(March 31, 2022)

For pseudoscalar meson electroproduction off the nucleon in parallel kinematics a relation between three polarization observables is derived. It is shown that, without Rosenbluth separation, a measurement of the longitudinal strength can be achieved through three different ways. They are discussed with preliminary MAMI data for the \( p(e, e'p)\pi^0 \) reaction in the energy range of the \( \Delta(1232) \) resonance.

Keywords: delta resonance, quadrupole excitation, recoil polarization

I. INTRODUCTION

In the past few years, elastic and quasielastic scattering experiments yielded decisive results concerning the electromagnetic structure of proton [1] and neutron [2] by taking advantage of double polarization observables. These provide also high sensitivity to the longitudinal electromagnetic coupling of nucleon resonances [3]. Experimentally, these short lived resonances can be tagged through their decay into the nucleon-meson channel. Pseudoscalar meson production is thus of particular interest for resonance physics. Due to the inherent problem of separation of non-resonant background, unpolarized measurements are invaluable complemented by polarization experiments, which also profit from their insensitivity to major sources of systematic uncertainties.

Furthermore, polarization observables can be utilized for a separation of longitudinal and transverse response. Thus, the experimental difficulties of the standard Rosenbluth-technique [2,3] can be circumvented. Three different methods for the extraction of the ratio of longitudinal and transverse strength are discussed on the basis of first, preliminary \( p(e, e'p)\pi^0 \) data in the energy range of the \( \Delta(1232) \) resonance [4,5] from the Mainz Microtron MAMI.

II. RECOIL POLARIZATION IN PARALLEL KINEMATICS

The present double-polarization experiments focus on the situation of parallel kinematics, where the recoiling nucleon of the \( p(e, e'p)\pi^0 \) reaction is detected along the direction of the momentum transfer, \( \vec{q} \). In this case the components of the recoil nucleon polarization \(^1\) are given by:

\[
P_x = P_c \cdot c_2 \cdot \frac{R_{LT}}{R_T + \epsilon_L R_L} \quad (1)
\]
\[
P_y = c_+ \cdot \frac{R_{LT}}{R_T + \epsilon_L R_L} \quad (2)
\]
\[
P_z = P_c \cdot c_0 \cdot \frac{R_{LT}}{R_T + \epsilon_L R_L} \quad (3)
\]

The coordinate frame is defined relative to the electron scattering plane as depicted in Fig.1. In contrast to ref. [1] here we use the notation of Drechsel and Tiator [2]. The structure functions, \( R_{LT} \), have to be taken at the pion cm-angle of \( \Theta_{cm} = 180^\circ \). \( P_c \) denotes the longitudinal electron polarization, and the kinematical factors are

\[
c_\pm = \sqrt{2\epsilon L (1 \pm \epsilon)} \quad \text{and} \quad c_0 = \sqrt{1 - \epsilon^2}, \quad (4)
\]

where \( \epsilon = (1 + 2q^2/Q^2 \tan^2 \frac{1}{2} \vartheta_e)^{-1} \) and \( \epsilon_L = (Q^2/\omega_{cm}^2) \epsilon \) represent the degrees of transverse and longitudinal polarization of the virtual photon, respectively. \( Q^2 \) is the negative squared four-momentum transfer, \( \vartheta_e \) the electron scattering angle and \( \omega_{cm} \) the energy transfer in the photon-nucleon cm frame.

From the components of recoil polarization (Eqs.3) we define reduced polarizations through normalization by the virtual photon polarization factors:

\[
\chi_x = \frac{1}{P_c c_2} \cdot P_x = \frac{R_{LT}}{R_T + \epsilon_L R_L} \quad (5)
\]
\[
\chi_y = \frac{1}{c_+} \cdot P_y = \frac{R_{LT}}{R_T + \epsilon_L R_L} \quad (6)
\]
\[
\chi_z = \frac{1}{P_c c_0} \cdot P_z = \frac{R_{LT}}{R_T + \epsilon_L R_L} \quad (7)
\]

The structure functions are conveniently expressed in terms of six helicity amplitudes, \( H_{1-6} \), or CGLN amplitudes, \( F_{1-6} \) [2,5]. This yields:

\[
R_T = \frac{1}{2} |H_4|^2 = |F_1 + F_2|^2 \quad (8)
\]

\(^1\)Target polarization is equivalent to the measurement of recoil polarization when the cross-section asymmetry with regard to the reversal of beam helicity is considered.
\[ R_L = |H_0|^2 = |F_5 - F_6|^2 \] (9)

\[ R_{LT'}^t = -\frac{1}{\sqrt{2}} \text{Re}(H_0^* H_4) \]
\[ = -\text{Re}\{(F_6^* - F_5^*)(F_1 + F_2)\} \] (10)

\[ R_{LT}^n = \frac{1}{\sqrt{2}} 3m\{H_0^* H_4\} \]
\[ = 3m((F_6^* - F_5^*)(F_1 + F_2)) \] (11)

\[ R_{TT'}^T = \frac{1}{2}|H_4|^2 = |F_1 + F_2|^2 \] (12)

\( R_{LT'}^t \) and \( R_{LT}^n \) represent real and imaginary parts of the same complex interference term. The equality

\[ R_T = R_{TT'}^T \] (13)

is a peculiarity of parallel kinematics.

\[ e' \]
\[ \pi^0 \]
\[ e \]
\[ \pi \]
\[ \mathbf{P}_e \]
\[ \mathbf{P}_x \]
\[ \mathbf{P}_y \]
\[ \mathbf{P}_z \]

FIG. 1. Electroproduction of pseudoscalar mesons in parallel kinematics for the example of the \( p(e', e'p)\pi^0 \) reaction. The components \( P_{x,y,z} \) of the proton polarization are defined relative to the electron scattering plane.

### III. POLARIZATION RELATION AND L/T SEPARATION

From Eqs. (12) it can be easily seen that

\[ \chi_x^2 + \chi_y^2 = \frac{1}{2}|H_4|^2 |H_0|^2 \frac{R_T \cdot R_L}{(R_T + \epsilon_L R_L)^2} \] (14)

and

\[ \chi_z^2 = \frac{R_T^2}{(R_T + \epsilon_L R_L)^2}. \] (15)

Therefore, the ratio between longitudinal and transverse response is given by

\[ \frac{R_L}{R_T} = \frac{\chi_x^2 + \chi_y^2}{\chi_z^2}. \] (16)

The extraction of \( R_L/R_T \) from Eq. (14) requires the measurement of all three polarization components. It can also be obtained from \( \chi_z \) alone [15] by rewriting Eq. (15):

\[ \frac{R_L}{R_T} = \frac{1}{\epsilon_L} \left( \frac{1}{\chi_z} - 1 \right) \] (17)

Combining Eqs. (17) and (16) we directly receive a model independent relation between the three reduced polarizations:

\[ \chi_x^2 + \chi_y^2 = \frac{1}{\epsilon_L} \chi_z (1 - \chi_z) \] (18)

This equation relates the absolute value of the transverse polarization with the longitudinal polarization. It represents a constraint for any model. For example, it is perfectly fulfilled by the Mainz Unitary Isobar Model [10] for pion photo and electroproduction.

The relation can also serve as a consistency check for experimental data. Up to now there is one preliminary data set available with all three components of proton polarization simultaneously measured in the reaction \( p(e', e'p)\pi^0 \) at the energy of the \( \Delta \) resonance [10,11]. Within their present errors these data fulfill Eq. (18):

\[ \chi_x^2 + \chi_y^2 = 0.0348 \pm 0.0045_{\text{stat}} \pm 0.0031_{\text{syst}} = \frac{1}{\epsilon_L} \chi_z (1 - \chi_z) = 0.0519 \pm 0.022_{\text{stat}} \pm 0.007_{\text{syst}} \] (19)

We note, however, that the rhs of Eq. (19) does not produce a very strong constraint. This is due to the unfavorable error propagation when the small deviation of \( \chi_z \) from unity is measured.

The determination of \( R_L/R_T \) from Eq. (17) suffers by the same reason. We obtain:

\[ \frac{R_L}{R_T} = 0.066^{+0.038}_{-0.034_{\text{stat}}} \pm 0.011_{\text{syst}} \] (20)

A relative statistical error of 6.2% in \( \chi_z \) is amplified to 57.6% in \( R_L/R_T \). This is a consequence of the weak influence of \( R_L \) on the longitudinal polarization component. Therefore, in the \( \Delta(1232) \) region \( P_z \) should rather be used as an experimental consistency check, because it is almost entirely determined by the polarization of the electron beam and electron kinematics [23]:

\[ P_z \approx P_e \cdot c_0 \] (21)

A better way to determine the longitudinal strength is through Eq. (16) which yields

\[ \frac{R_L}{R_T} = 0.044 \pm 0.006_{\text{stat}} \pm 0.004_{\text{syst}}. \] (22)

However, all three polarization components need to be measured simultaneously. A procedure which requires only the two transverse reduced polarizations starts from Eq. (14) as a quadratic equation for \( R_L/R_T \). The solutions are

\[ \frac{R_L}{R_T} = \left[ \alpha_L \pm \sqrt{\alpha_L^2 - \epsilon_L^2} \right]^{-1}, \] (23)

where
\[ \alpha_L = \frac{1}{2(\chi^2_x + \chi^2_y)} - \epsilon_L. \]  

(24)

To the extent that \( \frac{R_L}{R_T} \ll \frac{1}{\epsilon_L} \), Eq.23 can be simplified to

\[ \frac{R_L}{R_T} = \frac{1}{2\alpha_L}. \]  

(25)

The second solution yields \( R_L > R_T \) and is thus obviously unphysical. With Eq.25 the preliminary MAMI data yield the result

\[ \frac{R_L}{R_T} = 0.040 \pm 0.006_{\text{stat}} \pm 0.004_{\text{syst}}. \]  

(26)

For the latter two approaches it is possible to practically maintain the experimental errors of the reduced polarizations in the extracted ratio. In contrast to the extraction through Eq.17 there is no error amplification, but the measurement of two or three polarization components is required. Experimentally, the false systematic asymmetries of the recoil polarimeter need to be under control. While they can be eliminated in the electron-helicity dependent components \( P_x \) and \( P_z \), they influence the extraction of \( P_y \).

IV. SUMMARY AND CONCLUSIONS

For the case of electroproduction of pseudoscalar mesons off the nucleon in parallel kinematics with longitudinally polarized beam and with either measurement of recoil nucleon polarization or target polarization a set of three reduced polarizations has been defined. There exists a model independent relation between the quadratic sum of the two transverse reduced polarizations and the longitudinal one. It puts a constraint on both phenomenological models and experimental data.

The polarization observables offer the possibility to measure the ratio of longitudinal to transverse strength without the need of a Rosenbluth-separation. Three different ways have been discussed which require the measurement of one, two or three of the reduced polarizations. While the \( L/T \)-ratio from \( \chi_z \) alone suffers from a very unfavourable error propagation, in particular the quadratic sum \( \chi^2_x + \chi^2_y \) is well suited for a measurement of the longitudinal response.
