} \) is the strong solution to (5.1) with \( x_0 = \bar{x} \).

**Proof.** (i) and (iii) are equivalent due to Proposition 4.12 and Theorem 5.3. [(ii)⇒(i)] is trivial. It suffices to verify [(iii)⇒(ii)]. Suppose that \( \bar{x} \) is a strong solution to (5.1). By Theorem 5.3 and Theorem 5.1, \( \ker \Phi \cap E \cap \partial C_I(x_0) = \{0\} \). Since \( \bar{x} \) is an optimal solution to (5.12), we have

\[
0 \in \partial \Theta(\bar{x}) = \Phi^* \nabla f(\Phi \bar{x}) + D\partial\|D^* \bar{x}\|_{\ell_1/\ell_2} \subset D\partial\|D^* \bar{x}\|_{\ell_1/\ell_2} + \operatorname{Im} \Phi^*.
\]

Thus there exists \( z \in D\|D^* \bar{x}\|_{\ell_1/\ell_2} \) such that

\[
D^* z = -\Phi^* \nabla f(\Phi \bar{x}), \quad P_T z = e, \quad \|P_S z\|_{\ell_{\infty}/\ell_2} \leq 1,
\]

where \( e, T, \) and \( I \) are defined at the beginning at the section with \( x_0 = \bar{x} \).

For any \( w \in \mathbb{R}^n \), note further that

\[
d^2 \Theta(\bar{x}; 0)(w) = \langle \Phi w, \nabla^2 f(\Phi \bar{x}) \Phi w \rangle + d^2 J(\bar{x}) Dz(\bar{x})(w) \tag{5.35}
\]

with \( J(x) = \|D^* x\|_{\ell_1/\ell_2} \). Since \( D_S^* \bar{x} = 0 \), we have

\[
d^2 J(\bar{x}) Dz(\bar{x})(w) = \liminf_{t \downarrow 0, w' \to w} \frac{\|D^* (x + tw')\|_{\ell_1/\ell_2} - \|D^* \bar{x}\|_{\ell_1/\ell_2}(\bar{x}) - t(Dz, w')}{t^2}
\]

\[
= \liminf_{t \downarrow 0, w' \to w} \left( \frac{\|D_T^*(x_0 + tw')\|_{\ell_1/\ell_2} - \|D_T^* x_0\|_{\ell_1/\ell_2}(\bar{x}) - t(De, w')}{t^2} + \frac{-\langle D_S^* z, w' \rangle + \|D_S^* w'\|_{\ell_1/\ell_2}}{t} \right).
\]
Note further that

\[-\langle D_S z, w' \rangle + \|D_S z\|_{\ell_1/\ell_2} = -\langle P_S z, D_S z' \rangle + \|D_S z\|_{\ell_1/\ell_2} \geq 0\]

as \(\|P_S z\|_{\ell_0/\ell_2} \leq 1\). It is similar to (5.16) and (5.17) that

\[
\text{dom} \ d^2 f(x \mid Dz) = \{w \in \mathbb{R}^n \mid -\langle DP_S z, w \rangle + \|D_S z\|_{\ell_1/\ell_2} = 0\} \overset{\text{def}}{=} \mathcal{F}, \tag{5.36}
\]

\[
d^2 J(\bar{x} \mid D\bar{z})(w) = \sum_{g \in I} \frac{\|((D_T^\top z)_g\|_2^2}{\|((D_T^\top x_0)_g\|_2^2} - \frac{\langle (D_T^\top w)_g, (D_T^\top x_0)_g \rangle^2}{\|((D_T^\top x_0)_g\|_2^3}. \tag{5.37}
\]

Since \(\nabla^2 f(\Phi \bar{x}) > 0\), we derive from (5.35), (5.36), and (5.37) that

\[
\text{Ker} \ d^2 \Theta(x \mid 0) = \text{Ker} \Phi \cap \mathcal{E} \cap \mathcal{F}.
\]

Furthermore, with \(w \in \text{Ker} \Phi\) we have \(\Phi w = 0\) and

\[
\langle DP_S z, w \rangle = \langle Dz, w \rangle - \langle De, w \rangle = \langle -\Phi^* \nabla f(\Phi \bar{x}), w \rangle - \langle De, w \rangle = -\langle De, w \rangle.
\]

This together with (5.36) implies that

\[
\text{Ker} \ d^2 \Theta(x \mid 0) = \text{Ker} \Phi \cap \mathcal{E} \cap \mathcal{F} = \text{Ker} \Phi \cap \mathcal{E} \cap \text{bd} C_f(x_0) = \{0\}.
\]

By Lemma 2.4, \(\bar{x}\) is a strong solution to problem (5.34). The proof is complete. \(\square\)

### 6 Numerical verification of solution uniqueness for group-sparsity

With an aim of demonstrating that our conditions for sharp, strong/unique solution are verifiable, we have implemented a simulation using synthetic data. In our simulation study, \(\Phi\) was generated as an \((2000 \times 240)\) Gaussian matrix whose entries are independently and identically drawn from the standard normal distribution, \(\mathcal{N}(0, 1)\). We next randomly divided the set of indicators range from 1 to 2000 into \(k = 100\) groups of size 20 with 5 randomly selected active groups. Then, we constructed a measured signal of length \(m = 240\), \(y_0 \overset{\text{def}}{=} \Phi x_0\), based on the original signal \(x_0\) whose elements in each active group are independently and identically distributed \(\mathcal{N}(0, 1)\). We then used our proposed conditions to verify whether \(x_0\) is a solution to (1.2) using the conditions in Proposition 4.4 and summarize the number of cases where \(x_0\) is classified as sharp or unique/strong solution by the criteria from Theorem 4.6 and 5.3. For checking strong and sharp minima, we only need to compute the Source Coefficient \(\rho(e)\) and the Strong Source Coefficient \(\zeta(e)\) whenever \(\tau(e)\) in (4.21) or \(\gamma(e)\) in (5.30) is greater than or equal to 1, respectively, since calculating these numbers are much easier. Similar to the scheme for calculating \(\zeta(e)\) in (5.28), \(\rho^2(e)\) is the optimal value to the following convex optimization problem (recall (4.11))

\[
\min_{t \geq 0, z} \text{ such that } NDz = -NDe, \quad \|z_g\|_2^2 \leq t, g \in K, \text{ and } z \in \bigoplus_{g \in K} V_g. \tag{6.1}
\]

where \(K\) is the set of inactive groups. Note that (5.28) and (6.1) are second-order cone programming problems and can be solved via function solvers.socp of cvxopt package. In our experiment, \(\rho(e)\) or \(\zeta(e)\) are calculated when \(\tau(e)\) or \(\gamma(e)\) is greater than or equal to 0.99.

The results are recorded in the following tree diagram.
In all 100 tested random cases, $x_0$ is verified as a solution to (1.2) and satisfying the Restricted Injectivity Condition. Among them, there are 11 cases with $\tau(e) < 0.99$ thus are classified as sharp solution, the rest are passed to next step for calculating $\rho(e)$. There are 60 cases with $\rho < 0.95$ and 29 tests with $0.95 < \rho(e) < 1.05$. Hence, we had 71 cases $x_0$ is the sharp solution. We continue the experiment by checking the strong solution condition on the rest 29 cases. Note that since all cases satisfy the Restricted Injectivity Condition, they automatically satisfy the Strong Restricted Injectivity Condition and it is left to check the Analysis Nondegenerate Source Condition. All 29 cases are indicated as satisfying the Analysis Nondegenerate Source Condition with 26 cases having $\gamma(e) < 0.99$ and 3 cases where $\gamma(e) \geq 0.99$ and $\zeta(e) < 0.95$. It means that we have 29 cases of strong solutions that are not sharp.

| number of cases          |
|--------------------------|
| Sharp solution           | 71           |
| Strong solution (non-sharp) | 29           |

Table 1: Number of cases with strong and sharp solutions

7 Conclusion

In this paper we show that sharp minima and strong minima play important roles for robust recovery with different rates. We also provide some quantitative characterizations for sharp solutions to convex regularized problems. Unique solutions to $\ell_1$ problems are actually sharp solutions. For group sparsity problems, unique solutions are strong solutions. We also obtain several conditions guaranteeing solution uniqueness to group sparsity problems. As solution uniqueness to $\ell_1$ problem plays a central role in the area of exact recovery with high probability, we plan to use our results to find a better bound for exact recovery for group-sparsity problems in comparison with the one obtained in [7, 29], at which they only use sufficient conditions for solution uniqueness.

Example 4.14 and Example 5.11 raise important questions about the solution uniqueness and strong minima for the nuclear norm minimization problems. Unique solutions to (1.2) with the
nuclear norm are neither sharp nor strong solutions. But a strong solution in this case is certainly a unique solution. It means that second-order analysis can provide a sufficient condition for solution uniqueness, and such a condition should be weaker than the one in Theorem 4.6 for sharp solutions. However, unlike the analysis in Lemma 5.2, the second subderivative of the nuclear norm is far more intricate to compute. Understanding solution uniqueness and strong minima for the case of the nuclear norm, or more generally for spectral functions, is a project that we plan to pursue in the future.
