We present results on the nucleon axial form factors within lattice QCD using two flavors of degenerate twisted mass fermions. Volume effects are examined using simulations at two volumes of spatial length \( L = 2.1 \text{ fm} \) and \( L = 2.8 \text{ fm} \). Cut-off effects are investigated using three different values of the lattice spacings, namely \( a = 0.089 \text{ fm} \), \( a = 0.070 \text{ fm} \) and \( a = 0.056 \text{ fm} \). The nucleon axial charge is obtained in the continuum limit and chirally extrapolated to the physical pion mass enabling comparison with experiment.

I. INTRODUCTION

The nucleon (N) form factors are fundamental hadronic observables that probe the structure of the nucleon. Experiments to measure the electromagnetic nucleon form factors have been carried out since the 50’s. A new generation of experiments using polarized beams and targets are currently under way at major facilities in order to measure the nucleon form factors more accurately and at higher values of the momentum transfer. The nucleon form factors connected to the axial vector current are more difficult to measure and therefore less accurately known than its electromagnetic form factors. As in the electromagnetic case the nucleon matrix element of the axial vector current is written in terms of two Lorentz invariant form factors, the axial form factor \( G_A(q^2) \) and the induced pseudo-scalar form factor, \( G_P(q^2) \) where \( q^2 \) is the momentum transfer squared. The nucleon charge \( g_A = G_A(0) \) which can be determined from \( \beta \)-decay, is known to high precision. The \( q^2 \)-dependence of \( G_A(q^2) \) has been studied from neutron scattering [1] and pion electroproduction [2,3] processes. The nucleon induced pseudo-scalar form factor, \( G_P(q^2) \), is even less well known. Muon capture at low \( q^2 \) values [4] and pion electroproduction for larger \( Q^2 \) [2,3] are the main experimental sources of information for \( G_P(Q^2) \). Both \( G_A(q^2) \) and \( G_P(q^2) \) have been discussed within chiral effective theories [5,6]. In this work we present results on these form factors obtained in lattice QCD using two degenerate light quarks (\( N_F=2 \)) in the twisted mass formulation [7].

Twisted mass fermions [8] provide an attractive formulation of lattice QCD that allows for automatic \( O(a) \) improvement, infrared regularization of small eigenvalues and fast dynamical simulations. For the calculation of the nucleon form factors in which we are interested in this work, the automatic \( O(a) \) improvement is particularly relevant since it is achieved by tuning only one parameter in the action, requiring no further improvements on the operator level.

The action for two degenerate flavors of quarks in twisted mass QCD is given by

\[
S = S_g + a^4 \sum_x \bar{\chi}(x) \left[ D_W + m_{\text{crit}} + i\gamma_5 \tau^3 \mu \right] \chi(x),
\]

where \( D_W \) is the Wilson Dirac operator and we use the tree-level Symanzik improved gauge action \( S_g \) [1]. The quark fields \( \chi \) are in the so-called “twisted basis” obtained from the “physical basis” at maximal twist by a simple transformation:

\[
\psi = \frac{1}{\sqrt{2}} \left[ 1 + i\tau^3 \gamma_5 \right] \chi \quad \text{and} \quad \bar{\psi} = \frac{1}{\sqrt{2}} \left[ 1 + i\tau^3 \gamma_5 \right] \bar{\chi}.
\]

We note that, in the continuum, this action is equivalent to the standard QCD action. A crucial advantage is the fact that by tuning a single parameter, namely the bare untwisted quark mass to its critical value \( m_{\text{crit}} \), a wide class of physical observables are automatically \( O(a) \) improved [7]. A disadvantage is the explicit flavor symmetry breaking. In a recent paper we have checked that this
breaking is small for the baryon observables under consideration in this work and for the lattice spacings that we use [10–14]. To extract the nucleon FFs we need to evaluate the nucleon matrix elements \( \langle N(p',s')|A^a_\mu|N(p,s) \rangle \), where \( |N(p',s')\rangle \), \( |N(p,s)\rangle \) are nucleon states with final (initial) momentum \( p'(p) \) and spin \( s'(s) \). Due to its isovector nature, the axial vector current, defined by

\[
A^a_\mu(x) = \bar{\psi}(x)\gamma_\mu\gamma_5\gamma^a\frac{1}{2}\psi(x),
\]

receives contributions only from the connected diagram for \( a = 1, 2 \) and up to \( O(a) \) for \( a = 3 \). Simulations including a dynamical strange quark are also available within the twisted mass formulation. Comparison of the nucleon mass obtained with two dynamical flavors and the nucleon mass including a dynamical strange quark has shown negligible dependence on the dynamical strange quark mass including a dynamical strange quark has shown negligible dependence on the dynamical strange quark mass [13]. We therefore expect the results on the nucleon form factors to show little sensitivity on a dynamical strange quark as well.

The axial current matrix element of the nucleon \( \langle N(p',s')|A^a_\mu|N(p,s) \rangle \) can be expressed in terms of the form factors \( G_A \) and \( G_p \) as

\[
\langle N(p',s')|A^a_\mu|N(p,s) \rangle = i \left( \frac{m_N^2}{E_N(p')E_N(p)} \right)^{1/2} a_{N}(p',s')\left[ G_A(q^2\gamma^a\gamma_5 + \frac{q^2\gamma_5}{2m_N} G_\mu(q^2) \right] \frac{1}{2} u_N(p,s).
\]

In this work we consider simulations at three values of the coupling constant spanning lattice spacings from about 0.05 fm to 0.09 fm. This enables us to obtain results in the continuum limit. We find that cut-off effects are small for this range of lattice spacings. We also examine finite size effects on the axial form factors by comparing results on two lattices of spatial length \( L = 2.1 \) fm and \( L = 2.8 \) fm [16–18].

**II. LATTICE EVALUATION**

**A. Correlation functions**

The nucleon interpolating field in the physical basis is given by

\[
J(x) = e^{abc} [u^\dagger(x)C\gamma_5d^b(x)] u^c(x)
\]

and can be written in the twisted basis at maximal twist as

\[
\tilde{J}(x) = \frac{1}{\sqrt{2}} [1 + i\gamma_5] e^{abc} [\tilde{u}^\dagger(x)C\gamma_5\tilde{d}^b(x)] \tilde{u}^c(x).
\]

The transformation of the axial vector current, \( A^a_\mu(x) \), to the twisted basis leaves the form of \( A^a_\mu(x) \) unchanged. The axial renormalization constant \( Z_A \) is determined non-perturbatively in the RI-MOM scheme using two approaches [19, 20] and [21, 22] both of which yield consistent values. We use the values of \( Z_A \) found in latter approach [21], which employs a momentum source [23] and a perturbative subtraction of \( O(a^2) \) terms [24, 25]. This subtracts the leading cut-off effects yielding only a very weak dependence of \( Z_A \) on \( (ap)^2 \) for which the \( (ap)^2 \rightarrow 0 \) limit can be reliably taken. It was also shown with high accuracy that the quark mass dependence of \( Z_A \) is negligible. We find the values

\[
Z_A = 0.757(3), \quad 0.776(3), \quad 0.789(3)
\]

at \( \beta = 3.9, 4.05 \) and 4.2 respectively. These are the values of \( Z_A \) which we use in this work to renormalize the lattice matrix element.

In order to increase the overlap with the proton state and decrease overlap with excited states we use Gaussian smeared quark fields [24, 25] for the construction of the interpolating fields:

\[
q_{\text{smear}}(t, \vec{x}) = \sum_{\vec{y}} F^{ab}(\vec{x}, \vec{y}; U(t)) q^b(t, \vec{y}),
\]

\[
F = (1 + \alpha H)^n,
\]

\[
H(\vec{x}, \vec{y}; U(t)) = \sum_{i=1}^3 [U_i(x)\delta_{x,y-i} + U_i^\dagger(x-i)\delta_{x,y+i}].
\]

In addition, we apply APE-smearing to the gauge fields \( U_\mu \) entering the hopping matrix \( H \). The smearing parameters are the same as those used for our calculation of baryon masses with \( \alpha \) and \( n \) optimized for the nucleon ground state [13]. The values are: \( \alpha = 4.0 \) and \( n = 50 \), 70 and 90 for \( \beta = 3.9, 4.05 \) and 4.2 respectively.

In order to calculate the nucleon matrix element of Eq. 4 we calculate the two-point and three-point functions defined by

\[
G(q, \vec{t}, \vec{x}_f) = \sum_{\vec{x}_f} e^{-i\vec{x}_f \cdot \vec{q}} \Gamma_0^{\beta_\alpha} (J_\alpha(t_f, \vec{x}_f)J_{\beta}(t_i, \vec{x}_i))
\]

\[
G^{\mu}(\vec{x}_f, \vec{t}, \vec{x}, \vec{t}_f) = \sum_{\vec{x}_f} e^{+i\vec{x}_f \cdot \vec{q}} \Gamma^{\mu}_{\beta_\alpha} (J_\alpha(t_f, \vec{x}_f)A^\mu(t, \vec{x})J_{\beta}(t_i, \vec{x}_i)),
\]

where \( \Gamma^0 \) and \( \Gamma^k \) are the projection matrices:

\[
\Gamma^0 = \frac{1}{4}(1 + \gamma_0), \quad \Gamma^k = i\Gamma^0\gamma_5\gamma_k.
\]
Q

ties are given in Euclidean space and where

current couples to a quark at an intermediate time

\( \vec{q} \)

ing sequential inversions through the sink yielding the

the plateau range. As mentioned already, only the con-

tribution factors cancel for the ratio

\[ \Pi^\mu(\Gamma, \vec{q}, t) = \frac{E^\mu(\Gamma, \vec{q}, t)}{G(\vec{p}, t)} \frac{G(\vec{p}, t) - G(\vec{p}, t)}{G(\vec{p}, t) - G(\vec{p}, t)} \]

yielding a time-independent value

\[ R^\mu(\Gamma, \vec{q}, t) = \Pi^\mu(\Gamma, \vec{q}) \] (11)

We refer to the range of \( t \)-values where this asymptotic behavior is observed within our statistical precision as the plateau range. As mentioned already, only the con-

ected diagram contributes. It is calculated by perform-

ing sequential inversions through the sink yielding the

form factors at all possible momentum transfers and cur-

current orientation \( \mu \). Since we use sequential inversions

through the sink we need to fix the sink-source separation. Statistical errors increase rapidly as we increase

the sink-source separation. Therefore we need to choose

the smallest possible that still ensures that the nucleon ground state dominates when measurements are made at different values of \( t \). In order to check that a sink-source time separation of \( \sim 1 \) fm is sufficient for the isolation

of the nucleon ground state we compare the results at \( \beta=3.9 \) obtained with \( t_f/a=12 \) i.e. \( t_f \sim 1 \) fm with those

obtained when we increase to \( t_f/a=14 \). As can be

seen in Fig. 2 where we plot \( R^\mu(\Gamma, \vec{q}, t) \), the plateau val-

ues are compatible yielding the same plateau value for

the two time separations. This means that the shorter

sink-source separation is sufficient and the ground state

of the nucleon dominates in the plateau region. We there-

fore use in all of our analysis \( t_f - t_i \sim 1 \) fm.

New inversions are necessary every time a different choice of the projection matrix \( \Gamma^\alpha \) is made. In this work, we consider choices, which are optimal for the form factors considered. Namely we use the spatial \( \Gamma^\alpha \)'s and con-

sider the spatial component of the current i.e. we extract the

form factors from

\[ \Pi^\mu(\Gamma^k, \vec{q}) = \frac{i c}{4m} \left[ \frac{q_k q_i}{2m} G(p(Q^2) - (E + m) \delta_{i,k} G_A(Q^2) \right] \]

where \( k = 1, 2, 3 \), and \( c = \sqrt{\frac{2m^2}{m^2 - m_\pi^2}} \).

B. Simulation details

The input parameters of the calculation, namely \( \beta, L/a \) and \( a \mu \) are summarized in Table I. The lattice spac-

ing \( a \) is taken from the nucleon mass as described in the

next section. The pion mass values, spanning a mass

range from 260 to 470 MeV, are taken from Ref. [28]. At

\( m_\pi \approx 300 \) MeV and \( \beta=3.9 \) we have simulations for lat-

tices of spatial size \( L=2.1 \) fm and \( L=2.8 \) fm allowing to

investigate finite size effects. Finite lattice spacing effects

are studied using three sets of results at \( \beta=3.9, \beta=4.05 \)

and \( \beta=4.2 \) for the lowest and largest pion mass avail-

able in this work. These sets of gauge ensembles allow us

to estimate all the systematic errors in order to produce

reliable predictions for the nucleon axial form factors.

C. Determination of the lattice spacing

The nucleon mass has been computed on the same en-

sembles that are now used here for the computation of the

nucleon axial form factors [13]. Therefore we can use the

nucleon mass at the physical point to set the scale. We show in Fig. 3 results at three values of the lattice spac-
\[ m_N = m_0^N - 4c_1 m_\pi^2 - \frac{3g_A^2}{16\sqrt{2}} m_\pi^3. \]  

We perform a fit to the volume corrected results at \( \beta=3.9 \), \( \beta=4.05 \) and \( \beta=4.2 \) and extract \( r_0=0.462(5) \) fm. Fittings corresponding to \( \beta=3.9 \), \( \beta=4.05 \) and \( \beta=4.2 \). As can be seen, cut-off effects are negligible and we can therefore use continuum chiral perturbation theory to extrapolate to the physical point. For the observables discussed in this work the nucleon mass at the physical point is the most appropriate quantity to set the scale. This also provides a cross-check for the determination of the lattice spacing as compared to the pion decay constant used in the meson sector. If lattice artifacts are under control then these two determinations should be consistent, under the assumption that quenching effects due to the absence of the strange quark from the sea are small for these quantities. In order to correct for volume effects we use chiral perturbation theory to take into account volume corrections coming from pions propagating around the lattice, following Ref. [29]. A similar analysis was carried out in Ref. [11] at \( \beta=3.9 \) and \( \beta=4.05 \) and we refer to this publication for additional details. In addition, this work is extended by an analysis of results at \( \beta=4.2 \). In Table I we give the volume corrected nucleon mass.

To chirally extrapolate we use the well-established \( O(p^3) \) result of heavy baryon chiral perturbation theory (HB\( \chi \)PT) given by

\[
am_N(L \rightarrow \infty) = am_N + L m_N \chi_{\text{PT}} + O(p^5).
\]

We perform a fit to the data at \( \beta=3.9 \), \( \beta=4.05 \) and \( \beta=4.2 \) and extract \( r_0=0.462(5) \) fm. Fitting instead to the \( \beta=3.9 \) and \( \beta=4.05 \) results we find \( r_0=0.465(6) \) fm showing that indeed cut-off effects are small. To estimate the error due to the chiral extrapolation we use HB\( \chi \)PT to \( O(p^3) \), which leads to \( r_0=0.489(11) \). We take the difference between the \( O(p^3) \)

| \( \beta \) | \( a \) | \( r_0/a \) |
|---|---|---|
| 3.9 | 0.089(1) | 5.22(2) |
| 4.05 | 0.070(1) | 6.61(3) |
| 4.2 | 0.056(1) | 8.31 |

**TABLE I:** Input parameters \( (\beta, L, a\mu) \) of our lattice calculation and corresponding lattice spacing \( a \) and pion mass \( m_\pi \).

| \( \beta \) | \( am_\pi \) | \( Lm_\pi \) | \( am_N \) | \( am_N(L \rightarrow \infty) \) |
|---|---|---|---|---|
| 3.9 | 0.2100(5) | 5.04 | 0.5973(43) | 0.5952 |
| 4.05 | 0.1940(5) | 4.66 | 0.5786(67) | 0.5760 |
| 4.2 | 0.1684(2) | 4.06 | 0.5514(49) | 0.5468 |

**TABLE II:** Results on the nucleon mass. The last column gives the values after a volume correction.
FIG. 3: Nucleon mass in units of $r_0$ at three lattice spacings and spatial lattice size $L$ such that $m_\pi L > 3.3$. The solid (black) and dashed (red) lines are fits to $O(p^3)$ and $O(p^4)$ HB$\chi$PT. The physical point is shown with the asterisks. Results at $\beta = 3.9$ and $24^3 \times 48$ are shown with filled (red) circles, at $\beta = 3.9$ and $32^3 \times 64$ with the filled (blue) squares, at $\beta = 4.05$ and $32^3 \times 64$ with the filled (green) triangles, at $\beta = 4.2$ and $32^3 \times 64$ with the open (yellow) square and at $\beta = 4.2$ and $48^3 \times 96$ with the star (magenta). and $O(p^4)$ mean values as an estimate of the uncertainty due to the chiral extrapolation. Fits to other higher order $\chi$PT formulae are also shown in Fig. 3. These are described in Ref. [13] and are consistent with $O(p^4)$ HB$\chi$PT. Using $r_0 = 0.462(5)(27)$ and the computed $r_0/a$ ratios we obtain

\begin{align*}
  a_{\beta=3.9} &= 0.089(1)(5), \\
  a_{\beta=4.05} &= 0.070(1)(4), \\
  a_{\beta=4.2} &= 0.056(2)(3).
\end{align*}

These values are consistent with the lattice spacings determined from $f_\pi$ and will be used for converting to physical units in what follows. We note that results on the nucleon mass using twisted mass fermions agree with those obtained using other lattice $O(a^2)$ formulations for lattice spacings below 0.1 fm [11].

III. RESULTS

In the first subsection we discuss our results on the nucleon axial charge and in the second subsection we discuss the momentum dependence of the axial $G_A(Q^2)$ and the induced pseudo-scalar $G_P(Q^2)$.

A. Axial charge

Our lattice results on the nucleon axial charge are shown in Fig. 4 and listed in Table III. In the same figure we also show results obtained using $N_F = 2 + 1$ domain wall fermions (DWF) by the RBC-UKQCD collaborations [30] and using a mixed action with 2+1 flavors of asqtad sea and domain wall valence fermions by LHPC [31]. The first observation is that results at our three different lattice spacings are within error bars. The second observation is that results at two different volumes are also consistent. The third observation is that there is agreement among lattice results using different lattice actions even before taking the continuum and infinite volume limit.

| $m_\pi$ | $Lm_\pi$ | $g_A$ | $g_A(L \to \infty)$ |
|---------|----------|-------|---------------------|
| $\beta = 3.9$ |
| 0.4675  | 5.04     | 1.163(18) | 1.167 |
| 0.4319  | 4.66     | 1.134(25) | 1.140 |
| 0.3770  | 4.06     | 1.140(27) | 1.150 |
| 0.3032  | 3.27     | 1.111(34) | 1.133 |
| 0.2978  | 4.28     | 1.103(32) | 1.106 |
| 0.2600  | 3.74     | 1.156(47) | 1.162 |
| $\beta = 4.05$ |
| 0.4653  | 5.28     | 1.173(24) | 1.177 |
| 0.4035  | 4.58     | 1.175(31) | 1.182 |
| 0.2925  | 3.32     | 1.194(66) | 1.218 |
| $\beta = 4.2$ |
| 0.4698  | 4.24     | 1.130(26) | 1.144 |
| 0.2622  | 3.55     | 1.138(43) | 1.146 |

TABLE III: Results using $N_F = 2$ twisted mass fermions (TMF) on the axial nucleon charge. The last column gives the values after a volume correction.
In order to assess volume effects we plot in Fig. 5 results on $g_A$ versus $L m_\pi$. Besides TMF results we show the results obtained using $N_F = 2+1$ DWF \cite{30} as well as within the mixed action approach \cite{31}. As can be seen the results are consistent with a constant in the whole range of $L m_\pi$ spanned. In particular we do not observe a decrease in the value of $g_A$ for values of $L m_\pi \sim 3.3$. Therefore, given that finite volume effects are negligible for the smallest value of $m_\pi L = 3.3$ as compared to the value we find at $m_\pi L = 4.3$, we conclude that for all of our data for which $m_\pi L > 3.3$ volume effects are small.

We can estimate the volume correction on $g_A$ within heavy baryon chiral perturbation theory (HB$\chi$PT) in the so called small scale expansion (SSE) \cite{32}, which includes explicitly the $\Delta$ degree of freedom. In this scheme one expands the results in powers of a small parameter $\epsilon$, which denotes small pion four-momenta, the pion mass, baryon three-momenta and the nucleon-$\Delta$ mass splitting in the chiral limit. Writing

$$g_A(m_\pi, \infty) = g_A(m_\pi, L) - \Delta g_A(m_\pi, L)$$

the dependence of $g_A$ on the spatial length $L$ of the lattice is given by \cite{32}

$$\Delta g_A(m_\pi, L) = \frac{g_A^0 m_\pi^2}{4 \pi^2 f_\pi^2} \sum_{\vec{n}} \frac{K_1(L|\vec{n}|m_\pi)}{L|\vec{n}|m_\pi}$$

$$+ \frac{(g_A^0)^3 m_\pi^2}{6 \pi^2 f_\pi^2} \sum_{\vec{n}} \left[ K_0(L|\vec{n}|m_\pi) - \frac{K_1(L|\vec{n}|m_\pi)}{L|\vec{n}|m_\pi} \right]$$

$$+ \frac{c_A^2}{\pi f_\pi^2} \left( \frac{25}{81} g_1 - g_A^0 \right) \int_0^\infty dy \sum_{\vec{n}} \frac{f(m_\pi, y)}{L|\vec{n}|m_\pi} K_0(L|\vec{n}|f(m_\pi, y))$$

$$- \frac{L|\vec{n}|f(m_\pi, y)}{3} K_1(L|\vec{n}|f(m_\pi, y))$$

$$+ \frac{8 c_A^2 g_A^0}{27 \pi f_\pi^2} \int_0^\infty dy \sum_{\vec{n}} \frac{f(m_\pi, y)}{\Delta_0} \left[ K_0(L|\vec{n}|f(m_\pi, y)) - \frac{K_1(L|\vec{n}|f(m_\pi, y))}{L|\vec{n}|f(m_\pi, y)} \right]$$

$$+ \frac{4 c_A^2 g_A^0 m_\pi^3}{27 \pi f_\pi^2} \sum_{\vec{n}} \frac{1}{L|\vec{n}|m_\pi} e^{-L|\vec{n}|m_\pi} + O(\epsilon^4)$$

\textbf{FIG. 6:} The nucleon axial charge as a function of the lattice spacing in units of $r_0$ at: $r_0 m_\pi = 0.615$, $r_0 m_\pi = 0.85$, $r_0 m_\pi = 0.95$, $r_0 m_\pi = 1.10$, from top to bottom. We use $r_0 = 0.462(5)$ extracted from the nucleon mass. In the upper most and lower most graphs we show both the linear (dotted line) and constant fits (dashed line).
with \( f(m, y) = \sqrt{m^2 + y^2} + 2y\Delta_0 \) and \( f_\pi \) the pion decay constant in the chiral limit which we approximate with its physical value i.e. we take \( f_\pi = 0.092 \text{ GeV} \). In the sum \( \sum^\prime \), all vectors \( \vec{n} \) are summed except \( \vec{n} = 0 \). In order to estimate the volume correction \( \Delta g_A \) we take the experimental value of the axial charge in the chiral limit i.e. \( g_A^0 \sim g_A^{\text{exp}} \sim 1.267 \) and the nucleon - \( \Delta \) mass splitting in the chiral limit \( \Delta_0 = 0.2711 \). For the \( \Delta \) axial coupling constant we use the SU(4) relation
\[
\frac{c_\gamma}{\Lambda} = c_A \frac{c_\gamma}{\Lambda} \frac{g_A}{\Lambda} = \frac{c_\gamma}{\Lambda} \frac{g_A}{\Lambda} = \frac{c_\gamma}{\Lambda} \frac{g_A}{\Lambda}
\]
and its physical value i.e. we take the SU(4) relation
\[
\frac{c_\gamma}{\Lambda} = c_A \frac{c_\gamma}{\Lambda} \frac{g_A}{\Lambda} = \frac{c_\gamma}{\Lambda} \frac{g_A}{\Lambda} = \frac{c_\gamma}{\Lambda} \frac{g_A}{\Lambda}
\]
In order to assess cut-off effects we use the simulations at three lattice spacings at the smallest and largest pion mass used in this work. We take as reference pion mass the one computed on the finest lattice and interpolate results at the other two \( \beta \)-values to these two reference masses. In Fig. 6(i) we show the value of \( g_A \) at these reference pion masses computed in units of \( r_0 \). We perform a fit to these data using a linear form
\[
g_A(a) = g_A(0) + c(a/r_0)^2
\]
The resulting fit is shown in Fig. 6(ii). Setting \( c = 0 \) we obtained the constant line also shown in the figure. As can be seen, for both large and small pion masses the slope is consistent with zero yielding a value in the continuum limit in agreement with the constant fit. Therefore we conclude that finite \( a \) effects are negligible and for the intermediate pion masses we obtained the values in the continuum by fitting our data at \( \beta = 3.9 \) and \( \beta = 4.05 \) to a constant.

| \( r_0/m_\pi \) | \( g_A(\beta = 3.9) \) | \( g_A(\beta = 4.05) \) | \( g_A(\beta = 4.2) \) | \( g_A(a \to 0) \) | \( g_A(L \to \infty, a \to 0) \) |

The values for \( g_A \) found at six reference pion masses are given in Table IV. We give both the continuum values obtained using a constant fit when no volume corrections are carried out as well as with the volume corrected data. The volume corrected data extrapolated to \( a = 0 \) are plotted in Fig. 7.

\[
g_A(m_\pi^2) = g_A^0 - \frac{(g_A^0)^3 m_\pi^2}{16\pi^2 f_\pi^2} + 4 \left( C_{\text{SSE}}(\lambda) + \frac{c_\gamma^2}{4\pi^2 f_\pi^2} \left[ \frac{155}{972} g_1 - \frac{17}{36} g_A^0 \right] + \frac{\gamma}{\lambda} \ln \frac{m_\pi}{\Lambda} \right) m_\pi^2 + \frac{4 c_A^2 g_\pi^0}{27\pi^2 f_\pi^2} m_\pi^2 + \frac{8}{27\pi^2 f_\pi^2} c_A^2 g_A^0 m_\pi^2 R(m_\pi) + \frac{c_\gamma^2 \Delta_0^2}{81\pi^2 f_\pi^2} (25 g_1 - 57 g_A^0) \ln \frac{2 \Delta_0}{m_\pi} - R(m_\pi) + O(\epsilon^4) \] (17)

with
\[
\gamma = \frac{1}{16\pi^2 f_\pi^2} \left[ \frac{50}{81} c_A g_\pi - \frac{1}{2} g_A^0 - \frac{2}{9} c_A^2 g_A^0 - (g_A^0)^3 \right]
\]

\[
R(m_\pi) = \sqrt{1 - \frac{m_\pi}{\Delta_0} \left[ \frac{\Delta_0}{m_\pi} + \frac{\Delta_0^2}{m_\pi^2} - 1 \right]} . \] (18)

The three parameters to fit are \( g_A^0 \), the value of the axial charge at the chiral point, the \( \Delta \) axial coupling...
constant $g_1$ and a counter-term $C_{SSE}(\lambda)$. We again take
the nucleon to $\Delta$ axial coupling constant $c_A = 1.5$, the
mass splitting between the $\Delta$ and the nucleon at the
chiral limit, $\Delta p = 0.2711$ and $\lambda = 1$ GeV. Fitting the
volume corrected continuum results we find $g_A = 1.12(8)$,
$g_1 = 2.37(1.52)$ and $C_{SSE} = - 1.01(2.01)$. The parameters
$g_1$ and $C_{SSE}$ are highly correlated explaining the
resulting large error band. Fitting the lattice without
any volume correction and without extrapolating to the
continuum limit we obtained $g_A = 1.08(8)$, $g_1 = 2.02(1.21)$
and $C_{SSE} = - 0.63(1.57)$ which are consistent with the
continuum volume corrected results. This shows that
both cut-off and volume artifacts are small as compared
to the uncertainty due to the chiral extrapolation.

B. Axial form factors

In this section we discuss the results obtained for the
axial form factors $G_A(Q^2)$ and $G_p(Q^2)$.

To assess cut-off effects we compare in Fig. 8 results for
$G_A(Q^2)$ and $G_p(Q^2)$ versus $Q^2$ for three different lattice
spacings at a similar pion mass of about 470 MeV. As
can be seen, results at these three lattice spacings are
consistent indicating that cut-off effects are negligible for
these lattice spacings. We perform a dipole fit to $G_A(Q^2)$
using

$$G_A(Q^2) = \frac{g_A}{(1 + Q^2/\lambda^2)^2}, \quad (19)$$

with a momentum upper range of $Q^2 \sim 1.5$ GeV$^2$. The
axial mass $m_A^\text{exp}$ of the fits is larger than in experimental
value of $m_A^\text{exp} = 1.1$ GeV extracted from the best
dipole fit to the electroproduction data. This is evident from
the smaller slope shown by the lattice data both for
twisted mass fermions and domain wall fermions. Assum-

FIG. 7: The nucleon axial charge obtained by taking the con-
tinuum limit of the volume corrected data. The shaded area
shows the best fit to the data shown on the graph. The dashed
line shows the best fit to the raw lattice data at the three val-
ues of $\beta$ with the dotted lines being the associate error band.

FIG. 8: The nucleon axial form factors $G_A(Q^2)$ and $G_p(Q^2)$
at $m_\pi \sim 470$ MeV at $\beta = 3.9$ (filled red circles), 4.05 (filled
green triangles) and 4.2 (yellow squares) versus $Q^2$. The line
is the result of a dipole fit (to the form given in Eq. (20))
$G_A(Q^2) (G_p(Q^2))$ data on the coarse lattice.

ing the partially conserved axial current relation and pion
pole dominance we can relate the form factor $G_p(Q^2)$ to
$G_A(Q^2)$:

$$G_p(Q^2) = G_A(Q^2) \frac{G_p(0)}{Q^2 + m_p^2}. \quad (20)$$

The dependence of these form factors on the pion mass
is seen in Fig. 9 where we show both $G_A$ and $G_p$ com-
puted at several values of the pion mass spanning a range
from about 470 MeV to 300 MeV at $\beta = 3.9$. We show fits
to the lattice data using a dipole form as given in Eq. (19)
for $G_A(Q^2)$ and to the form given in Eq. (20) for $G_p(Q^2)$,
which described the data rather well. Although the mass
dependency is weak and the general trend is to approach
experiment, lattice data show a weaker $Q^2$ dependence
as compared to experiment. As already pointed out, the
best dipole fit to the electroproduction data yields an
axial mass $m_A^\text{exp} = 1.1$ GeV [5], and it is shown by the
solid line. The experimental line in the case of $G_p(Q^2)$
shown in Fig. 9 is obtained using Eq. (20) and pion mass
of $m_p = 135$ MeV.

In Fig. 10 we check for finite volume effects by compar-
ing results obtained at $\beta = 3.9$ on a lattice of spatial
length $L = 2.8$ fm and $L = 2.1$ fm at $m_\pi \sim 300$ MeV.
As can be seen volume effects are negligible for $G_A$. In
the case of $G_p$ we have a strong dependence on $Q^2$ as
$Q^2 \to 0$ because of the pion pole dependence expected for this form factor. Therefore the fits are strongly dependent on the lowest values of $Q^2$ that are available. E.g. discarding the point at the lowest momentum yield the dotted lines which are steeper as compared to including it. Although there is an overall consistency between the two data sets at $\beta = 3.9$ deviations are seen in the fits when the same momentum range is used. The fit using the whole range of data obtained on the smaller lattice, shown by the dashed red line exhibit a weaker dependence as compared to the fit using the results on the larger lattice but discarding the point at the lowest momentum, shown by the dotted blue line. In Figs. [11] and [12] we compare our results with the results by LHPC which were obtained in a mixed action approach that uses DWF on staggered sea quarks [31] on a lattice with $L = 3.5$ fm. The results are in agreement in the case of $G_A(Q^2)$, while in the case of $G_P(Q^2)$ there are larger discrepancies. Given the mass dependence of $G_P(Q^2)$ shown in Fig. [9] a difference in the pion mass of 50 MeV cannot fully account for this. Such discrepancies may indicate that volume effects are not negligible on form factors such as $G_P(Q^2)$ which are strongly affected by the pion-pole.

In the case of $G_P(Q^2)$ one can extract the fit parameters $G_P(0)$ and $m_p$ by either fitting the ratio of $G_P/G_A$ using the whole range of data obtained on the smaller lattice, shown by the dashed red line exhibit a weaker dependence as compared to the fit using the results on the larger lattice but discarding the point at the lowest momentum, shown by the dotted blue line. In Figs. [11] and [12] we compare our results with the results by LHPC which were obtained in a mixed action approach that uses DWF on staggered sea quarks [31] on a lattice with $L = 3.5$ fm. The results are in agreement in the case of $G_A(Q^2)$, while in the case of $G_P(Q^2)$ there are larger discrepancies. Given the mass dependence of $G_P(Q^2)$ shown in Fig. [9] a difference in the pion mass of 50 MeV cannot fully account for this. Such discrepancies may indicate that volume effects are not negligible on form factors such as $G_P(Q^2)$ which are strongly affected by the pion-pole.

In the case of $G_P(Q^2)$ one can extract the fit parameters $G_P(0)$ and $m_p$ by either fitting the ratio of $G_P/G_A$ using the whole range of data obtained on the smaller lattice, shown by the dashed red line exhibit a weaker dependence as compared to the fit using the results on the larger lattice but discarding the point at the lowest momentum, shown by the dotted blue line. or use the fitted values for \(G_A(q^2)\) and fit to the form of Eq. (20). The values extracted by performing these fits are compatible within error bars. Our lattice data on \(G_p(q^2)\) are flatter than pion-pole dominance predicts requiring a larger pole mass \(m_p\) than the pion mass measured on the lattice. In Table VII we tabulate the resulting fitting parameters for all \(\beta\) and \(\mu\) values. The parameters \(G_p(0)\) and \(m_p\) have been extracted from fits to the form given in Eq. (20). The full set of our lattice results on \(G_A(q^2)\) and \(G_p(Q^2)\) is given in the Tables VI-VIII of the Appendix.

\[G_p(Q^2)\]

\[\beta = 3.9\]

\[\beta = 4.05\]

\[\beta = 4.2\]

\[\beta = 3.9\]

TABLE V: Results on the axial nucleon charge and axial mass extracted by fitting \(G_A(Q^2)\) to a dipole form. The two last column give the \(G_p(0)\) and the mass \(m_p\) by fitting \(G_p(Q^2)\) to the form given in Eq. (20).

FIG. 12: Induced pseudo-scalar form factor \(G_p(Q^2)\) as a function of \(Q^2\). \(N_F = 2\) TMF results at \(m_\pi = 298\) MeV are shown with filled squares and \(N_F = 2 + 1\) using a mixed action of DWF and staggered sea quarks at \(m_\pi = 356\) MeV are shown with triangles. The solid line is obtained using the parametrization of experimental electroproduction results for \(G_A\) and pion-pole dominance.

IV. CONCLUSIONS

Using \(N_F = 2\) twisted mass fermions we obtain accurate results on the axial \(G_A(Q^2)\), and \(G_p(Q^2)\) form factors as a function of \(Q^2\) for pion masses in the range of about 260-470 MeV. The general feature is a flatter dependence on \(Q^2\) than experiment. This is a feature also seen in the electromagnetic nucleon form factors. Finite volume effects are found to be small on \(G_A\). Our results are in agreement with recent results obtained using other lattice fermions such as dynamical \(N_F = 2 + 1\) domain wall fermions. Having results at three lattice spacings enables us to take the continuum limit. We find that cut-off effects are small for the values of the lattice spacings used in this work. Performing a chiral extrapolation of our continuum results for the nucleon axial charge, we find at the physical point the value \(g_A = 1.12(8)\). This is one standard deviation lower than the physical value. The large error associated with our determination of \(g_A\) is mostly due to the chiral extrapolation. Therefore it is crucial to perform an analysis with a pion mass closer to its physical value.

Acknowledgments

We would like to thank all members of ETMC for a very constructive and enjoyable collaboration and for the many fruitful discussions that took place during the development of this work.

Numerical calculations have used HPC resources from GENCI (IDRIS and CINES) Grant 2009-052271 and CC-IN2P3 as well as from the John von Neumann-Institute for Computing on the JUMP and Jugene systems at the research center in Jülich. We thank the staff members for their kind and sustained support. M.Papinutto acknowledges financial support by the Marie Curie European Reintegration Grant of the 7th European Community Framework Programme under contract number PERG05-GA-2009-249309. This work is supported in part by the DFG Sonderforschungsbereich/Transregio SFB/TR9 and by funding received from the Cyprus Research Promotion Foundation under contracts EPYAN/0506/08, KY-G/0907/11/ and TECHNOLOGY/ΘΕΠΙΣ/0308(BE)/17.
