ON THE UNIFORM COMPUTATIONAL CONTENT
OF THE BAIRE CATEGORY THEOREM

VASCO BRATTKA, MATTHEW HENDTLASS, AND ALEXANDER P. KREUZER

Abstract. We study the uniform computational content of different versions of the Baire Category Theorem in the Weihrauch lattice. The Baire Category Theorem can be seen as a pigeonhole principle that states that a complete (i.e., “large”) metric space cannot be decomposed into countably many nowhere dense (i.e., “small”) pieces. The Baire Category Theorem is an illuminating example of a theorem that can be used to demonstrate that one classical theorem can have several different computational interpretations. For one, we distinguish two different logical versions of the theorem, where one can be seen as the contrapositive form of the other one. The first version aims to find an uncovered point in the space, given a sequence of nowhere dense closed sets. The second version aims to find the index of a closed set that is somewhere dense, given a sequence of closed sets that cover the space. Even though the two statements behind these versions are equivalent to each other in classical logic, they are not equivalent in intuitionistic logic and likewise they exhibit different computational behavior in the Weihrauch lattice. Besides this logical distinction, we also consider different ways how the sequence of closed sets is “given”. Essentially, we can distinguish between positive and negative information on closed sets. We discuss all the four resulting versions of the Baire Category Theorem. Somewhat surprisingly it turns out that the difference in providing the input information can also be expressed with the jump operation. Finally, we also relate the Baire Category Theorem to notions of genericity and computably comeager sets.

Keywords: Computable analysis, Weihrauch lattice, Baire category, genericity, reverse mathematics.

1. Introduction

The classical Baire Category Theorem is an important tool that is used to prove many other theorems in mathematics. It can be seen as a Pigeonhole Principle that states that a complete (i.e., “large”) metric space cannot be decomposed in countably many nowhere dense (i.e., “small”) pieces.

**Theorem 1.1** (Baire Category Theorem). A complete metric space $X$ cannot be obtained as a countable union $X = \bigcup_{i=0}^{\infty} A_i$ of nowhere dense closed sets $A_i \subseteq X$.

We recall that a set $A \subseteq X$ is called **nowhere dense** if its interior $A^\circ$ is empty. Otherwise it is called **somewhere dense**. Obviously, a closed set is nowhere dense if and only if its complement is a dense open set. In a slightly stronger version expressed for open sets the theorem reads as follows.

**Theorem 1.2** (Baire Category Theorem). Let $X$ be a complete metric space. If $(U_n)_n$ is a sequence of dense open subsets $U_n \subseteq X$, then $\bigcap_{i=0}^{\infty} U_i$ is also dense in $X$.

We recall that a set is called **meager** if it can be written as a countable union of nowhere dense sets and it is called **comeager** if it is the complement of a meager set (i.e., if it contains a countable intersection of dense open sets).

There are two natural logical ways of writing the Baire Category Theorem [1] as a for-all-exists statement: one which claims the existence of a point $x \in X$, the other one which claims the existence of a natural number index $i \in \mathbb{N} := \{0, 1, 2, \ldots\}$.

- (X) For every sequence $(A_i)_{i \in \mathbb{N}}$ of nowhere dense closed sets $A_i \subseteq X$ there exists a point $x \in X \setminus \bigcup_{i=0}^{\infty} A_i$.
- (N) For every sequence $(A_i)_{i \in \mathbb{N}}$ of closed sets $A_i \subseteq X$ such that $X = \bigcup_{i=0}^{\infty} A_i$, there exists an index $i \in \mathbb{N}$ such that $A_i$ is somewhere dense.

Secondly, we can represent the closed sets $A \subseteq X$ either with the negative information representation $\psi_-$ or the positive information representation $\psi_+$. We denote the corresponding hyperspaces of closed subsets by $A_-(X)$ and $A_+(X)$, respectively (see Section [3] for more details). This yields four different versions of the Baire Category Theorem that are summarized in the following table:

| $X$ | $\mathbb{N}$ |
|-----|--------------|
| $-$ | $\text{BCT}_0$ | $\text{BCT}_1$ |
| $+$ | $\text{BCT}_2$ | $\text{BCT}_3$ |

We call $\text{BCT}_1$ and $\text{BCT}_3$ the **discrete** versions of the Baire Category Theorem, since the output is an index. We now give precise definitions of these operations (the notations used will be explained in the next section).

**Definition 1.3** (Baire Category Theorem). Let $X$ be a computable Polish space. We introduce the following operations:

1. $\text{BCT}_{0,X} : \subseteq A_-(X)^\mathbb{N} \Rightarrow X$, $\text{BCT}_{2,X} : \subseteq A_+(X)^\mathbb{N} \Rightarrow X$ with
   - $\text{BCT}_{0,X}(A_i) := \text{BCT}_{2,X}(A_i) := X \setminus \bigcup_{i=0}^{\infty} A_i$,
   - $\text{dom}(\text{BCT}_{0,X}) := \text{dom}(\text{BCT}_{2,X}) := \{(A_i) : (\forall i) A_i^\circ = \emptyset\}$.

2. $\text{BCT}_{1,X} : \subseteq A_-(X)^\mathbb{N} \Rightarrow \mathbb{N}$, $\text{BCT}_{3,X} : \subseteq A_+(X)^\mathbb{N} \Rightarrow \mathbb{N}$ with
   - $\text{BCT}_{1,X}(A_i) := \text{BCT}_{3,X}(A_i) := \{i \in \mathbb{N} : A_i^\circ \neq \emptyset\}$ and
   - $\text{dom}(\text{BCT}_{1,X}) := \text{dom}(\text{BCT}_{3,X}) := \{(A_i) : X = \bigcup_{i=0}^{\infty} A_i\}$.

We should mention that the exact location of these operations in the Weihrauch lattice does depend on the underlying space $X$. For ease of notation we will typically...
omit the space $X$ in the notation of $\text{BCT}_i$, but we often explicitly mention the space that we are using.

We offer the following interpretations of the four forms of Baire’s Category Theorem.

- $\text{BCT}_0$ can be seen as the constructive Baire Category Theorem, which can be used to construct all sorts of computable (counter)examples [5, 7].
- $\text{BCT}_1$ can be seen as the functional analytic Baire Category Theorem, whose computational content is equivalent to that of many basic theorems of functional analysis, such as the Banach Inverse Mapping Theorem [10].
- $\text{BCT}_2$ is a computability theoretic version of the Baire Category Theorem, which is closely related to the notion of 1-genericity (see Section 9).
- $\text{BCT}_3$ is a combinatorial version of the Baire Category Theorem, which (for perfect spaces $X$) is computationally equivalent to the cluster point problem of the natural numbers, as we will show below in Theorem 4.3.

We mention that analogs of $\text{BCT}_0$ and $\text{BCT}_2$ have already been studied in reverse mathematics under the names B.C.T.I and B.C.T.II [17] (see also [33]). Another version of the Baire Category Theorem appeared in reverse mathematics under the name $\Pi^1_0 G$, which stands for $\Pi^1_0$-genericity [23, Page 5823]. In Section 8 we will show that $\Pi^1_0 G$ is equivalent to $\text{BCT}_2$.

Our goal in this paper is to study the uniform computational content of the Baire Category Theorem in the Weihrauch lattice. This study can be seen as a continuation of [14] and we refer the reader to this source for all undefined notions.

We briefly mention what is already known on the Baire Category Theorem in the Weihrauch lattice. In [5, Theorem 6] it has been proved that $\text{BCT}_0$ is computable and in [10, Theorem 5.2] it has been proved that for non-trivial spaces $\text{BCT}_1$ is equivalent to discrete choice $C_N$ and hence complete for the class of functions that are computable with finitely many mind changes [8, Theorem 7.11]. We summarize these results.

**Fact 1.4.** Let $X$ be a computable Polish space. Then $\text{BCT}_0$ is computable and $\text{BCT}_1 \equiv_{sW} C_N$ is computable with finitely many mind changes.

In fact, in [10, Theorem 5.2] only $C_N \leq_{W} \text{BCT}_1$ and $\text{BCT}_1 \leq_{sW} C_N$ was proved. But it is easy to see that also $C_N \leq_{sW} \text{BCT}_1$ holds.

In Section 2 we introduce some basic concepts related to the Weihrauch lattice. In Section 3 we discuss different representation of the hyperspace of closed subsets. In particular, we introduce the spaces $\mathcal{A}_-(X)$ and $\mathcal{A}_+(X)$ of closed subsets represented by negative and positive information respectively. We prove that the jump of $\mathcal{A}_-(X)$ can be described with the cluster point representation. This enables us to prove in Section 4 that (for perfect Polish spaces)

$$\text{BCT}_0' \equiv_{sW} \text{BCT}_2 \text{ and } \text{BCT}_1' \equiv_{sW} \text{BCT}_3.$$

In other words, the change of the input space from $\mathcal{A}_-(X)$ to $\mathcal{A}_+(X)$ can equivalently be expressed by an application of the jump. This is somewhat surprising and simplifies the picture, because we are essentially left with the versions $\text{BCT}_0$ and $\text{BCT}_1$ of the Baire Category Theorem up to jumps. In Section 5 we prove that $\text{BCT}_0$ and $\text{BCT}_2$ are parallelizable and in Section 6 we prove that for any two computable perfect Polish spaces $\text{BCT}_0$ yields the same strong equivalence class. This holds also for $\text{BCT}_2$ and the mentioned type of spaces include Cantor space and Baire space. In Section 7 we prove that the seemingly stronger version of the Baire Category Theorem expressed in Theorem 1.2 is not actually stronger in terms of its computational content. In Section 8 we prove

$$\Pi^1_0 G \equiv_{sW} \text{BCT}_2$$
and in Section [10] we study the problem of 1−genericity 1-GEN. Among other things we prove that 1-GEN lies between $\text{BCT}_0$ and $\text{BCT}_2$, i.e.,

$$\text{BCT}_0 \leq_{\text{aw}} 1\text{-GEN} \leq_{\text{aw}} \text{BCT}_2.$$  

We also prove that $\lim_j$ is an upper bound on $\text{BCT}_2$ ($\lim_j$ is the limit operation with respect to the jump topology). Additionally, we study effective versions of comeager sets related to $\text{BCT}_0$, $\text{BCT}_2$ and $\text{BCT}_0$. Finally, in Section [10] we discuss probabilistic aspects of the Baire Category Theorem. Among other things we prove a uniform version of the Theorem of Kurtz that states that

$$1\text{-GEN} \leq_{\text{aw}} (1-\ast)-\text{WWKL},$$  

i.e., 1-GEN is reducible to a certain variant of Weak Weak König’s Lemma. On the other hand, we prove that there is a co-c.e. comeager set (i.e., one of the effective type that corresponds to $\text{BCT}_2$) without points that are low for $\Omega$. Using this result we can separate 1-GEN and $\text{BCT}_2$.

2. Preliminaries

In this section we give a brief introduction into the Weihrauch lattice and we provide some basic notions from probability theory.

Pairing Functions. We are going to use some standard pairing functions in the following that we briefly summarize. As usual, we denote by $(n, k) := \frac{1}{2}(n + k + 1)(n + k) + k$ the Cantor pair of two natural numbers $n, k \in \mathbb{N}$ and by $(p, q)(n) := p(k)$ if $n = 2k$ and $(p, q)(n) = q(k)$, if $n = 2k + 1$, the pairing of two sequences $p, q \in \mathbb{N}^\mathbb{N}$.

By $(k, p)(n) := kp$ we denote the natural pairing of a number $k \in \mathbb{N}$ with a sequence $p \in \mathbb{N}^\mathbb{N}$. We also define a pairing function $(p_0, p_1) := ((p_0(0), p_1(0)), (j_0, j_1))$, for $p_0, p_1 \in \mathbb{N} \times 2^{\mathbb{N}}$, where $j_i(n) = p_i(n + 1)$. Finally, we use the pairing function $(p_0, p_1, p_2, \ldots)(i, j) := p_i(j)$ for $p_i \in \mathbb{N}^\mathbb{N}$.

The Weihrauch Lattice. The original definition of Weihrauch reducibility is due to Klaus Weihrauch and has been studied for many years [34, 36, 37, 21, 4, 6]. More recently it has been noticed that a certain variant of this reducibility yields a lattice that is very suitable for the classification of the computational content of mathematical theorems [20, 29, 30, 11, 10, 8, 13]. The basic reference for all notions from computable analysis is Weihrauch’s textbook [38]. The Weihrauch lattice is a lattice of multi-valued functions on represented spaces.

A representation $\delta$ of a set $X$ is just a surjective partial map $\delta \subseteq \mathbb{N}^\mathbb{N} \to X$. In this situation we call $(X, \delta)$ a represented space. In general we use the symbol “$\subseteq$” in order to indicate that a function is potentially partial. We work with partial multi-valued functions $f : \subseteq X \equiv Y$ where $f(x) \subseteq Y$ denotes the set of possible values upon input $x \in \text{dom}(f)$. If $f$ is single-valued, then for the sake of simplicity we identify $f(x)$ with its unique inhabitant. We denote the composition of two (multi-valued) functions $f : \subseteq X \equiv Y$ and $g : \subseteq Y \equiv Z$ either by $g \circ f$ or by $gf$. It is defined by

$$g \circ f(x) := \{z \in Z : (\exists y \in Y)(z \in g(y) \text{ and } y \in f(x))\},$$

where $\text{dom}(g \circ f) := \{x \in X : f(x) \subseteq \text{dom}(g)\}$. Using represented spaces we can define the concept of a realizer.

**Definition 2.1** (Realizer). Let $f : \subseteq (X, \delta_X) \equiv (Y, \delta_Y)$ be a multi-valued function on represented spaces. A function $F : \subseteq \mathbb{N}^\mathbb{N} \to \mathbb{N}^\mathbb{N}$ is called a realizer of $f$, in symbols $F \vdash f$, if $\delta_Y F(p) \in f(\delta_X(p))$ for all $p \in \text{dom}(f \delta_X)$.  

Realizers allow us to transfer the notions of computability and continuity and other notions available for Baire space to any represented space; a function between represented spaces will be called computable if it has a computable realizer, etc. Now we can define Weihrauch reducibility.

**Definition 2.2** (Weihrauch reducibility). Let \( f, g \) be multi-valued functions on represented spaces. Then \( f \) is said to be **Weihrauch reducible** to \( g \), in symbols \( f \leq_W g \), if there are computable functions \( K, H : \mathbb{N}^N \to \mathbb{N}^N \) such that \( H(\text{id}, GK) \vdash f \) for all \( G \vdash g \). Moreover, \( f \) is said to be **strongly Weihrauch reducible** to \( g \), in symbols \( f \leq_{SW} g \), if an analogous condition holds, but with the property \( HGK \vdash f \) in place of \( H(\text{id}, GK) \vdash f \).

The difference between ordinary and strong Weihrauch reducibility is that the "output modifier" \( H \) has direct access to the original input in case of ordinary Weihrauch reducibility, but not in case of strong Weihrauch reducibility. There are algebraic and other reasons to consider ordinary Weihrauch reducibility as the more natural variant. For instance, one can characterize the reduction \( f \leq_W g \) as follows: \( f \leq_W g \) holds if and only if a Turing machine can compute \( f \) in such a way that it evaluates the “oracle” \( g \) exactly on one (usually infinite) input during the course of its computation [35, Theorem 7.2]. We will use the strong variant \( \leq_{SW} \) of Weihrauch reducibility mostly for technical purposes; for instance it is better suited to study jumps (since jumps are monotone with respect to strong reductions but in general not for ordinary reductions).

We note that the relations \( \leq_W \), \( \leq_{SW} \) and \( \vdash \) implicitly refer to the underlying representations, which we will only mention explicitly if necessary. It is known that these relations only depend on the underlying equivalence classes of representations and not on the specific representatives (see Lemma 2.11 in [11]). The relations \( \leq_W \) and \( \leq_{SW} \) are reflexive and transitive, thus they induce corresponding partial orders on the sets of their equivalence classes (which we refer to as **Weihrauch degrees** and **strong Weihrauch degrees** respectively). These partial orders will be denoted by \( \leq_W \) and \( \leq_{SW} \) as well. The induced lattice and semi-lattice, respectively, are distributive (for details see [30] and [11]). We use \( \equiv_W \) and \( \equiv_{SW} \) to denote the respective equivalences regarding \( \leq_W \) and \( \leq_{SW} \), by \( \ll_W \) and \( \ll_{SW} \) we denote strict reducibility and by \( |W|, |SW| \) we denote incomparability in the respective sense.

**The Algebraic Structure.** The partially ordered structures induced by the two variants of Weihrauch reducibility are equipped with a number of useful algebraic operations that we summarize in the next definition. We use \( X \times Y \) to denote the ordinary set-theoretic product, \( X :\!\!: Y := (\{0\} \times X) \cup (\{1\} \times Y) \) to denote disjoint sums or coproducts, and by \( \bigsqcup_{n=0}^{\infty} X_i := \bigcup_{i=0}^{\infty} \{i\} \times X_i \) we denote the infinite coproduct. By \( X^i \) we denote the \( i \)-fold product of a set \( X \) with itself, where \( X^0 = \{()\} \) is some canonical singleton. By \( X^*: := \bigcup_{n=0}^{\infty} X^n \) we denote the set of all finite sequences over \( X \) and by \( X^N \) the set of all infinite sequences over \( X \). All these constructions have parallel canonical constructions on representations and the corresponding representations are denoted by \( [\delta_X, \delta_Y] \) for the product of \( (X, \delta_X) \) and \( (Y, \delta_Y) \), and by \( \delta_X^n \) for the \( n \)-fold product of \( (X, \delta_X) \) with itself, where \( n \in \mathbb{N} \) and \( \delta_X^0 \) is a representation of the one-point set \( \{()\} = \{\varepsilon\} \). By \( \delta_X \sqcup \delta_Y \) we denote the representation of the coproduct, by \( \delta_X^* \) the representation of \( X^* \) and by \( \delta_X^N \) the representation of \( X^N \). For instance, \( (\delta_X \sqcup \delta_Y) \) can be defined by \( (\delta_X \sqcup \delta_Y)(n, p) := (0, \delta_X(p)) \) if \( n = 0 \) and \( (\delta_X \sqcup \delta_Y)(n, p) := (1, \delta_Y(p)) \) otherwise. Likewise, \( \delta_X^n(p) := (n, \delta_X^p(p)) \). See [38] or [11] [30] [8] for details of the definitions of the other representations. We will always assume that these canonical representations are used, if not mentioned otherwise.

**Definition 2.3** (Algebraic operations). Let \( f :\!\!: X \Rightarrow Y \) and \( g :\!\!: Z \Rightarrow W \) be multi-valued functions. Then we define the following operations:
Spaces were introduced. The jump \( f \times g \subseteq X \times Z \Rightarrow Y \times W, (f \times g)(x, z) := f(x) \times g(z) \) (product)

(2) \( f \cap g \subseteq X \times Z \Rightarrow Y \sqcup W, (f \cap g)(x, z) := f(x) \sqcup g(z) \) (sum)

(3) \( f \sqcup g \subseteq X \sqcup Z \Rightarrow Y \sqcup W, \) with \( (f \sqcup g)(0, x) := \{0\} \times f(x) \) and
\( (f \sqcup g)(1, z) := \{1\} \times g(z) \) (coproduct)

(4) \( f^* : X^* \Rightarrow Y^*, f^*(i, x) := \{i\} \times f^i(x) \) (finite parallelization)

(5) \( \hat{f} : \subseteq X^N \Rightarrow Y^N, \hat{f}(x_n) := X, f(x_i) \) (parallelization)

In this definition and in general we denote by \( f^i : \subseteq X^i \Rightarrow Y^i \) the \( i \)-th fold product of the multi-valued map \( f \) with itself (\( f^0 \) is the constant function on the canonical singleton). It is known that \( f \cap g \) is the infimum of \( f \) and \( g \) with respect to both strong and ordinary Weihrauch reducibility (see [11], where this operation was denoted by \( \sqcap \)). Correspondingly, \( f \sqcup g \) is known to be the supremum of \( f \) and \( g \) with respect to ordinary Weihrauch reducibility \( \leq_W \) [30]. This turns the partially ordered structure of Weihrauch degrees (induced by \( \leq_W \)) into a lattice, which we call the Weihrauch lattice. The two operations \( f \mapsto \hat{f} \) and \( f \mapsto f^* \) are known to be closure operators in this lattice [11, 30].

There is some useful terminology related to these algebraic operations. We say that \( f \) is a cylinder if \( f \equiv_W \text{id} \times f \) where \( \text{id} : N^N \rightarrow N^N \) always denotes the identity on Baire space, if not mentioned otherwise. For a cylinder \( f \) and any \( g \) the reduction \( g \leq_W f \) is equivalent to \( g \leq_{sW} f \) [11]. We say that \( f \) is idempotent if \( f \equiv_W f \times f \) and strongly idempotent, if \( f \equiv_{sW} f \times f \). We say that a multi-valued function on represented spaces is pointed, if it has a computable point in its domain. For pointed \( f \) and \( g \) we obtain \( f \sqcup g \leq_{sW} f \times g \). The properties of pointedness and idempotency are both preserved under equivalence and hence they can be considered as properties of the respective degrees. For a pointed \( f \) the finite parallelization \( f^* \) can also be considered as idempotent closure since idempotency is equivalent to \( f \equiv_W f^* \) in this case. We call \( f \) parallelizable if \( f \equiv_W \hat{f} \) and it is easy to see that \( f \) is always idempotent. Analogously, we call \( f \) strongly parallelizable if \( f \equiv_{sW} \hat{f} \).

## Compositional Products

While the Weihrauch lattice is not complete, some suprema and some infima exist in general. The following result was proved by the first author and Pauly in [15] and ensures the existence of certain important maxima and minima.

**Proposition 2.4 (Compositional products).** Let \( f, g \) be multi-valued functions on represented spaces. Then the following Weihrauch degrees exist:

\[
f \ast g := \max \{ f_0 \circ g_0 : f_0 \leq_W f \text{ and } g_0 \leq_W g \}\]  \hspace{1cm} \text{(compositional product)}

Here \( f \ast g \) is defined over all \( f_0 \leq_W f \) and \( g_0 \leq_W g \) which can actually be composed (i.e., the target space of \( g_0 \) and the source space of \( f_0 \) have to coincide). In this way \( f \ast g \) characterizes the most complicated Weihrauch degree that can be obtained by first performing a computation with the help of \( g \) and then another one with the help of \( f \). Since \( f \ast g \) is a maximum in the Weihrauch lattice, we can consider \( f \ast g \) as some fixed representative of the corresponding degree. It is easy to see that \( f \times g \leq_W f \ast g \) holds. We can also define the strong compositional product by

\[
f \ast_s g := \sup \{ f_0 \circ g_0 : f_0 \leq_{sW} f \text{ and } g_0 \leq_{sW} g \},
\]

but we neither claim that it exists in general nor that it is a maximum. The compositional products were originally introduced in [13].

## Jumps

In [13] jumps or derivatives \( f' \) of multi-valued functions \( f \) on represented spaces were introduced. The jump \( f' : \subseteq (X, \delta_X) \Rightarrow (Y, \delta_Y) \) of a multi-valued
function \( f : \subseteq (X, \delta_X) \Rightarrow (Y, \delta_Y) \) on represented spaces is obtained by replacing the input representation \( \delta_X \) by its jump \( \delta_X' \):= \( \delta_X \circ \lim \), where
\[
\lim : \subseteq N^N \to N^\mathbb{N}, \langle p_0, p_1, p_2, \ldots \rangle \mapsto \lim_{n \to \infty} p_n
\]
is the limit operation on Baire space \( N^N \) with respect to the product topology on \( N^N \). It follows that \( f' \equiv_{sW} f \circ \lim \) \cite{13, Corollary 5.16}. By \( f^{(n)} \) we denote the \( n \)-fold jump. A \( \delta_X' \)-name \( p \) of a point \( x \in X \) is a sequence that converges to a \( \delta_X \)-name of \( x \). This means that a \( \delta_X' \)-name typically contains significantly less accessible information on \( x \) than a \( \delta_X \)-name. Hence \( f' \) is typically harder to compute than \( f \), since less input information is available for \( f' \).

The jump operation \( f \mapsto f' \) plays a similar role in the Weihrauch lattice as the Turing jump operation does in the Turing semi-lattice. In a certain sense \( f' \) is a version of \( f \) on the “next higher” level of complexity (which can be made precise using the Borel hierarchy \cite{13}). It was proved in \cite{13} that the jump operation \( f \mapsto f' \) is monotone with respect to strong Weihrauch reducibility \( \leq_{sW} \), but not with respect to ordinary Weihrauch reducibility \( \leq_W \). This is another reason why it is beneficial to extend the study of the Weihrauch lattice to strong Weihrauch reducibility.

### 3. Representations of Closed Subsets

In this section we will introduce and discuss some representations of the hyperspace \( \mathcal{A}(X) \) of closed subsets. Mostly, we are interested in the case of computable metric spaces \( X \). We recall that \((X, d, \alpha)\) is called a computable metric space, if \((X, d)\) is a metric space, \( \alpha : \mathbb{N} \to X \) is a sequence that is dense in \((X, d)\) and \( d \circ (\alpha \times \alpha) : \mathbb{N}^2 \to \mathbb{R} \) is computable. In particular, every computable metric space is separable and non-empty. A computable Polish space is just a computable metric space that is additionally complete. The Cauchy representation \( \delta_X \) of a computable metric space is defined by
\[
\delta_X(p) := \lim_{n \to \infty} \alpha p(n),
\]
where \( \text{dom}(\delta_X) \) contains all \( p \in \mathbb{N}^\mathbb{N} \) such that \((\alpha p(n))_n \) converges and such that \((\forall k)(\forall n \geq k) d(\alpha p(n), \alpha p(k)) < 2^{-k}\).

Occasionally we will use the coproduct \( X \sqcup \{\infty\} \) of a computable metric space \((X, d)\) with some additional point \( \infty \) of infinity. This point has distance 1 to all other points and hence it is an isolated point such that “\( x = \infty \)” is decidable. The point of infinity is associated to the space in order to have a “dummy point” that indicates “no information”.

By \((\mathcal{A}_-(X), \psi_-)\) we denote the hyperspace \( \mathcal{A}_-(X) \) of closed subsets of a computable metric space \( X \) with respect to negative information. More precisely, the representation \( \psi_- \) of \( \mathcal{A}_-(X) \) can be defined by
\[
\psi_-(p) := X \setminus \bigcup_{i=0}^\infty B_{p(i)},
\]
where \((B_n)_n \) denotes a standard enumeration of the rational open balls, which can be defined by
\[
B_{(n,k)} := B(\alpha(n), \overline{k}),
\]
where \( \overline{k} \) denotes the \( k \)-th rational number in some standard enumeration of \( \mathbb{Q} \). There are many other equivalent ways of describing this representation \cite{16} and also versions for more general spaces than metric spaces \cite{32}. In case of the metric space of natural numbers \( \mathbb{N} \) equipped with the discrete metric, one can consider...
a name \( p \) with respect to \( \psi_- \) just as an enumeration of the complement of the represented set \( A \).

By \( (A_+(X), \psi_+) \) we denote the hyperspace \( A_+(X) \) of closed subsets of a computable metric space \( X \) with respect to positive information. For a subset \( A \subseteq X \) of a topological space \( X \) we denote by \( \overline{A} \) the closure of \( A \). The representation \( \psi_+ \) of \( A_+(X) \) can be defined by (for some sequence \( (x_n) \))

\[
\psi_+(p) = A : \iff \delta_{X \cup \{\infty\}}^N(p) = (x_n)_n \text{ and } \{x_n : n \in \mathbb{N}\} \cap X = A.
\]

We note that the point \( \infty \) of infinity is added to \( X \) only in order to include the possibility to represent the empty set \( A = \emptyset \). We point out that there are more general versions of the representation \( \psi_+ \) and the one given here is equivalent to other natural versions only for computable Polish spaces \( X \) (see [16] for more details). In case of the metric space of natural numbers \( \mathbb{N} \) equipped with the discrete metric, one can consider a name \( p \) with respect to \( \psi_+ \) just as an enumeration of the represented set.

With the help of \( A_-(X) \) we can introduce the closed choice problem \( C_X \).

**Definition 3.1** (Closed Choice). Let \( X \) be a computable metric space. The closed choice problem of the space \( X \) is defined by

\[
C_X \subseteq A_-(X) \Rightarrow X, A \mapsto A
\]

with \( \text{dom}(C_X) := \{ A \in A_-(X) : A \neq \emptyset \} \).

Intuitively, a realizer of \( C_X \) takes as input a non-empty closed set in negative description (i.e., given by \( \psi_- \)) and it produces an arbitrary point of this set as output. Hence, \( A \mapsto A \) means that the multi-valued map \( C_X \) maps the input \( A \in A_-(X) \) to the set \( A \subseteq X \) as a set of possible outputs.

Besides the closed choice problem we also consider the cluster point problem \( \text{CL}_X \), which we define next.

**Definition 3.2** (Cluster point problem). Let \( X \) be a computable metric space. The cluster point problem of the space \( X \) is defined by

\[
\text{CL}_X \subseteq X^N \Rightarrow X, (x_n)_n \mapsto \{ x \in X : x \text{ is a cluster point of } (x_n)_n \},
\]

where \( \text{dom}(\text{CL}_X) \) contains all sequences \( (x_n)_n \) that have a cluster point.

In [13] Theorem 9.4 the following fact was proved.

**Fact 3.3.** \( C_X \equiv_\text{w} \text{CL}_X \) for every computable metric space \( X \).

To translate positive information into negative information is not computable in general. However, in [9] Proposition 4.2 it was proved that positive information \( \psi_+ \) on closed sets can be translated into negative information \( \psi_- \) with a limit computable function. We can express this result as follows.

**Fact 3.4.** The identity \( \text{id}_{+,-} : A_+(X) \rightarrow A_-(X) \), \( A \mapsto A \) is strongly Weihrauch reducible to \( \text{lim} \), i.e., \( \text{id}_{+,-} \leq_\text{w} \text{lim} \), for every computable metric space \( X \).

We mention that the fact that the reduction is strong directly follows from the fact that \( \text{lim} \) is a cylinder. We will also use the jump \( \psi' \) of the representation \( \psi_- \) and we denote the corresponding hyperspace by \( (A_-(X)' , \psi'_-) \). Fact 3.4 implies \( \psi_+ \leq \psi'_- \), i.e., the identity \( \text{id} : A_+(X) \rightarrow A_-(X)' \) is computable. We note that Facts 3.3 and 1.4 immediately yield upper bounds on \( \text{BCT}_2 \) and \( \text{BCT}_3 \).

---

1\(^{\text{It is known that } \psi_- \text{ is admissible with respect to the upper Fell topology (which corresponds to the Scott topology on the hyperspace of open subsets) [16].}}\)

2\(^{\text{If } X \text{ is a Polish space, then the representation } \psi_+ \text{ is known to be admissible with respect to the lower Fell topology [16].}}\)
Proposition 3.5. \( \text{BCT}_2 \leq_{sW} \text{BCT}_0' \leq_{sW} \lim \text{BCT}_3 \leq_{sW} \text{BCT}_1' \cong_{sW} \text{CL}_N \) for every computable Polish space \( X \).

It is convenient for us to describe the representation \( \psi'_c \) in a different way. For this purpose we introduce the cluster point representation \( \psi_* \) of the set \( \mathcal{A}_c(X) \) of closed subsets of \( X \). This representation \( \psi_* \) represents closed sets as the sets of cluster points of sequences in \( X \). We define

\[
\psi_*(p) = A : \iff \delta^N_{X,\{\infty\}}(p) = (x_n)_{n} \text{ and } \text{CL}_{X,\{\infty\}}(x_n) \cap X = A.
\]

Similarly as in case of \( \psi_* \) we only use the point of infinity \( \infty \) here to allow for a name of the empty set \( A = \emptyset \). Now [13, Corollary 9.5] can be interpreted such that \( \psi_* \) is equivalent to \( \psi'_c \). However, strictly speaking this has only been proved for non-empty sets \( A \) and hence we need to discuss a suitable extension of the proof that includes the empty set \( A \).

Proposition 3.6. Let \( X \) be a computable metric space. Then the identity map \( \text{id} : \mathcal{A}_c(X) \to \mathcal{A}_c(X)' \) is a computable isomorphism, i.e., \( \text{id} \) as well as its inverse are computable. In other words, \( \psi_* \equiv \psi'_c \).

Proof. In the proof of [13, Proposition 9.2] the reduction \( \psi_* \leq \psi'_c \) is described for non-empty sets \( A \subseteq X \). We extend this algorithm to include the case of the empty set as follows. Again we check condition (1) in the cited proof using an enumeration \( (B_i)_n \) of balls with respect to \( X \). If \( A = \emptyset \), then \( x_n = \infty \) for all \( n \geq k \) and some \( k \) and then condition (1) is automatically satisfied and all balls \( B_i \) will be listed, i.e., a name of \( A = \emptyset \) with respect to \( \psi'_c \) will be generated.

In the proof of [13, Theorem 9.4] the reduction \( \psi'_c \leq \psi_* \) is described for non-empty sets \( A \subseteq X \). The algorithm produces certain outputs \( \alpha(h(s,n)) \) and we modify the algorithm such that in any loop we obtain as additional output a name of the point \( \infty \). This guarantees that \( \infty \) is one cluster point of the output, possibly besides other cluster points that remain unchanged. If \( A \) is the empty set, we actually obtain a name of the empty set as output. The correctness proof of the algorithm stays exactly as given in [13]. \( \square \)

In Section 5 we will see another representation \( \psi# \) that is equivalent to \( \psi'_c \) and \( \psi_* \) in the special case of Cantor space \( X = 2^\mathbb{N} \). We note that Fact 4.3 is a consequence of Proposition 3.6.

4. Cluster Points and Boundary Approximation

The purpose of this section is to strengthen Proposition 3.5. We will prove that \( \text{BCT}_2 \equiv_{sW} \text{BCT}_0' \) and \( \text{BCT}_3 \equiv_{sW} \text{BCT}_1' \) for computable perfect Polish spaces. As a preparation for this result we prove a purely topological lemma. We recall that a metric space is called perfect if it has no isolated points.

Lemma 4.1. Let \( X \) be a metric space and let \((x_n)_n \) be a sequence in \( X \). Then

\[
A := \text{CL}_X(x_n)_n \subseteq \{x_n : n \in \mathbb{N}\} =: B.
\]

If \( X \) is perfect, then \( A^\circ = B^\circ \) and, in particular, \( B \) is nowhere dense if \( A \) is so.

Proof. It is clear that \( A \subseteq B \) and hence \( A^\circ \subseteq B^\circ \). We prove that

\[
(1) \quad B \setminus A \subseteq \{x_n : n \in \mathbb{N}\} =: C.
\]

Let \( x \in B \setminus C \). Then there is a strictly increasing sequence \((k_i)_i \) of natural numbers such that \( x = \lim_{i \to \infty} x_{k_i} \in \mathbb{N} \). This proves that \( B \setminus C \subseteq A \) and hence \( B \setminus A \subseteq C \).

Let now \( X \) be perfect. We prove \( B^\circ \subseteq A^\circ \). Let \( x \in B^\circ \), i.e., there is some \( r > 0 \) with \( B(x,r) \subseteq B \). We will show that \( B(x,r) \subseteq A \) follows. Let us assume to the contrary that \( B(x,r) \not\subseteq A \). Then there is some \( y \in B(x,r) \setminus A \). In particular, \( y \) is not
a cluster point of \((x_n)_n\) and hence there is some \(s > 0\) such that \(B(y,s) \subseteq B(x,r)\) and \(B(y,s)\) only contains finitely many \(x_n\). Since \(X\) is perfect, there is some \(z \in B(y,s)\) that is different from all these finitely many \(x_n\) and hence positively bounded away from all \(x_n\), i.e., there is some \(t > 0\) such that \(d(z,x_n) > t\) for all \(n \in \mathbb{N}\). This implies \(z \in B(x,r) \setminus A\) and since \(B(x,r) \subseteq B\), this is a contradiction to \([1]\). Hence, \(B(x,r) \subseteq A\) and hence \(x \in A^o\).

This lemma has the following computational consequence, which roughly speaking says that we can approximate closed sets given as cluster points of sequences by closed sets given as closures of sequences from above and if the underlying space is perfect, then this approximation is tight in the sense that nowhere density is preserved.

**Proposition 4.2.** Let \(X\) be a computable Polish space. Then there is a computable multi-valued map \(M : \mathcal{A}_s(X) \rightarrow \mathcal{A}_s(X)\) such that

1. \(M(A) \subseteq \{B : A \subseteq B\}\)

2. If \(X\) is perfect and \(A \subseteq X\) is nowhere dense, then all \(B \in M(A)\) are nowhere dense too.

**Proof.** Given \(A = \overline{\text{CL}_{X,\{n\}}(x_n)_n} \cap X\), we simply compute \(B = \overline{\{x_n : n \in \mathbb{N}\}} \cap X\) with respect to \(\psi_+\). Then the claim follows from Lemma 4.1 for non-empty \(A\). \(\square\)

Together with Propositions 3.5 and 3.6 we obtain the desired result.

**Theorem 4.3** (Jumps). \(\text{BCT}_0 \equiv_{\text{AW}} \text{BCT}_2\) and \(\text{BCT}_1 \equiv_{\text{AW}} \text{BCT}_3 \equiv_{\text{AW}} \text{CL}_N\) for every computable perfect Polish space \(X\).

The Baire Category Theorem for non-perfect spaces is not particularly interesting, since every dense set in a non-perfect space needs to contain the isolated points. The next proposition shows that in this case \(\text{BCT}_2\) and \(\text{BCT}_3\) are computable.

**Proposition 4.4** (Non-perfect spaces). Let \(X\) be a computable Polish space, which is not perfect. Then \(\text{BCT}_2 \equiv_{\text{AW}} \text{id}_{\{0\}}\) and \(\text{BCT}_3 \equiv_{\text{AW}} \text{id}_N\). In particular, \(\text{BCT}_2\) and \(\text{BCT}_3\) are computable.

**Proof.** Let \((X,d,\alpha)\) be a computable Polish space with an isolated point \(x\). Then \(x\) is in the dense subset range(\(\alpha\)) of the space and hence \(x\) is computable. If \(A \subseteq X\) is a closed set with \(x \in A\), then \(x \in A^o\) and hence \(A^o \neq \emptyset\).

We consider the case of \(\text{BCT}_2\). The aforementioned fact implies that the domain of \(\text{BCT}_2\) only contains sequences \((A_i)\) such that \(x \notin A_i\) for all \(i\) and the constant function that maps all these sequences to \(x\) is a computable selector of \(\text{BCT}_2\). The constant sequence \((A_i)\) with \(A_i = \emptyset\) is a computable point in the domain of \(\text{BCT}_2\).

Altogether, this implies \(\text{BCT}_2 \equiv_{\text{AW}} \text{id}_{\{0\}}\).

We now consider the case of \(\text{BCT}_3\). If \((A_i)\) is a sequence of closed sets \(A_i \subseteq X\) with \(X = \bigcup_{i=0}^{\infty} A_i\), then one of the sets \(A_i\) has to contain the isolated point \(x\) and hence \(A_i^o \neq \emptyset\). In order to realize \(\text{BCT}_3\) we just need to find \(i\) with \(x \in A_i\). Since \(A_i\) is given by a sequence \((x_{ij})_{j \in \mathbb{N}}\) that is dense in it, we need to find \(i,j\) such that \(x_{ij} = x\). Since \(x\) is isolated, there is some \(\varepsilon > 0\) such that for all \(y \in X\) we have \(d(x,y) < \varepsilon \Leftrightarrow x = y\). Hence, we can decide the equality \(x_{ij} = x\) and eventually find \(i,j\) with \(x_{ij} = x\). This proves \(\text{BCT}_3 \leq_{\text{AW}} \text{id}_N\). The reverse reduction is easy to obtain: given \(n \in \mathbb{N}\) we compute a sequence \((A_i)\) of closed sets \(A_i \subseteq X\) such that \(A_i = \emptyset\) for \(i \neq n\) and \(A_n = X\). \(\square\)

This result applies to the case of \(X = \mathbb{N}\). In particular, it shows that Theorem 4.3 does not hold true for non-perfect spaces. We note that \(\text{CL}_N\) is effectively \(\Sigma^0_3\)-measurable, but not \(\Sigma^0_2\)-measurable (the former follows for instance from [13], Corollary 9.2) which implies the statement \(\text{CL}_N \leq_{\text{W}} \text{lim} \circ \text{lim}\) and the latter follows
from [13, Proposition 12.5], which implies the stronger statement that not even $\text{CL}_{(0,1)}$ is $\Sigma^0_2$ measurable. Altogether, we obtain the following dichotomy that characterizes the perfect spaces among the computable Polish spaces.

**Corollary 4.5 (Dichotomy).** Let $X$ be a computable Polish space. Then $X$ is perfect if and only if $\text{BCT}_3$ is not computable (in which case $\text{BCT}_3 \equiv_{\text{sw}} \text{CL}_N$).

Analogously, an arbitrary Polish space is perfect if and only if $\text{BCT}_3$ is discontinuous. Finally, we can derive other interesting consequences from Proposition 4.2. In [9, Theorem 9.3] the following result was proved. For a subset $A \subseteq X$ of a topological space $X$ we denote by $\partial A$ the boundary of $A$.

**Fact 4.6 (Boundary).** $\partial : A_-(X) \to A_+(X), A \mapsto \partial A$ is limit computable for every computable metric space $X$, i.e., $\partial \leq_{\text{sw}} \lim$.

While the boundary map of type $\partial : A_-(X) \to A_+(X)$ is $\Sigma^0_2$ hard for Cantor space and not even Borel measurable in case of Baire space [9, Theorem 9.3], it turns out that we can approximate the boundary from above in the following sense.

**Corollary 4.7 (Boundary approximation).** The map $P : A_- \subseteq X \Rightarrow A_+(X)$ with $P(A) := \{B : \partial A \subseteq B, B \text{ nowhere dense}\}$ is computable for all computable perfect Polish spaces $X$.

This follows from Fact 4.6 together with Proposition 4.2 given that the boundary of a closed set is always nowhere dense.

## 5. Parallelizability

In this section we want to prove, among other things, that $\text{BCT}_0$ and $\text{BCT}_2$ are both parallelizable. Since $\text{BCT}_1 \equiv_{\text{sw}} \text{CL}_N$ by Fact 4.4 and $\text{BCT}_3 \equiv_{\text{sw}} \text{CL}_N$ by Theorem 5.3 for perfect Polish spaces, it is clear that $\text{BCT}_1$ and $\text{BCT}_3$ are not parallelizable. In fact, we obtain the following corollary.

**Corollary 5.1.** $\overline{\text{BCT}_1} \equiv_{\text{sw}} \lim$ and $\overline{\text{BCT}_3} \equiv_{\text{sw}} \lim'$ for all computable perfect Polish spaces.

**Proof.** We have $\overline{\text{CL}_N} \equiv_{\text{sw}} \lim$ by [13, Example 3.10] (where the equivalence is strict since both problems are cylinders) and hence $\overline{\text{CL}_N} \equiv_{\text{sw}} \lim'$ since parallelization commutes with jumps by [13, Proposition 5.7(3)].

The first statement that $\overline{\text{BCT}_1} \equiv_{\text{sw}} \lim$ does not require perfectness and in case of non-perfect spaces one obtains $\text{BCT}_3 \equiv_{\text{sw}} \text{id}$ by Corollary 4.5.

We recall that in [13] a problem $f$ was called $\omega$–discriminative if $\text{ACC}_N \leq_W f$ and $\omega$–indiscriminative otherwise. Here $\text{ACC}_N$ is the problem $C_N$ restricted to $\text{dom}(\text{ACC}_N) = \{A : |N \setminus A| \leq 1\}$; hence the name “all-or-co-unique choice”. A problem $f$ is called discriminative, if $C_2 \equiv_{\text{sw}} \text{LLPO} \leq_W f$ and indiscriminative otherwise. Since $\text{ACC}_N < C_2$, it is clear that discriminative implies $\omega$–discriminative, but not conversely.

It is easy to see that $\text{BCT}_1$ and $\text{BCT}_3$ are both discriminative (where we consider the latter for perfect $X$). This follows from

$$C_2 \leq_{\text{sw}} C_N \equiv_{\text{sw}} \text{BCT}_1 \leq_{\text{sw}} \text{CL}_N \equiv_{\text{sw}} \text{BCT}_3.$$  

On the other hand, $\text{BCT}_0$ and $\text{BCT}_2$ are both $\omega$–indiscriminative and hence also indiscriminative: since $\text{BCT}_0$ and $\text{BCT}_2$ are each densely realized$^3$ by the Baire Category Theorem ([12]) itself, this follows from [13, Proposition 4.3]. Moreover,

$^3$A notion introduced in [13], which roughly speaking, says that the image of $\text{BCT}_0$ and $\text{BCT}_2$ is densely covered over all realizers.
every jump of BCT$_0$ or BCT$_2$ is also $\omega$-indiscriminative, since it is merely a property of the image.

**Proposition 5.2.** BCT$_{i}^{(n)}$ and BCT$_j^{(n)}$ are both densely realized and hence $\omega$-indiscriminative for all $n \in \mathbb{N}$ and each computable Polish space $X$.

This property can even be transferred to intersections of these problems, which we formally define next.

**Definition 5.3** (Intersection). Let $f : \subseteq X \Rightarrow Z$ and $g : \subseteq Y \Rightarrow Z$ be multi-valued functions on represented spaces. Then we define $f \cap g : \subseteq X \times Y \Rightarrow Z$ by

$$(f \cap g)(x, y) := f(x) \cap g(y)$$

and dom$(f \cap g) := \{(x, y) \in X \times Y : f(x) \cap g(y) \neq \emptyset\}$. Let $f_i : \subseteq X \Rightarrow Y$ be a sequence of multi-valued functions on represented spaces. Then we define $\bigcap_{i=0}^{\infty} f_i : \subseteq X^\mathbb{N} \Rightarrow Y^\mathbb{N}$ by

$$\left(\bigcap_{i=0}^{\infty} f_i\right)(x)_i := \bigcap_{i=0}^{\infty} f_i(x_i)$$

and dom$(\bigcap_{i=0}^{\infty} f_i) := \{(x)_i : \bigcap_{i=0}^{\infty} f_i(x_i) \neq \emptyset\}$.

We mention that in case of dom$(f \cap g) = \text{dom}(f) \times \text{dom}(g)$ and dom$(\bigcap_{i=0}^{\infty} f) = \text{dom}(f_i)^\mathbb{N}$ we obtain

$$f \times g \leq_{sW} f \cap g \quad \text{and} \quad \bigcap_{i=0}^{\infty} f_i \leq_{sW} \bigcap_{i=0}^{\infty} f_i$$

respectively. For pointed $f, g$ we also have $f \cup g \leq_{sW} f \times g$, which implies $f \leq_{sW} f \cap g$ and $g \leq_{sW} f \cap g$. We note that BCT$_0$ and BCT$_2$ are both pointed, since they contain the constant sequence of the empty set in their domains. Due to the Baire Category Theorem itself we can mix the two problems BCT$_0$ and BCT$_2$ and their jumps without losing any points in the domain. We make this statement precise.

**Lemma 5.4.** For a fixed computable Polish spaces, we have that

1. dom$(\text{BCT}_i^{(n)} \cap \text{BCT}_j^{(k)}) = \text{dom}(\text{BCT}_i^{(n)}) \times \text{dom}(\text{BCT}_j^{(k)})$ and
2. dom$(\bigcap_{i=0}^{\infty} \text{BCT}_j^{(n)}) = \text{dom}(\text{BCT}_j^{(n)})^\mathbb{N}$

for all $i, j \in \{0, 2\}$ and $n, k \in \mathbb{N}$.

All the intersections mentioned in this lemma are also densely realized. We mention that it follows from Proposition 5.2 and [14, Proposition 4.3] that BCT$_0^{(n)}$ and BCT$_2^{(n)}$ are all not cylinders. We obtain the following result.

**Proposition 5.5** (Parallelizability). BCT$_0^{(n)}$ and BCT$_2^{(n)}$ are strongly parallelizable and strongly idempotent for every computable Polish space and $n \in \mathbb{N}$.

**Proof.** The map $K$ with $((A_{j,i})_{i \in \mathbb{N}})_{j \in \mathbb{N}} \mapsto (A_{j,i})_{(i,j) \in \mathbb{N}}$ that maps sequences of sequences in $\mathcal{A}(X)$ to a single sequence in $\mathcal{A}(X)$ is computable with respect to positive and negative information as well as the map $H$ that maps a point $x \in X$ to the constant sequence with value $x$. Since

$$\bigcap_{j=0}^{\infty} \left( X \setminus \bigcup_{i=0}^{\infty} A_{j,i} \right) = X \setminus \bigcup_{i=0}^{\infty} \bigcup_{j=0}^{\infty} A_{j,i},$$

we have that for each $k \in \{0, 2\}$

$$(\text{BCT}_{k}(A_{j,i})_{i \in \mathbb{N}})^{\mathbb{N}} = \left( \bigcap_{j=0}^{\infty} \text{BCT}_{k}(A_{j,i})_{i \in \mathbb{N}} \right)^{\mathbb{N}} \subseteq \text{BCT}_{k}((A_{j,i})_{i \in \mathbb{N}})_{j \in \mathbb{N}},$$
and so $H \circ BCT_k \circ K(A) \subseteq BCT_k(A)$ for each sequence of sequences $A$. This proves the claim on strong parallelisability for $BCT_k$. For the general case of $BCT_k^{(n)}$ with $n \in \mathbb{N}$ we additionally note that $[\delta^{(n)}]^i \equiv (\delta^i)^3$ for every representation $\delta$. Strong idempotency follows from strong parallelisability since $BCT_k^{(n)}$ is pointed for all $n \in \mathbb{N}$.

\[\square\]

6. The Baire Category Theorem on Perfect Polish Spaces

In this section we prove that the Baire Category Theorem $BCT_0$ defines a single equivalence class for all computable perfect Polish spaces, which include Cantor space $2^\mathbb{N}$ and Baire space $\mathbb{N}^\mathbb{N}$. By Fact \([1,3]\) this is already known for $BCT_1$ and by Theorem \([1,9]\) the same applies to $BCT_2$ and $BCT_3$. We subdivide the proof essentially into the following reduction chain

$$BCT_{0,X} \leqsw BCT_{0,0} \leqsw BWT_{0,2^n} \leqsw BCT_{0,X}$$

and we start with a special version of the Cauchy representation.

**Lemma 6.1** (Cauchy representation). Let $(X,d,\alpha)$ be a computable Polish space. Then there exists a computable, surjective and total map $\delta: \mathbb{N}^\mathbb{N} \rightarrow X$ such that $\delta^{-1}(A)$ is nowhere dense in $\mathbb{N}^\mathbb{N}$ for every nowhere dense $A \subseteq X$.

**Proof.** We consider the restricted Cauchy representation $\tilde{\delta} : \subseteq \mathbb{N}^\mathbb{N} \rightarrow X$, $p \mapsto \lim_{n \rightarrow \infty} \alpha(p(n))$, with domain

$$\text{dom}(\tilde{\delta}) := \{p \in \mathbb{N}^\mathbb{N} : (\forall k)(\forall n > k) d(\alpha(p(n)), \alpha(\tilde{\delta}(p))) \leq 2^{-k-1}\}.$$  

The map $\tilde{\delta}$ is well-defined and surjective since $X$ is complete. Since $\tilde{\delta}$ is a restriction of the usual Cauchy representation $\delta_X$ as defined in Section 8 it follows that $\tilde{\delta}$ is computable (with respect to $\delta_X$). There exists a total computable function $f: \mathbb{N}^\mathbb{N} \rightarrow \mathbb{N}^\mathbb{N}$ that satisfies

$$f(p)(n) = \begin{cases} p(n) & \Rightarrow (\forall k < n) d(\alpha(p(n)), \alpha(f(p)(k))) < 2^{-k-1} \\ f(p)(n-1) & \Rightarrow (\exists k < n) d(\alpha(p(n)), \alpha(f(p)(k))) > 2^{-k-2} \end{cases}$$

for all $p \in \mathbb{N}^\mathbb{N}$ and $n \in \mathbb{N}^\mathbb{N}$. We obtain $\text{range}(f) \subseteq \text{dom}(\tilde{\delta})$ and hence $\delta := \tilde{\delta} \circ f$ is total. It is clear that $\delta$ is also computable. We note that $\tilde{\delta}$ restricted to $D := \{p \in \mathbb{N}^\mathbb{N} : (\forall k)(\forall n > k) d(\alpha(p(n)), \alpha(\tilde{\delta}(p))) \leq 2^{-k-2}\}$ is still surjective and $f(D) = D$. Hence $\tilde{\delta}$ is surjective too. Finally, let $A \subseteq X$ be such that $\delta^{-1}(A)$ is somewhere dense. Then there is a word $w \in \mathbb{N}^*$ such that $w\mathbb{N}^\mathbb{N} \subseteq \delta^{-1}(A)$. We let $p := w000...$ and $a_k := f(p)(k)$ for all $k = 0,...,n$, where $n := |w| - 1$. Then $\bigcap_{k=0}^{n} B(\alpha(a_k),2^{-k-1})$ is a nonempty subset of $A$, which implies that $A$ is somewhere dense. \[\square\]

Hence we obtain the following result.

**Proposition 6.2.** $BCT_{0,X} \leqsw BCT_{0,0}$ for every computable Polish space $X$.

**Proof.** Lemma 6.1 implies that the map $\delta^{-1} : \mathcal{A}_-(X) \rightarrow \mathcal{A}_-(\mathbb{N}^\mathbb{N})$, $A \mapsto \delta^{-1}(A)$ is well-defined, it is computable since $\delta$ is computable, it preserves nowhere density and it maps non-empty sets to non-empty sets since $\delta$ is surjective. Now, given a sequence $(A_i)_i$ of nowhere dense closed sets, we can compute $(\delta^{-1}(A_i))$, and if $p \in BCT_{0,0}(\delta^{-1}(A_i)) = \bigcup_{i=0}^{\infty} (\mathbb{N}^\mathbb{N} \setminus \delta^{-1}(A_i))$, then we obtain

$$\delta(p) \in \bigcup_{i=0}^{\infty} (\delta(\mathbb{N}^\mathbb{N} \setminus \delta^{-1}(A_i))) = \bigcup_{i=0}^{\infty} (X \setminus A_i) = BCT_{0,X}(A_i).$$

4 We note that this equation does not define $f$, since the conditions overlap; however the conditions can be verified and depending on which condition is met first, the algorithm for $f$ chooses the corresponding case.
By Lemma 6.1, $\delta$ is computable and hence $\text{BCT}_{0,X} \leq_{\text{SW}} \text{BCT}_{0,\mathbb{N}^\omega}$.

A map $f : X \mapsto Y$ is called a computable embedding if it is injective and both $f$ and its partial inverse $f^{-1}$ are computable. In [9], a computable metric space was called rich if there is a computable embedding $\iota : 2^\mathbb{N} \mapsto X$. In [9, Proposition 6.2] the following was proved using a Cantor scheme.

**Fact 6.3.** Every perfect computable Polish space is rich.

For rich computable Polish spaces we obtain the following reduction.

**Proposition 6.4.** $\text{BCT}_{0,2^\omega} \leq_{\text{SW}} \text{BCT}_{0,X}$ for every rich computable Polish space $X$.

**Proof.** Let $\iota : 2^\mathbb{N} \mapsto X$ be a computable embedding. Then $\iota$ preserves nowhere density: if $A \subseteq 2^\mathbb{N}$ is such that $\iota(A)$ is somewhere dense, then there exists some non-empty open $U \subseteq X$ with $U \subseteq \iota(A)$ and since $\iota$ is injective and continuous we obtain that $\iota^{-1}(U) \subseteq A$ is non-empty and open. Hence, $A$ is somewhere dense. Finally, the map $J : \text{A}_-(2^\mathbb{N}) \mapsto \text{A}_-(X), A \mapsto \iota(A)$ is computable by [9, Theorem 3.7], since $\iota(2^\mathbb{N})$ is computably compact and hence, in particular, co-c.e. closed. Now given a sequence $(A_i)_i$ of nowhere dense closed sets, we can compute $(J(A_i))_i$ and if $x \in \text{BCT}_{0,X}(J(A_i)) = \bigcup_{i=0}^\infty (X \setminus \iota(A_i))$, then we obtain

$$\iota^{-1}(x) \in \iota^{-1}\left(\bigcup_{i=0}^\infty (X \setminus \iota(A_i))\right) = \bigcup_{i=0}^\infty (2^\mathbb{N} \setminus A_i) = \text{BCT}_{0,2^\omega}(A_i).$$

Since $\iota^{-1}$ is computable, we obtain $\text{BCT}_{0,2^\omega} \leq_{\text{SW}} \text{BCT}_{0,X}$.

In particular, this applies to perfect computable Polish spaces $X$ by Fact 6.3. Finally, we relate the Baire Category Theorem $\text{BCT}_0$ for Baire and Cantor space by the following result. We use the notion of a c.e. comeager set as defined later in Definition 6.5.

**Lemma 6.5 (Embedding of Baire space into Cantor space).** The map $$\iota : \mathbb{N}^\mathbb{N} \mapsto 2^\mathbb{N}, p \mapsto 1^{p(0)}01^{p(1)}01^{p(2)}...$$

is a computable embedding with a c.e. comeager range($\iota$) and the map $$I : \text{A}_-(\mathbb{N}^\mathbb{N}) \mapsto \text{A}_-(2^\mathbb{N}), I(A) := \{B : \iota(A) \subseteq B \text{ and } B \text{ is nowhere dense}\}$$

is computable, restricted to $\text{dom}(I) := \{A : A \text{ nowhere dense}\}$.

**Proof.** (1) It is clear that $\iota$ and its partial inverse are computable. (2) The sequence $(U_n)_n$ with $U_n := \{q \in 2^\mathbb{N} : (3k \geq n) (q(k) = 0)\}$ is a computable sequence of dense c.e. open subsets $U_n \subseteq 2^\mathbb{N}$ and range($\iota$) = $\bigcap_{n=0}^\infty U_n$. Hence $(2^\mathbb{N} \setminus U_n)_n$ is a computable sequence in $\text{A}_-(2^\mathbb{N})$ and range($\iota$) is c.e. comeager. (3) We prove that $\iota(\overline{A}) \subseteq 2^\mathbb{N}$ is nowhere dense for all closed and nowhere dense $A \subseteq \mathbb{N}^\mathbb{N}$. We define a word function $J : \mathbb{N}^* \mapsto \{0,1\}^*$ by $J(a_0...a_n) := 1^{a_0}01^{a_1}0...1^{a_n}0$ for all $a_0,...,a_n \in \mathbb{N}$. Since $J$ is monotone, we obtain for all $v \in \mathbb{N}^*$ that $J(v)2^\mathbb{N} \cap \iota(A) = \emptyset$ if $v\mathbb{N} \cap A = \emptyset$. Let now $w\mathbb{N} \not\subseteq A$ for $w \in \mathbb{N}^*$. Then there is some $v \in \mathbb{N}^*$ with $w \subseteq v$ and $v\mathbb{N} \cap A = \emptyset$ and hence $J(v)2^\mathbb{N} \cap \iota(A) = \emptyset$, which implies $J(w)2^\mathbb{N} \not\subseteq \iota(A)$. In other words, if $\iota(A)$ is somewhere dense, then $A$ is so. (4) The fact that the partial inverse $\iota^{-1} : 2^\mathbb{N} \mapsto \mathbb{N}^\mathbb{N}$ is computable implies that for every closed $A \subseteq \text{A}_-(\mathbb{N}^\mathbb{N})$ we can compute some closed $B \in \text{A}_-(2^\mathbb{N})$ such that $B \cap \text{range}(\iota) = \iota(A)$. Since $\text{range}(\iota)$ is dense, $B^\circ = (B \cap \text{range}(\iota))^\circ = (\iota(A))^\circ$. Hence, $B$ is nowhere dense if $\iota(A)$ is so. Altogether, this shows that $I$ is computable.

We can now prove the following result.

**Theorem 6.6 (Cantor and Baire).** $\text{BCT}_{0,2^\omega} \equiv_{\text{SW}} \text{BCT}_{0,\mathbb{N}^\omega}$ and $\text{BCT}_{2,2^\omega} \equiv_{\text{SW}} \text{BCT}_{2,\mathbb{N}^\omega}$.
Proof. We only need to prove that $\text{BCT}_{0, \aleph_0} \leq_{\text{sw}} \text{BCT}_{0, 2^{n}}$, since the second statement follows from Theorem 4.3 and $\text{BCT}_{0, 2^n} \leq_{\text{sw}} \text{BCT}_{0, \aleph_0}$ follows from Proposition 6.2. To this end, let $(A_i)$ be a sequence of nowhere dense closed sets in $\mathcal{A}_-(\mathbb{N}^{\omega})$. Then we can compute by Lemma 6.3 a sequence $(B_i)$ of nowhere dense closed sets in $\mathcal{A}_-(2^{n})$ such that $\iota(A_i) \subseteq B_i$. Moreover, we can compute a sequence $(C_i)$ of nowhere dense closed sets in $\mathcal{A}_-(2^{n})$ such that $2^{n} \setminus \text{range}(i) = \bigcup_{i=0}^{\infty} C_i$. If 

$$p \in \text{BCT}_{0, 2^n}(B_i \cup C_i)_i = 2^{n} \setminus \bigcup_{i=0}^{\infty} (B_i \cup C_i) \subseteq \text{range}(i) \setminus i \left( \bigcup_{i=0}^{\infty} A_i \right),$$

then $\iota^{-1}(p) \in \mathbb{N}^{\omega} \setminus \bigcup_{i=0}^{\infty} A_i = \text{BCT}_{0, \aleph_0}(A_i)_i$. Hence $\text{BCT}_{0, \aleph_0} \leq_{\text{sw}} \text{BCT}_{0, 2^n}$. □

We can summarize the other results of this section in the following corollary.

Corollary 6.7 (Perfect Polish spaces). $\text{BCT}_{i, X} \equiv_{\text{sw}} \text{BCT}_{i, \aleph_0}$ for each computable perfect Polish space $X$ and $i \in \{0, 1, 2, 3\}$.

Proof. By Fact 1.3 the claim is already known for $\text{BCT}_1$. If we can prove the claim for $\text{BCT}_0$, then the claim follows for $\text{BCT}_2$ and $\text{BCT}_3$ by Theorem 1.3 in order to prove the claim for $\text{BCT}_0$ it suffices to prove

$$\text{BCT}_{0, X} \leq_{\text{sw}} \text{BCT}_{0, \aleph_0} \leq_{\text{sw}} \text{BWT}_{0, 2^n} \leq_{\text{sw}} \text{BCT}_{0, X},$$

which follows from Propositions [5.2 [6.2, 6.3] Fact 6.6 and Theorem 6.6. □

We mention that many typical spaces, such as $2^{\mathbb{N}}$, $\mathbb{N}^{\omega}$, $[0, 1]^{-\mathbb{N}}$, $\ell_2$, and $C[0, 1]$, are computable perfect Polish spaces with their usual metrics.

7. Dense Versions of the Baire Category Theorem

In view of the strong version of the Baire Category Theorem that is formulated in Theorem 1.2, it is also natural to consider versions of $\text{BCT}_0$ and $\text{BCT}_2$ where the output is not just a single point, but an entire sequence that is dense in the complement of the given union of closed sets. We define such versions more precisely now.

Definition 7.1 (Dense Baire Category Theorem). Let $X$ be a computable Polish space. We introduce the operations $\text{DBCT}_{0, X} \subseteq \mathcal{A}_-(X)^{\aleph_0} \Rightarrow X^{\omega}$ and $\text{DBCT}_{2, X} \subseteq \mathcal{A}_+(X)^{\aleph_0} \Rightarrow X^{\omega}$ with 

- $\text{DBCT}_{0, X}(A_i) := \text{DBCT}_{2, X}(A_i) := \{(x_i)_i : (x_i)_i \text{ is dense in } X \setminus \bigcup_{i=0}^{\infty} A_i\}$,

- $\text{dom}(\text{DBCT}_{0, X}) := \text{dom}(\text{DBCT}_{2, X}) := \{(A_i) : (\forall i) A_i^0 = \emptyset\}$. 

Even though prima facie $\text{DBCT}_0$ and $\text{DBCT}_2$ might appear to be stronger than $\text{BCT}_0$ and $\text{BCT}_2$, respectively, this is not actually the case, as we will show now at least for perfect spaces. Firstly, for every computable metric space $(X, d, \alpha)$ we use the abbreviation $B_{n, k} := B(\alpha(n), 2^{-k})$ (which denotes the closure of the given open ball, not the corresponding closed ball). We note that these balls induce computable Polish spaces in a uniform way, provided $(X, d, \alpha)$ is a computable Polish space.

Lemma 7.2 (Closure of balls). Let $(X, d, \alpha)$ be a computable Polish space. Then $(B_{n, k}, d|_{B_{n, k}}, \alpha_{n, k})$ is a computable Polish space for all $n, k \in \mathbb{N}$, where $(\alpha_{n, k})_{(n, k)}$ is a computable sequence of maps $\alpha_{n, k} : \mathbb{N} \to X$ such that $\text{range}(\alpha_{n, k})$ is dense in $B_{n, k}$. Moreover, the sequence $(\iota_{n, k})_{(n, k)}$ of embeddings $\iota_{n, k} : B_{n, k} \hookrightarrow X$ is computable too.

Proof. We just choose $\alpha_{n, k}(0) := \alpha(n)$ and then we continue inductively. We let $\alpha_{n, k}(t+1) := \alpha(m)$ if within $t$ time steps and in some systematic way we can find a fresh value $m$ that has not been used before to define any of the points $\alpha_{n, k}(s)$ with $s \leq t$ and such that $d(\alpha(n), \alpha(m)) < 2^{-k}$. Otherwise, if we can find no such
m, then we let \( \alpha_{n,k}(t+1) = \alpha(n) \). In this way we obtain a computable sequence \((\alpha_{n,k}(n,k))\) with the desired properties. We note that the algorithm guarantees that there exists a computable function \( f : \mathbb{N} \to \mathbb{N} \) such that \( \alpha_{n,k}(m) = f(n, k, m) \) for all \( n, k, m \in \mathbb{N} \). Hence, it follows that the sequence \((\iota_{n,k}(n,k))\) of embeddings is computable.

By a uniform version of Lemma 6.1 and using the fact that \( \text{BCT}_{0, N^n} \) is parallelizable, we can now obtain the following conclusion.

**Proposition 7.3** (Dense Baire Category Theorem). \( \text{DBCT}_{0,X} \leq_{sW} \text{BCT}_{0,N^n} \) for every computable Polish space \( X \).

**Proof.** Firstly, we note that by a uniform application of the method described in the proof of Lemma 6.1, where we use the dense sequences \( \alpha_{n,k} \) according to Lemma 7.2, we obtain a computable sequence \((\delta_{n,k}(n,k))\) of maps \( \delta_{n,k} : \mathbb{N}^n \to B_{n,k} \) such that \( \delta_{n,k}^{-1}(A) \) is nowhere dense in \( \mathbb{N}^n \) for every nowhere dense \( A \subseteq B_{n,k} \). Given a sequence \( \{A_i\}_i \) of nowhere dense subsets \( A_i \subseteq X \), we can uniformly compute sequences \( \{A_{n,k,i}\}_i \) with \( A_{n,k,i} := \delta_{n,k}^{-1}(A_i) = A_i \cap B_{n,k} \) by Lemma 7.2, which are nowhere dense in \( B_{n,k} \). By Proposition 5.5 this implies

\[
\text{DBCT}_{0,X} \leq_{sW} \bigcap_{(n,k)=0}^{\infty} BCT_{0,B_{n,k}} \leq_{sW} \text{BCT}_{0,N^n} \leq_{sW} \text{BCT}_{0,N^n}.
\]

Using Proposition 7.3, Theorem 4.3, Corollary 6.7, and the observation that \( \text{DBCT}_{2,X} \leq_{sW} \text{DBCT}_{0,X} \) holds by Fact 3.4 and the fact that \( \text{BCT}_{i,X} \leq_{sW} \text{DBCT}_{i,X} \), obviously holds, we obtain the desired main result of this section.

**Corollary 7.4** (Dense Baire Category Theorem). \( \text{DBCT}_{i,X} \equiv_{sW} \text{BCT}_{i,X} \) for every computable perfect Polish space \( X \) and \( i \in \{0, 2\} \).

### 8. \( \Pi^0_1 \)-Genericity

The purpose of this section is to classify yet another version of the Baire Category Theorem that has been called \( \Pi^0_1 \)-genericiy [23, page 5823]. Essentially, \( \Pi^0_1 \) is a version of the non-discrete Baire Category Theorem on Cantor space with a variant \( \psi_{\#} \) of the cluster point representation \( \psi_* \) on the input side. In the following we use the representation \( \psi_* \) of \( \text{A}_\#(\{0, 1\}^\ast) \). We define the representation \( \psi_{\#} \) of the set \( \text{A}_\#(2^\mathbb{N}) \) of closed subsets of \( 2^\mathbb{N} \) by

\[
\psi_{\#}(p) := 2^\mathbb{N} \setminus \bigcup_{w \in \psi_*(p)} w 2^\mathbb{N}.
\]

So a closed subset of \( 2^\mathbb{N} \) is described here as the complement of a union of balls given by words, which are presented negatively, i.e., by listing all words which are not used. In terms of this representation \( \psi_{\#} \) of closed sets \( \Pi^0_1 \)-genericiy is just the corresponding variant of \( \text{BCT}_0 \) or \( \text{BCT}_2 \).

**Definition 8.1.** Let \( \Pi^0_1 : \text{A}_\#(2^\mathbb{N}) \equiv 2^\mathbb{N} \) be defined by

\[
\Pi^0_1(A_i) := \bigcap_{i=0}^{\infty} 2^\mathbb{N} \setminus A_i
\]

with \( \text{dom}(\Pi^0_1) := \{(A_i)_i : (\forall i) A^c_i \neq \emptyset\} \).

As it turns out, this variant of the Baire Category Theorem is equivalent to \( \text{BCT}_0 \). This follows from the following result (which is related to the fact that \( \Pi^0_1 \) and \( \Delta^0_2 \) are equivalent, as mentioned following [22, Definition 9.44]).
Proposition 8.2. \( \text{id} : A_\cdot(2^N)^* \to A_\cdot(2^N) \) is a computable isomorphism, i.e., \( \text{id} \) as well as its inverse are computable.

Proof. It follows from Fact 3.4 applied to the space \( X = \{0,1\}^* \), that the inverse of \( \text{id} \) is computable. We need to prove that \( \text{id} \) is computable too. Given a double list \((w_{ij})_{i,j}\) of words \( w_{ij} \in \{0,1\}^* \) such that \( w_i := \lim_{j \to \infty} w_{ij} \) exists (with respect to the discrete metric on \( \{0,1\}^* \)), we need to compute a list \((u_i)_{i} \) of words with \( E := \{ v \in \{0,1\}^* : (\forall i) \vDash_{ij} \} \) such that \( U := \bigcup_{i=0}^{\infty} u_i 2^N = \bigcup_{v \in E} v 2^N \). We describe an algorithm that generates a corresponding list \((u_i)_{i} \), given \((w_{ij})_{i,j}\). The algorithm works in stages \( s = \langle i, j \rangle = 0, 1, 2, \ldots \) and for bookkeeping purposes it works with finite sets \( F_i \subseteq \{0,1\}^* \) of “forbidden words” for each column \( i \), which are changed during the course of the computation. Initially all these sets are empty. In stage \( s = \langle i, j \rangle \) we inspect the word \( w_{ij} \) with the following algorithm:

1. If \( j = 0 \) or \( w_{ij-1} \neq w_{ij} \) or \( F_i = \emptyset \), i.e., if we have a new word in column \( i \) or the forbidden word list of column \( i \) is empty, then column \( i \) “requires attention” and we set \( F_i := \{ u_0, \ldots, u_k \} \), where the \( u_i \) are words that are longer than any word \( v \) that has been written to the output yet, with \( k \) and the \( u_i \) minimal, and \( \bigcup_{i=0}^{k} u_i 2^N = w_{ij} 2^N \). We also set \( F_k := \emptyset \) for all \( k > i \), i.e., we clear all forbidden word lists of lower priority.

2. We check all the words \( v \in \{0,1\}^* \) with number less or equal to \( s \) (with respect to some standard enumeration of words) and we write each corresponding word \( v \) to the output, provided that \( v \notin \bigcup_{i=0}^{k} F_i \) (which we can check since this set is finite at any time).

3. If no word \( v \) has been written in the previous step, then we write the empty word to the output.

Since the words in each column converge, each column \( i \) requires attention at most finitely many times. When column \( i \) requires attention for the last time at stage \( s = \langle i, j \rangle \), then the forbidden word list \( F_i \) will be filled with words that ensure \( w_{ij} = w_i \) is covered by \( E \) in the sense that \( w_i 2^N \subseteq \bigcup_{v \in E} v 2^N \). On the other hand, up to stage \( s \) all words \( v \) up to number \( s \) are written to the output, provided they are not included in \( \bigcup_{i=0}^{s} F_i \). This finally ensures \( U = \bigcup_{v \in E} v 2^N \). \( \square \)

From this proposition and Corollary 6.7 we directly get the desired corollary.

Corollary 8.3. \( \Pi^0_G \equiv_{SW} \text{BCT}_2 \equiv_{SW} \text{BCT}'_0 \) for every computable perfect Polish space.

9. 1–Genericty

In this section we compare \( \text{BCT}_0 \) and \( \text{BCT}_2 \) with the problem \( 1\text{-GEN} \) of 1–genericty. If not mentioned otherwise, then all \( \text{BCT}_0 \) and \( \text{BCT}_2 \) in this section are considered with respect to Cantor space \( 2^N \), which is not an essential restriction by Corollary 6.7, but more convenient since 1–genericty is typically considered in Cantor space.

We recall some definitions. For one, we assume that we have some effective standard enumeration \((U^q_i)_{i \in \mathbb{N}} \) of the subsets \( U^q_i \subseteq 2^N \) that are c.e. open in \( q \in 2^N \) (and which can be defined by \( U^q_i := \{ p \in 2^N : \varphi^{(p,q)}_i(0) \downarrow \} \)). Then the Turing jump operator \( J^q \) relatively to \( q \) can be defined by

\[
J^q : 2^N \to 2^N, J^q(p)(i) := \begin{cases} 1 & \text{if } p \in U^q_i \\ 0 & \text{otherwise} \end{cases}
\]

Now a point \( p \in 2^N \) is called 1–generic in \( q \in 2^N \) if for all \( i \in \mathbb{N} \) there exists some \( w \sqsubseteq p \) such that \( w 2^N \subseteq U^q_i \) or \( w 2^N \cap U^q_i = \emptyset \). As observed in [5 Lemma 9.3] a point \( p \in 2^N \) is 1–generic in \( q \) if and only if it is a point of continuity of \( J^q \). We call \( p \) just 1–generic if it is 1–generic in some computable \( q \in 2^N \). We use the concept of 1–genericty in order to define the problem 1–GEN of 1–genericty.
**Definition 9.1** (Genericity). We define 1GEN : 2N \rightarrow 2N by

\[
1\text{-GEN}(q) := \{ p : p \text{ is 1–generic in } q \}
\]

for all p ∈ 2N.

If p ≤_T q, then 1GEN(q) ⊆ 1GEN(p). The points p which are 1–generic relative to q can also be described as follows. For a subset A ⊆ X we denote by A^c = X \setminus A the complement of A.

**Lemma 9.2** (Generic points). For all p ∈ 2N we obtain:

\[
1\text{-GEN}(p) = \bigcap_{i=0}^{\infty} \left( U_i^p \cup \overline{U_i^p}^c \right) = \bigcap_{i=0}^{\infty} (2^N \setminus \partial U_i^p).
\]

Here ∂U_i^p = ∂(U_i^p)^c and ((U_i^p)^c)_i is a computable sequence in A_c(2N). Since the boundaries ∂U_i^p are nowhere dense, it follows that the set of 1–generic points in p is comeager for each p. We also note the following relation between the Baire Category Theorem BCT0 and 1GEN.

**Proposition 9.3.** BCT_0 ≤_sw 1GEN for Cantor space X = 2N.

*Proof.* We note that for a nowhere dense subset A we have A = ∂A = ∂A^c. Hence we obtain for every sequence (A_i) of closed nowhere dense subsets A_i ⊆ 2N

\[
\text{BCT}_0(A_i) = 2^N \setminus \bigcup_{i=0}^{\infty} A_i = \bigcap_{i=0}^{\infty} (2^N \setminus \partial A_i^c).
\]

If the sequence (A_i) is in A_c(2N) and computable from p, then there is a computable s : N → N such that A_i^c = U_i^p. Hence 1GEN(p) ⊆ BCT_0(A_i) by Lemma 9.2. This implies BCT_0 ≤_sw 1GEN. □

With Fact 4.6, Lemma 9.2 and the observation that the sets ∂U_i^p are nowhere dense, one obtains 1GEN ≤_sw BCT_0. Together with Theorem 4.3 we obtain the following.

**Corollary 9.4.** BCT_0 ≤_sw 1GEN ≤_sw BCT_2 ≤_sw BCT_0 ≤_sw lim for X = 2N.

We will sharpen this result by replacing lim with lim_1. The Turing jump operator J : N^N → N^N on Baire space N^N induces some initial topology on N^N, which we call the jump topology. This topology has been studied in [26, 8]. Moreover, we recall that lim_1 denotes the limit map lim_1 : N^N → N^N, (p_0, p_1, p_2, ...) ↦→ lim_{i→∞} p_i restricted to sequences that converge with respect to the jump topology. Hence, lim_1 is just a restriction of the ordinary limit operator lim : N^N → N^N with respect to the Baire space topology on N^N and as shown in [8] one obtains lim_1 = J^{-1} \circ \lim \circ J^N, where J^N(p_0, p_1, ...) := (J(p_0), J(p_1), ...). In [8] a point p ∈ N^N has been called limit computable in the jump, if there is a computable g ∈ N^N such that p = lim_1(g) and in [8] Proposition 9.4 it has been shown that every 1-generic limit computable p ∈ N^N is limit computable in the jump (this holds analogously for p ∈ 2N). Here we formulate a straightforward uniform version of this result.

**Proposition 9.5** (Limit computability in the jump). Let f be a multi-valued function on represented spaces that has some limit computable realizer whose range only contains 1–generic points. Then f ≤_sw lim_1.

*Proof.* Let F : N^N → N^N be a realizer of f that is limit computable and whose range only contains 1–generic points. Then there is a computable G such that F = lim_1 G. The range of G contains only sequences (p_0, p_1, p_2, ...) such that (p_i) converges to some 1–generic p and, since such a p is a point of continuity of J, the sequence (J(p_i)) converges. This means that (p_i) converges in the jump topology and hence we even obtain F = lim_1 G. This proves f ≤_sw lim_1. □
We also note the following consequence of previous results.

**Proposition 9.6** (Genericity). $\text{BCT}_0 \cap 1\text{-GEN} \equiv_{\text{sW}} \text{BCT}_0'$ and $\text{BCT}_2 \cap 1\text{-GEN} \equiv_{\text{sW}} \text{BCT}_2$ for $X = 2^N$.

**Proof.** Firstly, we note that $\text{BCT}_0 \cap 1\text{-GEN}$ is densely realized by the Baire Category Theorem \[1.2\] since the set of 1-generic points in each $p$ is comeager by Lemma \[9.4\] and in particular $\text{dom}(\text{BCT}_0 \cap 1\text{-GEN}) = \text{dom}(\text{BCT}_0') \times \text{dom}(1\text{-GEN})$. This implies $\text{BCT}_0' \leq_{\text{sW}} \text{BCT}_0 \cap 1\text{-GEN}$. With the help of Fact \[1.7\] and Lemma \[9.2\] we can conclude that $\text{BCT}_0 \cap 1\text{-GEN} \leq_{\text{sW}} \text{BCT}_0 \times \text{BCT}_0'$. Finally, Proposition \[5.5\] yields $\text{BCT}_0' \cap \text{BCT}_0 \equiv_{\text{sW}} \text{BCT}_0$. Altogether, we obtain $\text{BCT}_0 \equiv_{\text{sW}} \text{BCT}_0' \cap 1\text{-GEN}$. The proof for $\text{BCT}_2$ in place of $\text{BCT}_0'$ follows by an application of Corollary \[1.7\] in place of Fact \[1.6\].

In particular, $\text{BCT}_0 \cap 1\text{-GEN} \leq_{\text{sW}} \text{lim}$ has a realizer that is limit computable and whose range has only 1–generic points. Hence we obtain $\text{BCT}_0' \leq_{\text{sW}} \text{lim}$ by Proposition \[9.4\]. This allows us to sharpen Corollary \[9.4\] in the desired way.

**Corollary 9.7** (Genericity). $\text{BCT}_0 \leq_{\text{sW}} 1\text{-GEN} \leq_{\text{sW}} \text{BCT}_2 \equiv_{\text{sW}} \text{BCT}_0'$ and $\text{BCT}_0' \leq_{\text{sW}} 1\text{-GEN}$ and $\text{BCT}_0' \leq_{\text{sW}} \text{lim}$ for $X = 2^N$.

We obtain $\text{BCT}_0 \leq_{\text{sW}} 1\text{-GEN}$ since $\text{BCT}_0$ is computable and 1-GEN is not. We obtain $\text{BCT}_0' \leq_{\text{sW}} \text{lim}$ since $2 \leq_{\text{C}} \text{CN} \equiv_{\text{sW}} \text{lim}$ and hence $\text{lim}$ is discriminative, while $\text{BCT}_0'$ is indiscriminative by Proposition \[5.2\].

We also note the following consequence of \[12\] Theorem 14.11, which implies that any single-valued probabilistic function to Cantor space $2^N$ has to map computable inputs to computable outputs. Here a multi-valued function $f : \subseteq X \equiv Y$ on represented spaces $(X, \delta_X)$ and $(Y, \delta_Y)$ is called *probabilistic*, if there is a computable function $F : \subseteq N^\infty \times 2^N \to N^\infty$ such that $\mu(\{r \in 2^N : \delta_Y F(p, r) \in f \delta_X(p)\}) > 0$ for all $p \in \text{dom}(f \delta_X)$, where $\mu$ is the uniform measure on Cantor space $2^N$.

**Corollary 9.8.** $\text{lim}$ is not probabilistic.

We can also express consequences of our result in terms of comeager sets and for this purpose we introduce effective versions of the notion of a comeager set.

**Definition 9.9** (Comeager sets). Let $X$ be a computable Polish space. We call a subset $A \subseteq X$ *c.e. comeager* or *co-c.e. comeager* if there is a computable sequence $(A_i)$ in $\mathcal{A}_-(X)$ or $\mathcal{A}_+(X)$, respectively, such that all $A_i$ are nowhere dense and $N^\infty \setminus A = \bigcup_{i=0}^{\infty} A_i$. We add the postfix “in the limit” if the corresponding sequences are in $\mathcal{A}_-(X)'$ or $\mathcal{A}_+(X)'$, respectively.

We can now formulate the following observations.

**Corollary 9.10** (Comeager sets). Let $A, B \subseteq 2^N$.

1. $N^\infty$ is c.e. comeager, co-c.e. comeager and c.e. comeager in the limit.
2. If $A$ is c.e. comeager, then $A$ contains a dense set of computable points and all 1–generic points.
3. If $A$ is c.e. comeager in the limit, then $A$ contains a dense set of 1–generic points which are computable in the limit.
4. If $A$ is c.e. comeager, then $A$ contains a set $B$, which is co-c.e. comeager.
5. If $A$ is c.e. comeager or co-c.e. comeager, then $A$ is also c.e. comeager in the limit.
6. If $A, B$ are c.e. comeager, co-c.e. comeager or c.e. comeager in the limit, then $A \cap B$ has the respective property.
7. The set of 1–generic points is c.e. comeager in the limit.
8. The set of non-computable points is a co-c.e. comeager set.
(9) There is a co-c.e. comeager set \( A \) that only contains points which are 1-generic, in particular the set \( A \) contains no points of minimal Turing degree.

The first half of (2) follows from [5, Corollary 7], the second half follows from Lemma 9.2 (see the proof of Proposition 9.3). (3) follows from the Proposition 9.6 and Corollary 7.7 (4) follows from Corollary 4.7 noting that \( P \) can be restricted to nowhere dense sets \( A \), which satisfy \( \partial A = A \), (5) follows from Facts 3.4 and 4.6 (6) follows from the proof of Proposition 9.3 (7) follows from Lemma 9.2 and Fact 4.6 and finally Property (8) is the following example. Property (9) follows from (4) and (7) (and the well-known fact that 1-generics are not minimal). It strengthens and finally Property (8) is the following example. Property (9) follows from the proof of Proposition 5.5, (7) follows from Lemma 9.2 and Fact 4.6.

We prove that it is a co-c.e. comeager set. By \( \phi \) we denote a G"odel numbering such that the function \( \varphi_i: \mathbb{N} \to \{0, 1\} \) is the \( i \)-th computable function and by \( \Phi_i: \mathbb{N} \to \mathbb{N} \) we denote the corresponding time complexity. We define \( f_i: \mathbb{N} \to \{0, 1\} \) by

\[
f_i(t) = \begin{cases} \varphi_i(n) & \text{if } (\forall k \leq n) \Phi_i(n) \leq t \\ 0 & \text{otherwise} \end{cases}
\]

and we let

\[
A_i := \{f_i : t \in \mathbb{N}\}.
\]

Clearly, \( (A_i)_i \) is a computable sequence in \( \mathcal{A}_s(2^\mathbb{N}) \). The sequence \( (f_i)_i \) has only one cluster point \( f_i: \mathbb{N} \to \{0, 1\} \), which is \( \varphi_i \) if this function is total or otherwise it is given by

\[
f_i(n) = \begin{cases} \varphi_i(n) & \text{if } (\forall k \leq n) k \in \text{dom}(\varphi_i) \\ 0 & \text{otherwise} \end{cases}
\]

In any case \( f_i \) is a total computable function and all functions \( f_i \) are total computable too. So all members of \( A_i \) are total computable functions and if \( \varphi_i \) is total, then \( \varphi_i \in A_i \). This means that \( \bigcup_{i=0}^{\infty} A_i \) is the set of all total computable functions and \( A = 2^\mathbb{N} \setminus \bigcup_{i=0}^{\infty} A_i \) is co-c.e. comeager.

We close this section with a brief discussion of a well-known weakening of 1-genericity. By Corollary 9.10 all c.e. comeager sets contain all 1-generics. However, the class of 1-generics is not the largest class of points with this property. We recall that \( p \in 2^\mathbb{N} \) is called weakly 1-generic in \( q \in 2^\mathbb{N} \) if \( p \in U \) for each dense set \( U \subseteq 2^\mathbb{N} \) that is c.e. open in \( q \). [27, Definition 1.8.47].

Definition 9.12 (Weak 1-genericity). By 1-WGEN : \( 2^\mathbb{N} \rightharpoonup 2^\mathbb{N} \) we denote the problem

\[
1\text{-WGEN}(q) := \{p : p \text{ is weakly 1-generic in } q\}.
\]

It follows directly from this definition that every point \( p \in 2^\mathbb{N} \) which is 1-generic in \( q \) is also weakly 1-generic in \( q \). Moreover, every c.e. comeager set \( A \subseteq 2^\mathbb{N} \) contains all weakly 1-generic points. The following corollary captures the uniform content of this observation.

Corollary 9.13 (Weak 1-genericity). \( \text{BCT}_0 \leq_s \text{WGEN} \leq_s \text{1-GEN} \) for Cantor space.

10. Probabilistic Properties of the Baire Category Theorem

In this section we continue to study \( \text{BCT}_0 \) and \( \text{BCT}_2 \) on Cantor space \( X = 2^\mathbb{N} \) with respect to some probabilistic properties. In particular we will show that \( \text{BCT}_2 \leq _W \text{WWKL}' \) and \( \text{1-GEN} \leq _W \text{WWKL}' \), which yields a separation of \( \text{1-GEN} \) and \( \text{BCT}_2 \).
We recall that WWKL :⊆ Tr ⊨ 2^N denotes the problem that maps infinite binary trees T ∈ Tr to the set WWKL(T) = [T] of their infinite paths, restricted to the set of trees with positive measure, dom(WWKL) = {T ∈ Tr : µ(T) > 0}. Here µ denotes the usual uniform measure on 2^N (see [12] for more details).

By MLR(p) we denote the set of all points q ∈ 2^N that are Martin-Löf random relative to p ∈ 2^N. The Chaitin number Ω ∈ 2^N is an example of a left-c.e. Martin-Löf random point [19, Theorem 6.1.3] (where left-c.e. means that all lower rational bounds can be computably enumerated if Ω is seen as a real number in binary notation). We recall that p ∈ 2^N is called low for Ω if the Chaitin number Ω ∈ 2^N is Martin-Löf random relative to p, i.e., Ω ∈ MLR(p). This implies that the points which are low for Ω are closed downwards with respect to Turing reducibility. Since Ω is Martin-Löf random, it is clear that all computable p are low for Ω and it is well-known that the points p ∈ 2^N which are low for Ω form a meager class of points. We prove that there is even a co-c.e. comeager set A ⊆ 2^N without points that are low for Ω. The proof is inspired by the proof of [28, Theorem 3.14].

**Proposition 10.1.** There is a co-c.e. comeager set A ⊆ 2^N such that no point of A is low for Ω.

**Proof.** The Chaitin number Ω ∈ 2^N is left-c.e. and hence we can assume that we have a computable sequence (Ω_i)_i in 2^N that enumerates Ω in the sense that it converges to Ω pointwise and monotonically from below. Since Ω is computable in the limit, there is also a limit computable modulus of convergence c_Ω : N → N for the above enumeration, i.e., c_Ω(n) is the least s such that Ω_i_n = Ω_i for all t ≥ s. In particular there is a computable sequence (c_Ω,s)_s that converges to c_Ω pointwise monotonically from below.

The plan is to construct a sequence (A_i)_i of closed nowhere dense sets such that A = 2^N \ \bigcup_{n=0}^\infty A_i. By adding suitable sets A_i, we can achieve that A contains no computable points (see Example 9.11). For each p ∈ 2^N the function f :⊆ N → N with

\[ f(n) := \min\{k > n : p(k) \neq 0\}, \]

which searches the next non-zero value of p is computable in p. We now let p ∈ A. Since A contains no computable points, the function f is total. Moreover, we assume that the set A is constructed such that

\[ f(n) > c_Ω(3n) \]

holds for infinitely many n ∈ N. Let M : 2^* → R_+ be the martingale (see, e.g., [27, Definition 7.1.1] for a precise definition) defined by M(ε) := 1 and

\[ M(σb) := \begin{cases} \frac{3}{2} M(σ) & \text{if } b = Ω(σ)(|σ|) \\ \frac{1}{2} M(σ) & \text{otherwise} \end{cases} \]

for σ ∈ 2^* and b ∈ {0,1}. This martingale M is computable in f and hence in p, and we claim that M succeeds on Ω. If n is such that f(n) > c_Ω(3n), then Ω|_i_n = Ω_f(n)|_i_n. By definition M wins the round from n + 1 to 3n, i.e.,

\[ M(Ω) = \frac{3}{2} M(Ω)|_{i-1} \text{ for } i = n + 1, \ldots, 3n \]

and hence

\[ M(Ω|_{3n}) \geq \left(\frac{1}{2}\right)^n \left(\frac{3}{2}\right)^{2n} \geq \left(\frac{9}{4}\right)^n. \]

Thus \( \sup_{n \in N} M(Ω|_{i_n}) = \infty \) if \( f(n) > c_Ω(3n) \) holds for infinitely many n. This means that M succeeds on Ω and hence Ω ∉ MLR(p) by [27, Proposition 7.2.6]; thus p is not low for Ω.

We still need to construct A such that it satisfies all required conditions. We define

\[ A_i := \{p ∈ 2^N : (∀n ≥ i) p|_n ∉ f^R(3n) ⊆ p\} \]
for all $i \in \mathbb{N}$. Then $(A_i)_i$ is a computable sequence in $A_+(2^\mathbb{N})$. In order to prove this, we first note that for each fixed $n \in \mathbb{N}$
\[(\exists i)(p|_n0^{\omega_n, (3n)} \not\sqsubseteq p) \iff p|_n0^{\omega_n, (3n)} \not\sqsubseteq p\]
since $(c_{\Omega,s}(3n))_s$ converges monotone to $c_\Omega(3n)$ from below. Now we need to enumerate a sequence $(x_{ij})_j$ in $2^\mathbb{N}$ which is dense in $A_i$ and this enumeration has to be uniform in $i$: for each fixed $k$ and $n = i, \ldots, i + k$ one can generate all words $w$ that avoid all the respective blocks $0^{\omega_n, (3n)}$ of zeros for at least one $s$ (that can depend on $n$) and then one adds tails of $1$ to these words and enumerate them into $A_i$. By dovetailing one can consider all $k$, $n = i, \ldots, i + k$ and all possible $s$ for each $n$ in this way. This procedure is computable because $(c_{\Omega,s})_s$ is a computable sequence.

The sets $A_i$ are also nowhere dense since for each word $w$ of length $n = |w| \geq i$ we obtain $p \not\sqsubseteq w0^i \not\sqsubseteq A_i$. Let us suppose the contrary. Then there is a sequence $(p_k)_k$ that converges to $p$ and satisfies $p_k|_n0^{\omega_n, (3n)} \not\sqsubseteq p k$ for all $n \geq i$ and $k \in \mathbb{N}$. This implies that there is some $k_0$ such that $p|_n0^{\omega_n, (3n)} = w0^{\omega_n, (3n)} \not\sqsubseteq p k$ for all $k \geq k_0$, which is a contradiction.

For an arbitrary $p \not\sqsubseteq A_i$ there exists some $n \geq i$ such that $p|_n0^{\omega_n, (3n)} \sqsubseteq p$. This implies that $f(n) \geq n + c_\Omega(3n) \geq c_\Omega(3n)$ for some $n \geq i$, where $f(n)$ is defined.

If $p \not\sqsubseteq A = \mathbb{N} \setminus \bigcup_{i=0}^{\infty} A_i$, then $f$ is total (under the assumption that we have added additional $A_i$ that ensure that $A$ contains no computable points) and $f(n) \geq c_\Omega(3n)$ holds for infinitely many $n$, as desired.

In order to use this result to separate $\text{BCT}_2$ from $\text{WWKL}'$, we want to show that $\text{WWKL}'$ has a realizor that maps computable inputs to outputs that are low for $\Omega$. For this purpose we need a (relativized version) of the Lemma of Kučera [24, Lemma 3], which we formulate first.

**Lemma 10.2** (Kučera 1985). Let $p \in 2^\mathbb{N}$ and let $A \subseteq 2^\mathbb{N}$ be co-c.e. in $p$ with $\mu(A) > 0$. Then for any $q \in \text{MLR}(p)$ there exist $w \in 2^*$ and $r \in A$ such that $q = wr$.

The standard proof of the Lemma of Kučera relativizes directly to the formulation given above (see for instance the proof of [19, Lemma 6.10.1]). This leads to the following observation (see also [1, Theorem 3.7] for an account of the situation for 2-randomness in reverse mathematics). We recall that a point $p \in 2^\mathbb{N}$ is called $(n + 1)$–random for $n \in \mathbb{N}$, if $p \in \text{MLR}(\emptyset^{(n)})$.

**Proposition 10.3**. Let $n \in \mathbb{N}$. Then $\text{WWKL}^{(n)}$ has a realizor that maps computable inputs to outputs that are Turing below any fixed $(n + 1)$–random. If $n \geq 1$ then the outputs are in particular low for $\Omega$.

**Proof.** Let $p = \hat{0}$ be the constant zero sequence. Fix $n \geq 1$ and let $q \in \text{MLR}(p^{(n)})$ be some $(n + 1)$–random point. The computable inputs of $\text{WWKL}^{(n)}$ are exactly those binary trees $T$ such that the sets $A = [T] \subseteq 2^\mathbb{N}$ are of positive measure and co-c.e. in $p^{(n)}$. By Lemma 10.2 for every such set $A \subseteq 2^\mathbb{N}$ there exists some $r \in A$ and $w \in 2^*$ such that $q = wr$. In particular $r \leq_T q$. This means that $\text{WWKL}^{(n)}$ has a realizor $F$ that maps computable inputs to outputs that are Turing below the $(n + 1)$–random $q$. Since $q \in 2^\mathbb{N}$ is 2–random if and only if it is Martin-Löf random and low for $\Omega$ [27, Proposition 3.6.19] and the class of points which are low for $\Omega$ is downwards closed with respect to Turing reducibility, it follows that $F$ maps computable inputs to outputs that are low for $\Omega$, if $n \geq 1$.

If we combine Propositions 10.1 and 10.3 then we obtain the following conclusion.

**Theorem 10.4.** $\text{BCT}_2 \not\leq_W \text{WWKL}^{(n)}$ for all $n \in \mathbb{N}$. 
Proof. Let us assume that $\text{BCT}_2 \leq_w \text{WWKL}^{(n+1)}$ for some $n \in \mathbb{N}$. Then there are computable $H, K$ such that $H(\langle d, GK \rangle)$ is a realizer of $\text{BCT}_2$ whenever $G$ is a realizer of $\text{WWKL}^{(n+1)}$. By Proposition 10.3 there is a co-c.e. comeager set $A = \mathbb{N}^2 \cup \bigcup_{i=0}^{n} A_i$ that contains no point $r \in A$ that is low for $\Omega$ and such that $(A_i)_i$ is a computable input for $\text{BCT}_2$ with $A = \text{BCT}_2((A_i)_i)$. Hence there is a computable name $p$ of $(A_i)_i$ such that $K(p)$ is a computable name for some input of $\text{WWKL}^{(n+1)}$. By Proposition 10.3 there exists a realizer $G$ of $\text{WWKL}^{(n+1)}$ that maps this computable input $K(p)$ to an output $q = G(p)$ which is low for $\Omega$. Hence $r = H(p, q) \leq_T q$ is also low for $\Omega$ and $r \in A$, which is a contradiction. Since $\text{BCT}_2 \not\leq_w \text{WWKL}$ and $\text{WWKL} \leq_w \text{WWKL}'$, it follows that also $\text{BCT}_2 \not\leq_w \text{WWKL}$.

This yields the following obvious question.

Question 10.5. Is $\text{BCT}_2$ probabilistic?

$\text{BCT}_0 \leq_w \text{WWKL}^{(n)}$ would imply $\text{BCT}_2 \leq_w \text{BCT}'_0 \leq_w \text{WWKL}^{(n+1)}$ by Proposition 5.5 which contradicts Theorem 10.4. Hence we also obtain the following corollary.

Corollary 10.6. $\text{BCT}_0 \not\leq_w \text{WWKL}^{(n)}$ for all $n \in \mathbb{N}$.

In the next step we want to provide some probabilistic upper bound for $1\text{-}\text{GEN}$. For this purpose we need $(1 - \ast)\text{-WWKL}'$, where

$$(1 - \ast)\text{-WWKL}(T_n) = \bigcup_{n=0}^{\infty} (1 - 2^{-n})\text{-WWKL}(T_n)$$

was introduced in [12] and is based on $\varepsilon - \text{WWKL}(T)$, which is $\text{WWKL}$ restricted to $\text{dom}(\varepsilon\text{-WWKL}) = \{ T : \mu(\{j \in \mathbb{N}^n : T_j \neq T_n \}) > \varepsilon \}$ for every $\varepsilon \in [0, 1]$ (this problem was first introduced in [13]).

Intuitively speaking, $(1 - \ast)\text{-WWKL}$ is the problem that, given a sequence of trees $(T_n)$ with $\mu(\{T_n \}) > 1 - 2^{-n}$ finds an infinite path $p \in T_n$ in one of these trees together with the information $n$ that indicates which tree it is.

A classical Theorem of Kurtz [25] states that every $2$-random degree bounds a 1-generic degree. Using the fireworks argument we prove the following result, which can be seen as a uniform version of the Theorem of Kurtz. Alternatively, one could approach this result using the technique recently introduced by Barmpalias, Day and Lewis-Pye [2].

Theorem 10.7 (Uniform Theorem of Kurtz). $1\text{-}\text{GEN} \leq_w (1 - \ast)\text{-WWKL}'$.

Proof. Given a $q \in 2^\mathbb{N}$ we want to find some $p \in 2^\mathbb{N}$ that is 1-generic relative to $q$ with the help of $(1 - \ast)\text{-WWKL}'$. We describe a probabilistic algorithm that computes such a $p$ with probability greater than $1 - 2^{-k}$ from a given $q \in 2^\mathbb{N}$ and $k \in \mathbb{N}$. Let $(U^n_i)_i$ be an enumeration of c.e. open sets relative to $q$; we can assume that each $U^n_i$ has the form $U^n_i = \bigcup_{j=0}^{\infty} w_{ij}2^\mathbb{N}$ with words $w_{ij} \in \{0, 1\}^*$. The goal is to satisfy the property $R_i : p \not\in \partial U^n_i$ for all $i \in \mathbb{N}$, which can be reformulated as

$$R_i : \exists j \ w_{ij} \subseteq p$$

This can be achieved by a probabilistic algorithm that uses another “random” input $r \in 2^\mathbb{N}$ which we consider as a sequence $r = n_0 q_1 n_2 \ldots$ of blocks $n_i \in \{0, 1\}^*$ of length $|n_i| = k + i + 1$. Each such block $n_i$ is identified with a number $n_i \in \{1, \ldots, 2^{k+i+1}\}$.

Algorithm. Upon input of $q, r$ and $k$ the probabilistic algorithm works in steps $s = 0, 1, 2, \ldots$, and computes a sequence $p$ by producing longer and longer prefixes $v_s$ of $p$. Initially the prefix $v_0$ is the empty sequence. We also use two sequences

\[\text{The fireworks technique is due to Andrei Rumyantsev and Alexander Shen [31]; the fact that it can be used to prove that every 2-random degree bounds a 1-generic has been communicated to us by Laurent Bienvenu; see also [3].}\]
of natural number programming variables \((c_i)\) and \((l_i)\), which are initially all set to zero. In stage \(s = (i, j)\) we perform the following steps, provided \(R_s\) has not yet been declared as satisfied (otherwise we do nothing):

1. If \(w_{ij} \subseteq v_s\), then property \(R_s\) is declared as satisfied and we set \(v_{s+1} := v_s\).
2. If \(v_s \subseteq w_{ij}\), then we set \(v_{s+1} := w_{ij}\) and property \(R_s\) is declared as satisfied.
3. If \(v_s\) is incompatible with \(w_{ij}\), but has a common prefix with it of length greater or equal to \(l_i\), then we consider this as an “event” and we do the following:
   
   (a) We increase the “event counter” \(c_i := c_i + 1\) and we set the “length bound” to \(l_i := |v_s|\).
   
   (b) If \(c_i = n_i\), then we consider this as a “critical event” and we increase \(j\) step by step until we find some \(j\) with \(v_s \subseteq w_{ij}\) in which case we set \(v_{s+1} := w_{ij}\) and property \(R_s\) is declared as satisfied (if no suitable \(j\) is found, then the algorithm loops here forever).

**Verification.** We note that the algorithm produces an infinite output \(p = \sup_s v_s\) if it never happens to loop forever in case of a critical event in Step (3)(b).

In this case all properties \(R_s\) are satisfied, either because there is some \(j\) with \(w_{ij} \subseteq p\) (in which case \(R_s\) will be declared to be satisfied) or because the event counter \(c_i\) never reaches the critical value \(n_i\), which means that there exists some \(w \subseteq p\) such that \(w\) is incompatible with \(w_{ij}\) for all \(j\).

**Success probability.** The algorithm is unsuccessful if and only if there is an \(i\) such that an infinite loop in Step (3)(b) occurs. We need to calculate the probability that this happens for some arbitrary \(r \in 2^N\) (seen as a sequence \((n_i)_i\)).

The key observation for this calculation is to understand what counts as an “event”: whenever an event happens and \(c_i\) is increased, then the next event will happen only if there is a \(w_{ij}\) that extends the current output \(v_s\). The unsuccessful case happens if the event counter reaches \(c_i = n_i\) for some \(i\) and an infinite loop is reached since no suitable \(j\) is found afterwards in Step (3)(b). Let us fix such an \(i\) and the corresponding \(n_i\) that leads to an infinite loop. Then we claim that no other value of \(n_i \in \{1,...,2^{k+i+1}\}\) can lead to an infinite loop:

1. Since the event counter eventually reached the value \(c_i = n_i\) no infinite loop can happen in Step (3)(b) for a smaller value of \(n_i\) due to the key observation above.
2. Since Step (3)(b) enters an infinite loop for the current value of \(n_i\), the event counter could never reach a larger value of \(n_i\) due to the key observation above.

Since at most one value \(n_i \in \{1,...,2^{k+i+1}\}\) can lead to an infinite loop, the failure probability for our fixed \(i\) and \(n_i\) is \(\leq 2^{-k-i-1}\) and hence the total failure probability for \(r\) is \(\leq \sum_{i=0}^{\infty} 2^{-k-i-1} = 2^{-k}\). So the probability that the “random input” \(r\) is successful is \(\geq 1 - 2^{-k}\).

This probabilistic algorithm describes a computable function \(H\) that computes \(p = H(q, \langle k, r \rangle)\), given \(q, r \in 2^N\) and \(k \in \mathbb{N}\).

We still need to describe a computable function \(K\) that given \(q\) and \(k\) computes a name for a sequence \((T_m)_{m}\) of binary trees that converges to some binary tree \(T = \lim_{m \to \infty} T_m\) such that \([T]\) is the set of successful random advices \(r \in 2^N\).

For this purpose, we let \(T_m\) initially be the full binary tree of all paths of length \(h_m = \sum_{i=0}^{m} 2^{k+i+1}\) (i.e., all the paths \(v \in T_m\) contain suitable values \(n_0, ..., n_m\)).

Then we simulate the above algorithm for input \(q, k\) and each path \(v \in T_m\) of full length \(h_m\), as a prefix of \(r\) for all stages \(s = (i, j) \leq m\). This bound implies \(i \leq m\) and hence the simulation will never require an \(n_i\) which is not included in \(v\). If the algorithm runs through without ever entering a search for \(j\) in some Step (3)(b) that runs longer than for \(m\) values of \(j\), then \(v\) is kept in the tree \(T_m\), otherwise \(v\) is
shortened to length $h_s$ for the corresponding stage $s$ at which the problem occurred. If a random advice $r \in 2^N$ is successful, then each critical search that it enters in some Step (3)(b) will terminate after finitely many steps, hence longer and longer prefixes of $r$ will be included in the sequence $(T_m)_m$ and so $r \in \lim_{m \to \infty} T_m$. On the other hand, if $r \in \lim_{m \to \infty} T_m$, then each critical Step (3)(b) will eventually terminate for $r$. Thus $T := \lim_{m \to \infty} T_m$ is a tree such that $[T]$ contains exactly the successful $r \in 2^N$.

Thus the desired reduction $1\text{-GEN} \leq_W (1 - \ast)\text{-WWKL}'$ is given by the computable functions $H, K$; more precisely, $q \mapsto H(q, G(K(q, 0), K(q, 1), ...))$ is a realizer of $1\text{-GEN}$ whenever $G$ is a realizer of $(1 - \ast)\text{-WWKL}'$. $\square$

We note that Corollaries 9.7 and 10.6 show that the reduction in Theorem 10.7 cannot be improved to a strong one. Theorem 10.7 yields

$$1\text{-GEN} \leq_W (1 - \ast)\text{-WWKL}' \leq_s \text{WWKL}^\prime$$

and hence we obtain the following corollary with the help of Theorem 10.4.

**Corollary 10.8.** $\text{BCT}_2 \not\leq_s 1\text{-GEN}$. Since $\text{BCT}_0 \leq_s 1\text{-GEN}$ by Corollary 9.7, we also obtain the following consequence of Theorem 10.7 and Corollary 10.6.

**Corollary 10.9.** $1\text{-GEN} \not\leq_s \text{WWKL}^{(n)}$ for all $n \in \mathbb{N}$. We can easily derive probabilistic upper bounds for $\text{BCT}_1$ and $\text{BCT}_3$. For one, $\text{BCT}_1 \equiv_s \text{C}_N \text{PC}_{\mathbb{N} \times 2^N} \leq_s \text{WWKL}^\prime$ by [12, Theorem 9.3] and by Fact 1.4 and hence $\text{BCT}_3 \leq_s \text{BCT}_1 \leq_s \text{WWKL}^{\ast}$ by Proposition 3.5.

**Corollary 10.10.** $\text{BCT}_1 \leq_s \text{WWKL}^\prime$ and $\text{BCT}_3 \leq_s \text{WWKL}^{\ast}$ for any fixed computable Polish space $X$.

11. Conclusion

The diagram in Figure 1 shows different versions of the Baire Category Theorem for computable perfect Polish spaces in the Weihrauch lattice together with their neighborhood. The solid lines indicate strong Weihrauch reductions against the direction of the arrow and the dashed lines indicate ordinary Weihrauch reductions.
