This paper is dedicated to Nico Temme on the occasion of his 65th birthday.

Abstract

An explicit structure relation for Askey-Wilson polynomials is given. This involves a divided $q$-difference operator which is skew symmetric with respect to the Askey-Wilson inner product and which sends polynomials of degree $n$ to polynomials of degree $n+1$. By specialization of parameters and by taking limits, similar structure relations, as well as lowering and raising relations, can be obtained for other families in the $q$-Askey scheme and the Askey scheme. This is explicitly discussed for Jacobi polynomials, continuous $q$-Jacobi polynomials, continuous $q$-ultraspherical polynomials, and for big $q$-Jacobi polynomials. An already known structure relation for this last family can be obtained from the new structure relation by using the three-term recurrence relation and the second order $q$-difference formula. The results are also put in the framework of a more general theory. Their relationship with earlier work by Zhedanov and Bangerezako is discussed. There is also a connection with the string equation in discrete matrix models and with the Sklyanin algebra.

1 Introduction

One of the many ways to characterize a family $\{p_n(x)\}$ of classical orthogonal polynomials (Jacobi, Laguerre and Hermite polynomials) is by a structure relation

$$\pi(x)p'_n(x) = a_np_{n+1}(x) + b_np_n(x) + c_np_{n-1}(x),$$

where $\pi(x)$ is a fixed polynomial (necessarily of degree $\leq 2$). In view of the three-term recurrence relation this is equivalent to a characterization by a lowering relation

$$\pi(x)p'_n(x) = (\alpha_n x + \beta_n)p_n(x) + \gamma_np_{n-1}(x)$$

(1.2)
or to a characterization by a raising relation
\[ \pi(x) p'_n(x) = (\tilde{\alpha}_n x + \tilde{\beta}_n) p_n(x) + \tilde{\gamma}_n p_{n+1}(x). \] (1.3)

The lowering relation (1.2) was given in [7, 10.7(4)] (in [7, 10.8(15)] explicitly for Jacobi polynomials), where it was attributed to Tricomi (1948). The characterization of classical orthogonal polynomials by their property (1.2) (and thus equivalently by their property (1.1)) was first given by Al-Salam & Chihara [2]. See also [16] for a characterization by (1.1). Note that the lowering and raising relations (1.2), (1.3) are different from the more familiar shift operator relations, where not only the degree is lowered or raised, but also the parameters are shifted. These formulas are well known for all orthogonal polynomials in the \((q-\)Askey scheme, see for instance [14].

Orthogonal polynomials satisfying the more general structure relation
\[ \pi(x) p'_n(x) = \sum_{j=n-s}^{n+t} a_{n,j} p_j(x) \quad (\pi(x) \text{ a polynomial}; \ s, t \text{ independent of } n). \] (1.4)

are called semi-classical, see Maroni [17]. According to [2] the question to characterize orthogonal polynomials satisfying (1.4) was first posed by R. Askey.

García, Marcellán & Salto [8] characterized discrete classical orthogonal polynomials in the Hahn class (Hahn, Krawtchouk, Meixner and Charlier polynomials) by a structure relation similar to (1.1), with the derivative replaced by the difference operator \((\Delta f)(x) := f(x+1) - f(x)\). Next Medem, Álvarez-Nodarse & Marcellán [18] (see also [3]) characterized the orthogonal polynomials in the \(q\)-Hahn class by a structure relation obtained from (1.1) by replacing the derivative by the \(q\)-derivative \(D_q\), where
\[ (D_q f)(x) = D_{q,x}(f(x)) := \frac{f(x) - f(qx)}{(1-q)x}. \] (1.5)

Here a family of orthogonal polynomials \(p_n(x)\) is in the \(q\)-Hahn class if the polynomials \((D_q p_n)(x)\) are again orthogonal.

Variants of lowering and raising relations (1.2), (1.3) are scattered over the literature. See a brief survey in [15]. Note in particular the lowering and raising relations for \(A_n\) type Macdonald polynomials given by Kirillov & Noumi [13]. The \(A_1\) case yields lowering and raising relations for continuous \(q\)-ultraspherical polynomials. A lowering relation for continuous \(q\)-Jacobi polynomials was given by Ismail [12, Theorem 15.5.2].

For Askey-Wilson polynomials, a structure relation was given in a very implicit way by Zhedanov [24] (see my discussion in Remark 2.6), while a lowering and raising relation was given by Bangerezako [5] (see my discussion
after (4.13)). The main result of the present paper gives a structure relation for Askey-Wilson polynomials in the form

$$Lp_n = a_n p_{n+1} + c_n p_{n-1},$$  \hspace{1cm} (1.6)

where $L$ is a linear operator which is skew symmetric with respect to the inner product $\langle , \rangle$ for which the Askey-Wilson polynomials are orthogonal:

$$\langle Lf, g \rangle = -\langle f, Lg \rangle.$$  \hspace{1cm} (1.7)

This operator is explicitly given by

$$(Lf)[z] := \left( (1 - az)(1 - bz)(1 - c z)(1 - d z) z^{-2} f[qz] \right. \\
- \left. (1 - a/z)(1 - b/z)(1 - c/z)(1 - d/z) z^2 f[q^{-1}z] \right) (z - z^{-1})^{-1}.$$  \hspace{1cm} (1.8)

It sends symmetric Laurent polynomials of degree $n$ to symmetric Laurent polynomials of degree $n+1$. By specialization and limit transition a structure relation of the form (1.6) with $L$ satisfying (1.7) can be obtained for all families of orthogonal polynomials in the $q$-Askey scheme and the Askey scheme (a list of these families is given in [14]). For instance, for Jacobi polynomials $P_n^{(\alpha, \beta)}(x)$ we get for the operator $L$:

$$(Lf)(x) := (1 - x^2)f'(x) - \frac{1}{2}(\alpha - \beta + (\alpha + \beta + 2)x)f(x)$$

$$= (1 - x)^{-\frac{1}{2}(\alpha + \beta + 1)}(1 + x)^{\frac{1}{2}(\alpha + \beta + 1)} \frac{d}{dx} \left( (1 - x)^{\frac{1}{2} \alpha + 1} (1 + x)^{\frac{1}{2} \beta + 1} f(x) \right).$$  \hspace{1cm} (1.9)

$$= (DX - XD)f(x),$$  \hspace{1cm} (1.11)

where $X$ is multiplication by $x$ and $D$ is a second order differential operator having the Jacobi polynomials as eigenfunctions (see (3.6)). It will turn out that the form (1.10) of $L$, involving something close to the square root of the weight function, can also be realized higher up in the ($q$-)Askey scheme, notably in the Askey-Wilson case (1.8). It will also turn out that the form (1.11) of $L$, i.e., as a commutator of $X$ and a second order differential or ($q$-)difference operator $D$ having the orthogonal polynomials as eigenfunctions, persists in the ($q$-)Askey scheme. In fact, there is an essentially one-to-one relationship between operators $L$ and $D$.

For those families where a structure relation had been given earlier, one can relate that formula to (1.6) by use of the three-term recurrence relation, and sometimes also of the second-order ($q$-)difference equation.

The general theory of the structure relation of the form (1.6) with skew symmetric $L$ will be given in [2]. This theory is easy and elegant. The coefficients in the resulting structure relation and in the lowering and raising relations are very close to the coefficients in the three-term recurrence
relation. In §2 I will also discuss the relationship with bispectral problems (Grünbaum and Haine), Zhedanov’s algebra, and the string equation in the context of discrete matrix models. The case of Jacobi polynomials will be discussed in §3. The main result, the Askey-Wilson case, is the topic of §4. Here also a connection with the Sklyanin algebra will be made. In §5 this is specialized to the case of continuous $q$-Jacobi polynomials and we show that it has the results for Jacobi polynomials as a limit case. A further specialization to continuous $q$-ultraspherical polynomials is given in §6, and the resulting structure relation is related to another one obtained from results in [15]. Finally, in §7, we take the limit of the Askey-Wilson case to the case of big $q$-Jacobi polynomials, and we relate the resulting structure relation to the one in [18].

Acknowledgement I thank G. Bangerezako, L. Haine, H. Rosengren, P. van Moerbeke and the referees for helpful comments.

Conventions Throughout assume that $0 < q < 1$. For $(q)$-Pochhammer symbols and $(q)$-hypergeometric series use the notation of Gasper & Rahman [9]. Symmetric Laurent polynomials $f(z) = \sum_{k=-n}^{n} c_k z^k$ (where $c_k = c_{-k}$) are related to ordinary polynomials $f(x)$ in $x = \frac{1}{2}(z + z^{-1})$ by $f(\frac{1}{2}(z + z^{-1})) = f[z]$.

## 2 The general form of the structure relation

Suppose we have a family of orthogonal polynomials $p_n(x)$ with respect to an orthogonality measure $\mu$ on $\mathbb{R}$:

$$p_n(x) = k_n x^n + \cdots, \quad \langle p_n, p_m \rangle = h_n \delta_{n,m},$$

(2.1)

where

$$\langle f, g \rangle := \int_{\mathbb{R}} f(x) g(x) \, d\mu(x).$$

(2.2)

Write the three-term recurrence relation as

$$xp_n(x) = A_n p_{n+1}(x) + B_n p_n(x) + C_n p_{n-1}(x).$$

(2.3)

Then

$$A_n = \frac{k_n}{k_{n+1}}, \quad C_n = \frac{k_{n-1}}{k_n} \frac{h_n}{h_{n-1}} = A_{n-1} \frac{h_n}{h_{n-1}}.$$

(2.4)

The proof of the following proposition is straightforward.

**Proposition 2.1.** Let $L$ be a linear operator acting on the space $\mathbb{R}[x]$ of polynomials in one variable with real coefficients such that $L$ is skew symmetric with respect to the inner product (2.2) (i.e., (1.7) holds) and such that

$$L(x^n) = \gamma_n x^{n+1} \text{ terms of lower degree},$$

(2.5)
where $\gamma_n \neq 0$. Then the following structure relation and lowering and raising relations hold:

\[
(Lp_n)(x) = \gamma_n A_p n_{n+1}(x) - \gamma_{n-1} C_p n_{n-1}(x),
\]

\[
-\gamma_n(x - B_n)p_n(x) + (Lp_n)(x) = - (\gamma_n + \gamma_{n-1})C_p n_{n-1}(x),
\]

\[
\gamma_{n-1}(x - B_n)p_n(x) + (Lp_n)(x) = (\gamma_n + \gamma_{n-1})A_p n_{n+1}(x).
\]

Skew symmetric operators $L$ as above can be produced from symmetric operators $D$ which have the $p_n$ as eigenfunctions. First note that

\[
(Xf)(x) := xf(x)
\]

defines a symmetric operator $X$ on $\mathbb{R}[x]$ with respect to the inner product \eqref{inner_product}, i.e., $\langle Xf, g \rangle = \langle f, Xg \rangle$. Now the following proposition can be shown immediately.

**Proposition 2.2.** Let $D$ be a linear operator acting on $\mathbb{R}[x]$ which is symmetric with respect to the inner product \eqref{inner_product}, i.e., $\langle Df, g \rangle = \langle f, Dg \rangle$, and which satisfies

\[
D(x^n) = \lambda_n x^n + \text{terms of lower degree},
\]

where $\lambda_n \neq \lambda_{n-1}$, so $p_n$ is an eigenfunction of $D$:

\[
Dp_n = \lambda_n p_n.
\]

Then the commutator

\[
L := [D, X] = DX - XD
\]

is skew symmetric with respect to the inner product \eqref{inner_product} and satisfies \eqref{structure_relation} with

\[
\gamma_n = \lambda_{n+1} - \lambda_n \neq 0.
\]

So $L$ also satisfies the structure relation \eqref{structure_relation}.

In fact, we can reverse Proposition 2.2. From skew symmetric $L$ as in Proposition 2.1 we can produce symmetric $D$ as in Proposition 2.2 and $D$ is uniquely determined by $L$ up to a term which is constant times identity.

**Proposition 2.3.** Let $L$ be as in Proposition 2.1. Define a linear operator $D$ on $\mathbb{R}[x]$ by its action on monomials:

\[
D(1) = 0, \quad D(x^n) = \sum_{k=0}^{n-1} X^k L(x^{n-k-1}).
\]

Then $D$ satisfies the properties of Proposition 2.2 with $\lambda_0 = 0$. Any other operator $D$ satisfying \eqref{structure_relation} and having $1$ as eigenfunction differs from $D$ given by \eqref{monomial_action} by a constant times identity.
Proof  Formula (2.12) acting on $x^n$ follows directly from (2.14). From (2.5) together with $DX = L + XD$ acting on $x^n$ we see by induction that (2.10) holds with $\lambda_n$ satisfying (2.13). In order to prove that $D$ is symmetric, observe that, for $n > 0$, 

$$
\langle Dx^n, x^m \rangle - \langle x^n, Dx^m \rangle = \langle DX x^{n-1}, x^m \rangle - \langle x^{n-1}, XD x^m \rangle
$$

$$
= ((L + XD)x^{n-1}, x^m) + \langle x^{n-1}, (L - DX)x^m \rangle
$$

$$
= \langle Dx^{n-1}, x^{m+1} \rangle - \langle x^{n-1}, Dx^{m+1} \rangle.
$$

Hence

$$
\langle Dx^{n+m}, 1 \rangle = \langle Dx^n, x^m \rangle - \langle x^n, Dx^m \rangle = -\langle 1, Dx^{n+m} \rangle.
$$

So $\langle Dx^{n+m}, 1 \rangle = 0$ and $\langle Dx^n, x^m \rangle = \langle x^n, Dx^m \rangle$.

Finally, for the uniqueness, let $D_1$ and $D_2$ satisfy (2.11) and and let them have 1 as eigenfunction. Then $D_1 - D_2$ commutes with $X$. Hence

$$(D_1 - D_2)(x^n) = (D_1 - D_2)(1) = X^n(c1) = cx^n.$$

Remark 2.4. If $L$ satisfies (2.12) and $D$ satisfies (2.11) then the lowering and raising relations (2.7) and (2.8) are preserved if we add to their left-hand sides a term $g(x)(D - \lambda_n)p_n(x)$, where $g(x)$ is any function.

Remark 2.5. Van Moerbeke [22, §7] (also jointly with Adler in [1, §5]) gives explicit skew symmetric first order differential operators $L$ ($Q$ in his notation) satisfying Proposition 2.1 for the case of Jacobi, Laguerre and Hermite polynomials. More generally he gives these operators if the weight function is perturbed by multiplying the weight function with $\exp(\sum_{j=1}^{\infty} t_j x^j)$ (only finitely many $t_j$ nonzero). Then (2.5) and (2.6) are no longer valid, but the right-hand side of (2.6) has to be replaced by some linear combination of orthogonal polynomials $p_k(x)$ with coefficients depending on the $t_j$. In all these cases $L$ satisfies the so-called string equation

$$
[X, L] = f_0(X)
$$

with $f_0$ a polynomial given by $f_0(X) = 1 - X^2$, $X$, 1 for Jacobi, Laguerre and Hermite polynomials, respectively, and for their deformations. This is inspired by the matrix models of the physicists, where the Hermite case occurs, see Witten [23, §4c], in particular (4.43), (4.53), (4.65), (4.66).

Remark 2.6. The structure relation (2.6) can be written in a form which is symmetric with respect to the variables $n$ and $x$. Write $p(n, x)$ instead of $p_n(x)$. Define operators $J$ and $\Lambda$ acting on functions on $\mathbb{Z}_{\geq 0}$ by

$$
(J\phi)(n) := A_n\phi(n + 1) + B_n\phi(n) + C_n\phi(n - 1),
$$

$$
(\Lambda\phi)(n) := \lambda_n\phi(n).
$$
Now use (2.9), (2.12), (2.3) and (2.11) in order to rewrite (2.6) as
\[
([D, X] p(n, .))(x) = ([J, \Lambda] p(., x))(n).
\] (2.18)

This equation essentially occurs in Duistermaat & Grünbaum [6, (1.7)] and Grünbaum & Haine [10, (3)], where they study the bispectral problem with $D$ a differential operator and $n$ continuous respectively discrete.

For $p_n$, $D$ and $\lambda_n$ $q$-dependent, a $q$-analogue of (2.18) has been considered in the literature which involves $q$-commutators instead of ordinary commutators:
\[
\left(\left(q^{\frac{1}{2}} D X - q^{-\frac{1}{2}} X D\right) p(n, .)\right)(x) = \left(\left(q^{\frac{1}{2}} J \Lambda - q^{-\frac{1}{2}} \Lambda J\right) p(., x)\right)(n).
\] (2.19)

In fact, in Zhedanov [24] formulas (1.4) and (1.8a) may be interpreted as formulas (2.11) and (2.3) in the present paper, respectively. Then formula (1.8b) together with (1.1a) in [24] can be interpreted as (2.19) above. See also Grünbaum & Haine [11] on the bispectral problem in the $q$-case, where some formulas in section 3 may be close to (2.19) above.

Formula (1.1c) in [24] may be interpreted as the $q$-commutator $q^{\frac{1}{2}} XL - q^{-\frac{1}{2}} LX$ being equal to a linear combination of $X$, $D$ and $L$. A similar formula is observed in [11, (2.4)], where it is called the $q$-string equation as a $q$-analogue of the string equation (2.15).

3 Jacobi polynomials

Jacobi polynomials $P_n(x) = P_n^{(\alpha, \beta)}(x)$ (see [7, §10.8]) are orthogonal with respect to the inner product
\[
\langle f, g \rangle = \int_{-1}^{1} f(x) g(x) (1 - x)^\alpha (1 + x)^\beta \, dx \quad (\alpha, \beta > -1).
\]

The coefficients in the three-term recurrence relation (2.3) are
\[
A_n = \frac{2(n + 1)(n + \alpha + \beta + 1)}{(2n + \alpha + \beta + 1)(2n + \alpha + \beta + 2)}, \quad (3.1)
\]
\[
B_n = \frac{\beta^2 - \alpha^2}{(2n + \alpha + \beta)(2n + \alpha + \beta + 2)}, \quad (3.2)
\]
\[
C_n = \frac{2(n + \alpha)(n + \beta)}{(2n + \alpha + \beta)(2n + \alpha + \beta + 1)}. \quad (3.3)
\]

For the operator $L$ given by (1.9) we see immediately that (2.5) holds with
\[
\gamma_n = -\frac{1}{2}(2n + \alpha + \beta + 2). \quad (3.4)
\]
and that the skew symmetry (1.7) holds. Hence, by Proposition 2.1, the
structure relation (2.6) is valid. Explicitly it reads as follows:

\[
\left((1-x^2)\frac{d}{dx} - \frac{1}{2}(\alpha - \beta + (\alpha + \beta + 2)x)\right)P_n^{(\alpha,\beta)}(x) = -\frac{(n+1)(n+\alpha+\beta+1)}{2n+\alpha+\beta+1}P_{n+1}^{(\alpha,\beta)}(x) + \frac{(n+\alpha)(n+\beta)}{2n+\alpha+\beta+1}P_n^{(\alpha,\beta)}(x). \tag{3.5}
\]

We can also make explicit formulas (1.11) and (2.13) with

\[
D = \frac{1}{2}(1-x^2)\frac{d^2}{dx^2} + \frac{1}{2}(\beta - \alpha - (\alpha + \beta + 2)x)\frac{d}{dx}, \quad \lambda_n = -\frac{1}{2}n(n+\alpha+\beta+1). \tag{3.6}
\]

Formula (3.5) can be combined with the three-term recurrence relation
in order to obtain the structure relation of the form (1.1):

\[
(1-x^2)\frac{d}{dx}P_n^{(\alpha,\beta)}(x) = -\frac{2n(n+1)(n+\alpha+\beta+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)}P_{n+1}^{(\alpha,\beta)}(x) + \frac{2n(n+\alpha+\beta+1)(\alpha - \beta)}{(2n+\alpha+\beta)(2n+\alpha+\beta+2)}P_n^{(\alpha,\beta)}(x) + \frac{2(n+\alpha)(n+\beta)(n+\alpha+\beta+1)}{(2n+\alpha+\beta)(2n+\alpha+\beta+1)}P_{n-1}^{(\alpha,\beta)}(x). \tag{3.7}
\]

4 Askey-Wilson polynomials

Askey-Wilson polynomials (see [4], [9, §7.5], [14, §3.1]) are defined by

\[
p_n[z] = p_n\left(\frac{1}{2}(z + z^{-1})\right) = p_n\left(\frac{1}{2}(z + z^{-1}); a, b, c, d \mid q\right) = \frac{(ab, ac, ad; q)_n}{a^n} \phi_3\left(q^{-n}, q^{-n-1}abcd, az, az^{-1}; ab, ac, ad; q, q\right). \tag{4.1}
\]

If \(a, b, c, d \in \mathbb{C}\) satisfy

\[
a^2, b^2, c^2, d^2, ab, ac, ad, bc, bd, cd \notin \{q^{-k} \mid k = 0, 1, 2, \ldots\} \tag{4.2}
\]

then these polynomials satisfy the orthogonality relation

\[
\langle f, g \rangle := \frac{1}{4\pi i} \oint_C f[z] g[z] w(z) \frac{dz}{z}, \tag{4.3}
\]

\[
w(z) := \frac{(z^2, z^{-2}; q)_\infty}{(az, az^{-1}, bz, bz^{-1}, cz, cz^{-1}, dz, dz^{-1}; q)_\infty}, \tag{4.4}
\]

where \(C\) is the unit circle traversed in positive direction with suitable de-
formations to separate the sequences of poles converging to zero from the
sequences of poles diverging to \(\infty\). If \(a, b, c, d\) are four reals, or two reals
and one pair of complex conjugates, or two pairs of complex conjugates such that $|ab|, |ac|, |ad|, |bc|, |bd|, |cd| < 1$, then the Askey-Wilson polynomials are real-valued and their orthogonality can be rewritten as an integral over $x = \frac{1}{2}(z + z^{-1}) \in [-1, 1]$ plus a finite sum over real $x$-values outside $[-1, 1]$. This finite sum does not occur if $|a|, |b|, |c|, |d| < 1$.

Now $k_n, h_n, B_n, D$ and $\lambda_n$ in (4.2) can be specified for the Askey-Wilson case as follows.

$$k_n = 2^n(abcdq^{n-1}; q)_n, \quad h_n = \frac{1 - abcdq^{-1}}{1 - abcdq^{2n-1}} \frac{(q, ab, ac, ad, bc, bd, cd; q)_n}{(abcd^{-1}; q)_n},$$

$$B_n = \left((a + b + c + d)(q - abcdq^{n-1} - abdq^n + abcdq^{2n}) + (bcd + abd + acd + abc)(1 - q^n - q^{n+1} + abcdq^{2n-1})\right) \times \frac{q^{n-1}}{2(1 - abcdq^{2n-2})(1 - abdq^{2n})}, \quad (4.5)$$

$$Dp_n = \lambda_n p_n, \text{ where}$$

$$\frac{1}{2}(1 - q^{-1})(Df)[z] = v(z)f[qz] - (v(z) + v(z^{-1}))f[z] + v(z^{-1})f[q^{-1}z],$$

$$v(z) = \frac{(1 - az)(1 - bz)(1 - cz)(1 - dz)}{(1 - z^2)(1 - qz^2)},$$

$$\frac{1}{2}(1 - q^{-1})\lambda_n = (q^{-n} - 1)(1 - abcdq^{n-1}). \quad (4.6)$$

Define an operator $L$ acting on symmetric Laurent polynomials:

$$(Lf)[z] := \left((1 - az)(1 - bz)(1 - cz)(1 - dz) z^{-2} f[qz] - (1 - a/z)(1 - b/z)(1 - c/z)(1 - d/z) z^2 f[q^{-1}z]\right) (z - z^{-1})^{-1} \quad (4.7)$$

$$= \frac{1}{2}(1 - q^2) \frac{(aqz^{-1}, qz^{-1}; bsz^{-1})}{(qz^2, qz^{-2}; q^2)_\infty} (qz^2, qz^{-2}; q^2)_\infty f[z] \times \frac{\partial^2}{\partial z^2} \left( (gaz, qaz^{-1}, qbz, qbz^{-1}, qcz, qcz^{-1}, qdz, qdz^{-1}, q^2)_\infty \right). \quad (4.8)$$

Here

$$\frac{\partial^2}{\partial q^2} q[z] := \frac{2(g[q^{1/2}z] - g[q^{-1/2}z])}{(q^{1/2} - q^{1/2})(z - z^{-1})} \quad (4.9)$$

is a divided $q$-difference operator (see [4, §5]). It tends to $\frac{d^2}{dx^2} g(x)$ as $q \uparrow 1$.

Then $L$ sends symmetric Laurent polynomials of degree $n$ to symmetric Laurent polynomials of degree $n + 1$,

$$\gamma_n = 2(abcdq^n - q^{-n}), \quad (4.10)$$
and \( L \) is skew symmetric with respect to the inner product (4.3), so (1.7) holds. For the proof of (1.7) note that

\[
\int_C \frac{(1 - az)(1 - bz)(1 - cz)(1 - dz)f[qz]g[z]}{z^2(z - z^{-1})} w(z) \frac{dz}{z} = \int_C \frac{f[z]g[q^{-1}z]}{(az, qaz^{-1}, qcz, cz)} \frac{dz}{z}.
\]

(Actually, the contour deformation above can be done with avoidance of poles in the generic case of complex \( a, b, c, d \) such that the four line segments connecting \( a, b, c, d \) with 0 avoid the four halflines \( \{ ta^{-1}, tb^{-1}, tc^{-1}, td^{-1} | t \geq 1 \} \).) Alternatively, we can observe that \( L = [D, X] \), \( \gamma_n = \lambda_{n+1} - \lambda_n \) with \( D, \lambda_n \) given by (4.6), and apply Proposition 2.2.

By Proposition 2.1 we have the structure relation (2.6), which can be more explicitly written (with usage of (1.7)) as

\[
(Lp_n)[z] = -\frac{(1 - abcdq^{n-1})p_{n+1}[z]}{q^n(1 - abcdq^{2n-1})} + (1 - abq^{n-1})(1 - acq^{n-1})(1 - adq^{n-1}) \times (1 - bcq^{n-1})(1 - bdq^{n-1})(1 - cdq^{n-1}) \cdot \frac{(1 - q^n)p_{n-1}[z]}{q^{n-1}(1 - abcdq^{2n-2})}. \tag{4.11}
\]

We can also write the lowering and raising relations (2.7), (2.8) more explicitly (with usage of (4.7) and (4.5)):

\[
(Lp_n)[z] - (abcdq^n - q^{-n})(z + z^{-1} - 2B_n) p_n[z] = (1 - abq^{n-1})(1 - acq^{n-1}) \times (1 - adq^{n-1})(1 - bcq^{n-1})(1 - bdq^{n-1})(1 - cdq^{n-1}) \cdot \frac{(1 + q)(1 - q^n)p_{n-1}[z]}{q^n(1 - abcdq^{2n-2})}, \tag{4.12}
\]

\[
(Lp_n)[z] + (abcdq^{n-1} - q^{-n})(z + z^{-1} - 2B_n) p_n[z] = -\frac{(1 + q)(1 - abcdq^{n-1})}{q^n(1 - abcdq^{2n})} p_{n+1}[z]. \tag{4.13}
\]

Lowering and raising relations for Askey-Wilson polynomials were earlier obtained by Bangerezako [5] (41). He obtained his lowering and raising operator by the factorization method, see Proposition 1 in [5]. His lowering and raising relation can be obtained from (4.12) and (4.13), respectively, by adding \( \frac{1}{2}(1 - q^{-1})(z - qz^{-1})(Dp_n)[z] \) to the left-hand sides of these relations (cf. Remark 2.4).
Remark 4.1. It turns out that the operator (4.7), which occurs in the structure relation for Askey-Wilson polynomials, is the trigonometric case \( p = 0 \) of the difference operator \( \Delta(a, b, c, d) \) with elliptic coefficients given by Rosengren [20, §6] (also replace \( q \) by \( q^2 \) in Rosengren’s operator in order to arrive at (4.7)). Rosengren observes, following Rains [19], that the operators \( \Delta(a, b, c, d) \) with \( abcd = q^{-N} \) \( (N = 0, 1, 2, \ldots) \) generate a representation of the Sklyanin algebra as in Sklyanin [21, Theorem 4]. Indeed, if we write \( L = L_{a,b,c,d} \) for the operator in (4.7) then

\[
L_{a,b,c,d} L_{q^a,q^b,q^{-1}c,q^{-1}d} = L_{a,b,c,d} L_{q^a,q^b,q^{-1}c,q^{-1}d}.
\]

This quasi-commutation relation, which can be proved in a straightforward way, is a specialization \( (p = 0, n = 1) \) of Rains’ relation [19, (3.27)] and it is a way to implement the relations in the Sklyanin algebra.

5 Continuous \( q \)-Jacobi polynomials

Continuous \( q \)-Jacobi polynomials

\[
P_n(z) = P_n^{(\alpha, \beta)} \left( \frac{1}{2}(z + z^{-1}) \mid q \right)
\]

(see [9, §7.5], [14, §3.10]) can be obtained as restrictions of Askey-Wilson polynomials in two different ways (see [14, §4.10]):

\[
P^{(\alpha, \beta)}_n(x \mid q) = \frac{q^{\left(\frac{n}{2}+\frac{1}{2}\right)n} p_n(x; q^{\frac{-\alpha}{2}+\frac{1}{4}}, -q^{\frac{\beta}{2}+\frac{1}{4}}, q^{\frac{1}{4}}, -q^{\frac{1}{4}} \mid q^{\frac{1}{2}})}{(-q^{\frac{n}{2}(\alpha+\beta+1)}; q^2)_n (q; q)_n}
= \frac{q^{\left(\frac{n}{2}+\frac{1}{4}\right)n} p_n(x; q^{\frac{-\alpha}{2}+\frac{1}{4}}, q^{\frac{1}{4}}, -q^{\frac{1}{2}+\frac{1}{4}}, -q^{\frac{1}{2}+\frac{1}{4}} \mid q)}{(-q^{\frac{n}{2}(\alpha+\beta+1)}; q^2)_2n (q; q)_n}.
\]

(5.2)

These polynomials are orthogonal with respect to the inner product

\[
\langle f, g \rangle := \oint f(z) g(z) \frac{(z^2, z^{-2}; q)_\infty}{(q^{\frac{2a+1}{4}} z, q^{\frac{2a+1}{4}} z^{-1}, q^{\frac{2b+1}{4}} z, -q^{\frac{2b+1}{4}} z^{-1}, q^2)_\infty} \frac{dz}{z}.
\]

(5.3)

The coefficients \( A_n \) and \( C_n \) in (2.3) here become:

\[
A_n = \frac{(1 - q^{n+1})(1 - q^{n+\alpha+\beta+1})}{2q^{\frac{n}{2}+\frac{1}{4}} (1 - q^{n+\frac{1}{2}(\alpha+\beta+1)})(1 - q^{n+\frac{1}{2}(\alpha+\beta+2)})}, \quad (5.4)
\]

\[
C_n = \frac{q^{\frac{n}{2}+\frac{1}{4}} (1 - q^{n+\alpha})(1 - q^{n+\beta})}{2(1 - q^{n+\frac{1}{2}(\alpha+\beta)})(1 - q^{n+\frac{1}{2}(\alpha+\beta+1)})}.
\]

(5.5)

Corresponding to (5.1), (5.2) we can obtain two versions of the operators \( L \) and \( D \) for continuous \( q \)-Jacobi polynomials by specialization of (4.7) and
As in (2.7), (2.8), or more generally in Remark 2.4, lowering and raising q-continuous structure relations above. This can be most easily seen in a formal way by (5.1) and (5.2). In particular, corresponding to (5.1) we obtain:

\[
(\tilde{L}f)[z] = \frac{\tilde{v}(z)f[qz] - \tilde{v}(z^{-1})f[q^{-1}z]}{z - z^{-1}},
\]

\[
\tilde{v}(z) = (1 - q^{\frac{1}{2}\alpha + \frac{3}{4}z})(1 + q^{\frac{1}{2}\beta + \frac{1}{4}z})(1 + q^{\frac{1}{2}\beta + \frac{1}{4}z}) z^{-2}.
\]  

(5.7)

Related to these operators are coefficients \(\gamma_n\) respectively \(\tilde{\gamma}_n\) (see (2.5)):

\[
\gamma_n = 2(q^{\frac{1}{4}(n+\alpha+\beta+2)} - q^{-\frac{1}{4}n}), \quad \tilde{\gamma}_n = 2(q^{n+\alpha+\beta+2} - q^{-n}).
\]  

(5.8)

The form (1.8) of the operator \(L\) can also be specialized corresponding to (5.1) and (5.2). In particular, corresponding to (5.1) we obtain:

\[
(Lf)[z] = \frac{1}{z} (1 - q) \left( q^{\frac{1}{2}\alpha + \frac{1}{4}z}, q^{\frac{1}{2}\alpha + \frac{1}{4}z}/z, -q^{\frac{1}{2}\beta + \frac{1}{4}z}, -q^{\frac{1}{2}\beta + \frac{1}{4}z}/z; q \right) \frac{\delta_q f(z)}{\delta_q x} \left( q^{\frac{1}{2}z_2}, q^{\frac{1}{2}z_2}/z; q \right) f(z).
\]  

(5.9)

By (2.6) and the formulas above we get two structure relations for continuous q-Jacobi polynomials:

\[
\frac{v(z)P_n[q^{\frac{1}{4}}z] - v(z^{-1})P_n[q^{-\frac{1}{4}}z]}{z - z^{-1}} = \gamma_n A_n P_{n+1}[z] - \gamma_{n-1} C_n P_{n-1}[z].
\]  

(5.10)

\[
\frac{\tilde{v}(z)P_n[qz] - \tilde{v}(z^{-1})P_n[q^{-1}z]}{z - z^{-1}} = \tilde{\gamma}_n A_n P_{n+1}[z] - \tilde{\gamma}_{n-1} C_n P_{n-1}[z].
\]  

(5.11)

As in (2.7), (2.8), or more generally in Remark 2.4, lowering and raising relations can also be written explicitly here (I will skip this).

Ismail [12, Theorem 15.5.2] gives an explicit lowering relation for continuous q-Jacobi polynomials which is proved by using a determinant formula due to Christoffel. This expresses orthogonal polynomials with respect to an orthogonality measure \(\Phi(x)d\mu(x)\) in terms of polynomials with orthogonality measure \(d\mu(x) (\Phi(x) a\) nonnegative polynomial on \(\text{supp}(\mu)\)), see [12, Theorem 2.7.1].

The structure relation (3.5) for Jacobi polynomials is a limit case of both structure relations above. This can be most easily seen in a formal way by
using the expressions for $L$ and $\tilde{L}$ involving the divided $q$-difference. Let us give the details for $L$ as given by (5.9). Rewrite (5.10) as

$$
\frac{2}{1-q}(L_q P_n)[z; q] = \frac{2}{1-q} \gamma_n(q) A_n(q) P_{n+1}[z; q] - \frac{2}{1-q} \gamma_{n-1}(q) C_n P_{n-1}[z; q],
$$

(5.12)

emphasizing the $q$-dependence. As $q \uparrow 1$, $P_n[z; q] \to P_n[z] = P_n^{(\alpha, \beta)}(\frac{z+q^{-1}}{2})$ (see [14, (5.10.1)]). Also, $A_n(q)$, $C_n(q)$ and $\frac{2}{1-q} \gamma_n(q)$ tend to $A_n$, $C_n$ and $4\gamma_n$ for Jacobi polynomials as given in [13]. Thus the right-hand side of (5.12) tends to the right-hand side of (2.6) for Jacobi polynomials, i.e., to the right-hand side of (3.5). Now consider the left-hand side of (5.12) with (6.1) substituted. Use that

$$
\lim_{q \uparrow 1} \left( \frac{q^n z; q}{z; q} \right)_\infty = (1 - z)^{-\alpha}
$$

(see [9] (1.3.19)). Hence

$$
\frac{(q^{\alpha} z^{\frac{1}{2}}, z^{\frac{1}{2}}, z^{\frac{1}{2}}, -q^2 z^{\frac{1}{2}}, q)}{(q^2 z, q^2 z, -q^2 z, -q^2 z, q)} \to (2 - z - \frac{1}{z})^{\frac{1}{2} - \frac{1}{\alpha}} (2 + z + \frac{1}{z})^{\frac{1}{2} - \frac{1}{\beta}},
$$

$$
\frac{(q^{\alpha} z, q^2 z, -q^2 z, -q^2 z, q)}{(q^{\alpha} z, q^{\alpha} z, z^{\frac{1}{2}}, -q^2 z, q)} \to (2 - z - \frac{1}{z})^{\frac{1}{2} + \frac{1}{\alpha}} (2 + z + \frac{1}{z})^{\frac{1}{2} + \frac{1}{\beta}}.
$$

Hence $\frac{2}{1-q}(L_q P_n)[z; q] \to 4(LP_n)[z]$ with $L$ given by (1.10). So (5.12) tends to 4 times (3.5) as $q \uparrow 1$.

6 Continuous $q$-ultraspherical polynomials

In view of [9] (7.5.34) and (5.1) continuous $q$-ultraspherical polynomials are specializations of Askey-Wilson polynomials as follows:

$$
C_n[z] = C_n(\frac{t}{z} (z + z^{-1}); t | q)
$$

$$
= \frac{(t; q^\frac{1}{2})_n}{(q^\frac{1}{2} t; q)_n (q; q)_n} p_n(\frac{t}{2} (z + z^{-1}); t^{\frac{1}{2}}, -t^{\frac{1}{2}}, q^{\frac{1}{2}}, -q^{\frac{1}{2}} | q^{\frac{1}{2}}).
$$

(6.1)

By specialization of (4.7) and (4.8) we obtain the two ways of writing the operator $L$ corresponding to (6.1):

$$
(L f)[z] = \frac{(1 - tz^2)(z^{-2} - q^2)}{z - z^{-1}} f[\frac{1}{2} z] - \frac{(1 - tz^{-2})(z^2 - q^2)}{z - z^{-1}} f[\frac{1}{2} z] - \frac{1}{2} (1 - q) \frac{(t z^2, t z^{-2}; q^2)_\infty}{(q^{\frac{1}{2}} z^2, q^{\frac{1}{2}} z^{-2}; q^2)_\infty} \delta_q \left( \frac{(q^{\frac{1}{2}} z^2, q^{\frac{1}{2}} z^{-2}; q^2)_\infty}{(q t z^2, q t z^{-2}; q^2)_\infty} f[z] \right).
$$

(6.2)

(6.3)
Then the structure relation (4.11) for Askey-Wilson polynomials specializes to the following structure relation for the polynomials $C_n$:

\[
\frac{(1-tz^2)(z^2-q^{\frac{1}{2}})}{z-z^{-1}} C_n[q^{\frac{1}{2}} z] - \frac{(1-tz^{-2})(z^2-q^{\frac{1}{2}})}{z-z^{-1}} C_n[q^{-\frac{1}{2}} z] = - \frac{(1-tq^{n+\frac{1}{2}})(1-q^{n+1})}{q^{\frac{1}{2}n}(1-tq^n)} C_n[z] + \frac{(1-tq^{n-\frac{1}{2}})(1-t^2q^{n-1})}{q^{\frac{1}{2}n-\frac{1}{2}}(1-tq^n)} C_{n-1}[z].
\] (6.4)

In [15, §2] some lowering and raising relations for continuous $q$-ultraspherical polynomials were given which were obtained as $A_1$ cases of the lowering and raising relations for the $A_n$ Macdonald polynomials in [13]. For instance:

\[- \frac{t-z^{-2}}{z-z^{-1}} C_n[q^{\frac{1}{2}} z] + \frac{t-z^2}{z-z^{-1}} C_n[q^{-\frac{1}{2}} z] + q^{-\frac{1}{2}n}(z+z^{-1}) C_n[z] = (q^{-\frac{1}{2}n} - t^2q^{\frac{1}{2}n-1}) C_{n-1}[z], \tag{6.5}\]

\[- \frac{t^2z^2-1}{z-z^{-1}} C_n[q^{\frac{1}{2}} z] + \frac{t^2z^2-1}{z-z^{-1}} C_n[q^{-\frac{1}{2}} z] + q^{-\frac{1}{2}n}(z+z^{-1}) C_n[z] = (q^{-\frac{1}{2}n} - q^{\frac{1}{2}n+1}) C_{n+1}[z]. \tag{6.6}\]

By subtracting (6.5) from (6.6) we obtain another structure relation for continuous $q$-ultraspherical polynomials of the form (1.6), but with an operator $L$ which is not skew symmetric:

\[z^{-1}(1-tz^2)C_n[q^{\frac{1}{2}} z] + z(1-tz^{-2})C_n[q^{-\frac{1}{2}} z] = q^{-\frac{1}{2}n}(1-q^{n+1})C_{n+1}[z] - q^{-\frac{1}{2}n}(1-t^2q^{n-1})C_{n-1}[z]. \tag{6.7}\]

Relation (6.7) is connected with relation (6.4) by yet another relation of the form (1.6):

\[- \frac{(1-tz^2)((1+z^{-2})}{z-z^{-1}} C_n[q^{\frac{1}{2}} z] + \frac{(1-tz^{-2})(1+z^2)}{z-z^{-1}} C_n[q^{-\frac{1}{2}} z] = \frac{(q^{-\frac{1}{2}n} + tq^{\frac{1}{2}n})(1-q^{n+1})}{1-tq^n} C_{n+1}[z] + \frac{(q^{-\frac{1}{2}n} + tq^{\frac{1}{2}n})(1-t^2q^{n-1})}{1-tq^n} C_{n-1}[z]. \tag{6.8}\]

Indeed, (6.4) equals $\frac{1}{2}(q-1)$ times (6.8) plus $\frac{1}{2}(q+1)$ times (6.7). Relation (6.8) is a consequence of the three-term recurrence relation

\[(z+z^{-1})C_n[z] = \frac{1-q^{n+1}}{1-tq^n} C_{n+1}[z] + \frac{1-t^2q^{n-1}}{1-tq^n} C_{n-1}[z]. \tag{6.9}\]
and the second order \( q \)-difference formula

\[
\frac{1 - tz^2}{1 - z^2} C_n[q^\frac{1}{2} z] + \frac{1 - tz^{-2}}{1 - z^{-2}} C_n[q^{-\frac{1}{2}} z] = (q^{-\frac{1}{2} n} + q^\frac{1}{2} n t) C_n[z], \tag{6.10}
\]

which last formula is the specialization by (6.1) of the second order \( q \)-difference formula (4.6) for Askey-Wilson polynomials.

## 7 Big \( q \)-Jacobi polynomials

Big \( q \)-Jacobi polynomials (see [9, §7.3], [14, §3.5]) are given by

\[
P_n(x) = P_n(x; a, b, -c; q) := \genfrac{[}{]}{0pt}{}{q^{-n}, abq^{-1}}{aq, -cq} P_n(\frac{1}{2}(a^{-1}x + ax^{-1}); \varepsilon, \varepsilon^{-1} aq, -\varepsilon^{-1} cq, -\varepsilon bc^{-1} | q) \tag{7.1}
\]

They can be obtained as limits of Askey-Wilson polynomials (see [14, (4.1.3)]):

\[
\lim_{\varepsilon \to 0} (aq, -cq, -\varepsilon^2 bc^{-1}; q)_n P_n(\frac{1}{2}(a^{-1}x + ax^{-1}); \varepsilon, \varepsilon^{-1} aq, -\varepsilon^{-1} cq, -\varepsilon bc^{-1} | q) = P_n(x; a, b, -c; q). \tag{7.2}
\]

Make in (4.11) together with (1.8) the substitutions corresponding to the left-hand side of (7.2) and let \( \varepsilon \to 0 \). Then we obtain a structure relation for big \( q \)-Jacobi polynomials:

\[
(LP_n)(x) = \frac{(1 - aq^{-n+1})(1 + cq^{n+1})(1 - abq^{n+1})}{q^{n+2}ac(1 - abq^{2n+1})} P_{n+1}(x)
- \frac{(1 - q^n)(1 - bq^{n})(1 + abc^{-1}q^n)}{1 - abq^{2n+1}} P_{n-1}(x), \tag{7.3}
\]

where

\[
(Lf)(x) := \frac{(1 - x)(1 + bc^{-1}x) f(qx) - (1 - a^{-1}q^{-1}x)(1 + c^{-1}q^{-1}x) f(q^{-1}x)}{x}, \tag{7.4}
\]

Note that we can rewrite (7.4) as

\[
(Lf)(x) = (q - q^{-1}) \frac{(x, -bc^{-1}x; q^2)_\infty}{(qa^{-1}x, -qc^{-1}x; q^2)_\infty} d_{q,x} \left( \frac{(a^{-1}x, -c^{-1}x; q^2)_\infty}{(qx, -qbc^{-1}x; q^2)_\infty} f[x] \right), \tag{7.5}
\]

where \( d_{q,x} \) is a central \( q \)-derivative:

\[
d_{q,x}(g(x)) := \frac{g(qx) - g(q^{-1}x)}{(q - q^{-1}) x}. \tag{7.6}
\]
We can rewrite (7.3) in two steps as the explicit structure relation of the form
\[(x - 1)(bx + c)D_{q,x}(P_n(x)) = \tilde{a}_nP_{n+1}(x) + \tilde{b}_nP_n(x) + \tilde{c}_nP_{n-1}(x)\]  
(7.7)
given in [18], where the \(q\)-derivative \(D_q\) is defined by (1.5). First eliminate \(P_n(q^{-1}x)\) from (7.3) by means of the second order \(q\)-difference equation for big \(q\)-Jacobi polynomials. Then we obtain from (7.3) a relation of the form
\[(x - 1)(bx + c)D_{q,x}(P_n(x)) = \alpha_nP_{n+1}(x) + (\delta_nx + \beta_n)P_n(x) + \gamma_nP_{n-1}(x).\]  
(7.8)
Next eliminate \(xP_n(x)\) from (7.8) by means of the three-term recurrence relation in order to obtain a relation of the form (7.7).
