INFINITE CW-COMPLEXES, BRAUER GROUPS AND PHANTOM COHOMOLOGY

JENS HORNBOSTEL AND STEFAN SCHRÖER

Abstract.
Expanding a result of Serre on finite CW-complexes, we show that the Brauer group coincides with the cohomological Brauer group for arbitrary compact spaces. Using results from the homotopy theory of classifying spaces for Lie groups, we give another proof of the result of Antieau and Williams that equality does not hold for Eilenberg–MacLane spaces of type $K(\mathbb{Z}/n\mathbb{Z}, 2)$. Employing a result of Dwyer and Zabrodsky, we show the same for the classifying spaces $BG$ where $G$ is an infinite-dimensional $\mathbb{F}_p$-vector space. In this context, we also give a formula expressing phantom cohomology in terms of homology.

Introduction

Generalizing and unifying classical constructions, Grothendieck [21] introduced the Brauer group $\text{Br}(X)$ and the cohomological Brauer group $\text{Br}'(X)$ for arbitrary ringed spaces and ringed topoi. Roughly speaking, the elements in the former are equivalence classes of geometric objects, which can be regarded, among other things, as $\text{PGL}_n$-bundles. In contrast, elements in the latter are cohomology classes in degree two of finite order, with coefficients in the multiplicative sheaf $\mathcal{O}_X^\times$ of units in the structure sheaf. The machinery of nonabelian cohomology yields an inclusion

$$\text{Br}(X) \subset \text{Br}'(X),$$

and Grothendieck raised the question under which circumstances this inclusion is an equality. This question is particularly challenging in algebraic geometry, where one works with the étale site of a scheme $X$. According to an unpublished result of Gabber, for which de Jong [10] gave an independent proof, equality $\text{Br}(X) = \text{Br}'(X)$ holds for quasiprojective schemes. For many schemes, for example smooth

2010 Mathematics Subject Classification. 55N10, 16K50, 14F22.
threefolds without ample sheaves, the question is regarded as wide open. Note that there are ”trivial” counterexamples based on nonseparated schemes ([12], Corollary 3.11) and that equality holds for normal algebraic surfaces [41] and smooth complex surfaces [42].

The goal of this paper is to study Grothendieck’s question in a purely topological settings, where $X$ is a CW-complex, endowed with the sheaf of continuous complex-valued functions. In this situation, the cohomological Brauer group $\text{Br}'(X)$ can be identified with the torsion part of $\text{Ext}^1(H_2(X)/\text{Divisible}, \mathbb{Z})$.

According to a result of Serre outlined in [21], equality $\text{Br}(X) = \text{Br}'(X)$ holds for finite CW-complexes. Slightly expanding Serre’s result, we show:

**Theorem.** For each compact space $X$, we have $\text{Br}(X) = \text{Br}'(X)$.

A construction of Bödigheimer [6] involving “long spheres” then implies that for any torsion group $T$, there is indeed a compact space—usually not admitting a CW-structure—whose Brauer group is $T$.

The main part of this paper, however, is concerned with infinite CW-complexes. Then equality between Brauer group and cohomological Brauer group does not necessarily hold:

**Theorem (Antieau and Williams).** Let $X$ be an Eilenberg–MacLane space of type $K(\mathbb{Z}/n\mathbb{Z}, 2)$. Then the the Brauer group $\text{Br}(X)$ vanishes, whereas the cohomological Brauer group $\text{Br}'(X)$ is cyclic of order $n$.

Antieau and Williams [1] used multiplicative properties of the cohomology ring $H^*(\text{PU}(n), \mathbb{Z})$ with respect to the torsion subgroup. The case $n = 2$ was already considered by Atiyah and Segal [4]. Unaware of these results, we had found another proof; after putting the first version of this paper onto the arXiv, Antieau and Williams informed us about [1].

Our approach is based on a fact from the homotopy theory of classifying spaces of connected simple Lie groups, stating that any self map $BG \to BG$ not homotopic to a constant map induces bijections on rational homology groups. Nontrivial homotopy classes of selfmaps indeed exists, namely the *unstable Adams operations* $\psi^k$ first constructed by Sullivan [46], and further studied by Ishiguro [27], Notbohm [37], and Jackowski, McClure and Olivier [28].

We also show for arbitrary abelian groups $G$, any Brauer class on the Eilenberg–MacLane space of type $K(G, 2)$ must live in the torsion part of $\text{Ext}^1(G/\text{Torsion}, \mathbb{Z})$, and such classes vanish on all compact subsets (“phantom classes”). The latter is a special case of the following purely algebraic description of such phantoms, a kind of Universal Coefficient Theorem, which might be useful in other contexts:

**Theorem.** Let $X$ be a CW-complex and $n \geq 0$. Then the subgroup $\text{Ext}^1(H_{n-1}(X)/\text{Torsion}, \mathbb{Z}) \subset H^n(X)$ comprises precisely those cohomology classes that vanish on all finite subcomplexes.

It is easy to see that the cohomological Brauer group for Eilenberg–MacLane spaces of type $K(G, n)$, $n \geq 3$ vanishes. We finally analyze the case $n = 1$, that is, classifying spaces $BG = K(G, 1)$ for arbitrary discrete groups $G$. According to result of Kan and Thurston [30], every CW-complex is homotopy equivalent
to the *plus construction* \((BG)^+\) for some group \(G\), which is usually uncountable, with respect to some perfect normal subgroup \(N \subset G\). In some sense, this reduces Grothendieck’s question on the equality of \(\text{Br}(X) \subset \text{Br}'(X)\) to the case \(X = BG\). Our third main result is:

**Theorem.** Let \(X = BG\) be the classifying space of an infinite-dimensional \(\mathbb{F}_p\)-vector space \(G\). Then \(\text{Br}(X) \subset \text{Br}'(X)\).

The proof relies on a result of Dwyer and Zabrodsky [11], who showed that every bundle over the classifying space of finite \(p\)-groups comes from a representation, together with some facts on unitary representations due to Backhouse and Bradley [5]. We actually prove a more general version, where \(G\) can be a \(p\)-primary torsion group whose basic subgroups \(H \subset G\) are infinite.

The paper is organized as follows: In Section 1 we recall some well-known facts on Brauer groups in the topological context and show that \(\text{Br}(X) = \text{Br}'(X)\) holds for compact spaces. In Section 2 we give further preparatory material. Section 3 contains a new proof that the Brauer group of an Eilenberg–MacLane space of type \(K(\mathbb{Z}/n\mathbb{Z}, 2)\) vanishes, a discussion of Brauer groups for general \(K(G, 2)\) and a Universal Coefficient Theorem for “phantom” cohomology classes. In the final Section 4 we turn to classifying spaces \(BG = K(G, 1)\) for discrete groups. Here the main result is that for many infinite \(p\)-primary torsion groups, for example infinite-dimensional \(\mathbb{F}_p\)-vector spaces, the Brauer group of \(BG\) is strictly smaller than the cohomological Brauer group.

**Acknowledgement.** We wish to thank Benjamin Antieau and Ben Williams for informing us about the papers [1], [2] and [49], and the referees for suggestions, which helped to improve the paper. The second author wishes to thank Wilhelm Singhof for useful discussions.

1. **Recollecton: Topological Brauer Groups**

In this section we recall and collect some useful facts on Brauer groups of topological spaces, most of which are well-known. Throughout, we shall encounter both sheaf and singular cohomology; if not indicated otherwise, cohomology groups are sheaf cohomology groups.

First suppose \(X\) is a general ringed topos. We write \(\text{PGL}_n(O_X)\) for the sheaf of groups associated to the presheaf \(U \mapsto \text{PGL}_n(\Gamma(U, O_X))\). As explained in [21], Section 1, the obstruction for extending a \(\text{PGL}_n(O_X)\)-torsor \(T\) to a \(\text{GL}_n(O_X)\)-torsor is a cohomology class \(\alpha \in H^2(X, O_X^\times)\). More precisely, one has an exact sequence

\[
H^1(X, O_X^\times) \longrightarrow H^1(X, \text{GL}_n(O_X)) \longrightarrow H^1(X, \text{PGL}_n(O_X)) \longrightarrow H^2(X, O_X^\times)
\]

of pointed sets coming from the theory of nonabelian cohomology (compare [19], Chapter V and [13], Chapter I, §5). We say that \(\alpha\) is the *obstruction class* of the torsor \(T\); it might also be regarded as a *characteristic class*. Similarly, the obstruction against extending \(T\) to an \(\text{SL}_n(O_X)\)-torsor is a class \(\dot{\alpha} \in H^2(X, \mu_n(O_X))\), which maps to \(\alpha\), revealing that \(n \cdot \alpha = 0\). Following Grothendieck, we regard the *cohomological Brauer group* \(\text{Br}'(X)\) as the torsion part of \(H^2(X, O_X^\times)\). In contrast, the *Brauer group*

\[
\text{Br}(X) \subset \text{Br}'(X) \subset H^2(X, O_X^\times)
\]
is the subset of elements that are obstruction classes for some $\text{PGL}_n(\mathcal{O}_X)$-torsors $\mathcal{T}$ for certain $n \geq 1$.

Another way to see this goes as follows: The $\alpha \in H^2(X, \mathcal{O}_X^\times)$ correspond to isomorphism classes of $\mathcal{O}_X^\times$-gerbes $\mathcal{X}$ over $X$, and $\alpha$ lies in the Brauer group if one may choose $\mathcal{X}$ as the gerbe of extensions to $\text{GL}_n(\mathcal{O}_X)$-torsors for some $\text{PGL}_n(\mathcal{O}_X)$-torsor $\mathcal{T}$ (see [15], Chapter V, §4). As explained in [10], this is equivalent to the existence of certain locally free twisted sheaf of rank $n$, where the twisting is with respect to some cocycle representing $\alpha$.

Now let $X$ be a topological space, and assume that the structure sheaf $\mathcal{O}_X$ is the sheaf of continuous complex-valued functions $C_X$. The exponential sequence

$$0 \to \mathbb{Z} \to C_X \to C_X^\times \to 1,$$

yields an exact sequence

$$H^2(X, C_X) \to H^2(X, C_X^\times) \to H^3(X, \mathbb{Z}) \to H^3(X, C_X).$$

Recall that a space $X$ is paracompact if it is Hausdorff, and every open covering admits a refinement that is locally finite. For paracompact spaces, the sheaf $C_X$ is soft by the Uryson Lemma, whence acyclic (see [17], Chapter II, Theorem 4.4.3), thus one has a canonical identification of $\text{Br}'(X)$ with the torsion part of $H^3(X, \mathbb{Z})$.

Throughout, we are mainly interested in CW-complexes. Then there is a useful interpretation in terms of singular homology groups as well. For any abelian group $G$, let us write

$$\text{Torsion} G \quad \text{and} \quad G/\text{Divisible}$$

for the torsion subgroup, and the quotient by the maximal divisible subgroup, respectively.

**Proposition 1.1.** If $X$ is a CW-complex, then there is a canonical identification

$$\text{Br}'(X) = \text{Torsion Ext}^1(H_2(X), \mathbb{Z}),$$

and this equals the torsion part of $\text{Ext}^1(H_2(X)/\text{Divisible}, \mathbb{Z})$ as well.

**Proof.** The first assertion is well-known, and relies on the fact that CW-complexes are paracompact (Miyazaki’s result, see [14], Theorem 1.3.5), that sheaf cohomology for the sheaf of locally constant integer-valued functions coincides with singular cohomology (compare [7], Chapter III, Section 1), and the Universal Coefficient Theorem.

From this the second assertion easily follows: let $D \subset H_2(X)$ be the maximal divisible subgroup. Since divisible groups are injective objects, this is a direct summand, and it remains to check that $\text{Ext}^1(D, \mathbb{Z})$ is torsion free. Now any divisible group is a direct sum of groups of the form $\mathbb{Q}$ and $\mathbb{Z}[p^{-1}]/\mathbb{Z}$. But $\text{Ext}^1(\mathbb{Q}, \mathbb{Z})$ is a $\mathbb{Q}$-vector space (in fact, of dimension $2^{|\mathbb{Q}|}$, compare [50]), and $\text{Ext}^1(\mathbb{Z}[p^{-1}]/\mathbb{Z}, \mathbb{Z})$ is isomorphic to the group of $p$-adic integers $\mathbb{Z}_p$ (see [47], p. 74).

Let us record the following immediate consequence:

**Corollary 1.2.** Let $X$ be a CW-complex such that $H_2(X)$ is a direct sum of a divisible group and a free abelian group. Then $\text{Br}'(X) = 0$.

For a characterization of abelian groups $G$ with torsion free $\text{Ext}^1(G, \mathbb{Z})$, we refer to [33], Theorem 2.13. Under suitable set theoretical assumptions, this is precisely the sums of divisible and free groups [34].
Concerning the Brauer group, one can say the following. First observe that the sheaf of groups $\text{PGL}_n(\mathbb{C}_X)$ may be regarded as the sheaf of continuous $\text{PGL}_n$-valued functions. By abuse of notation, we write $\text{PGL}_n$ for the Lie group $\text{PGL}_n(\mathbb{C})$ of $n \times n$ invertible matrices modulo scalar matrices. There is a well-known equivalence of categories between the category of locally trivial principal $\text{PGL}_n$-bundles $P \to X$ and the category of $\text{PGL}_n(\mathbb{C}_X)$-torsors $T$, sending $P$ to the sheaf of sections $T$ (compare [19], Proposition 5.1.1).

In practice, it is sometimes convenient to work with more geometric objects instead. Let $f : V \to X$ be a continuous map whose fibers $f^{-1}(x), x \in X$ are homeomorphic to $\mathbb{C}P^{n-1}$. A chart $(U, \psi)$ consists of an open subset $U \subset X$ and an $U$-homeomorphism $\psi : f^{-1}(U) \to \mathbb{C}P^{n-1} \times U$. Two charts $(U, \psi)$ and $(U', \psi')$ are compatible if the transition maps $\psi' \circ \psi^{-1}$ take values in $\text{PGL}_n$ fiberwise over $U \cap U'$. An atlas is a collection of compatible charts $(U_i, \psi_i)$ with $X = \bigcup_i U_i$. A $\mathbb{C}P^{n-1}$-bundle in a continuous map $f : V \to X$ as above, endowed with a maximal atlas. One may also view them also as relative Brauer–Severi-varieties over $X$ in the sense of Hakim [22]. We have an equivalence of categories between the category of locally principal $\text{PGL}_n$-bundles $P \to X$ and the category of $\mathbb{C}P^{n-1}$-bundles $V \to X$, sending the locally trivial principal bundle $P$ to the associated locally trivial fiber bundle $V$ defined as the quotient of $\mathbb{C}P^{n-1} \times P$ by the diagonal left action of $\text{PGL}_n$ (compare [26], Chapter 4).

Throughout, we shall write $H^1(X, \text{PGL}_n)$ for the set of isomorphism classes of objects $T$, $P$, $V$ in their respective categories. We simply use the term $\text{PGL}_n$-bundle, or just projective bundle when it is clear from the context to which objects we refer. The operation $\text{PGL}_m \times \text{PGL}_n \to \text{PGL}_{mn}$ that comes from tensor product of matrices induces a pairing

$$H^1(X, \text{PGL}_m) \times H^1(X, \text{PGL}_n) \to H^1(X, \text{PGL}_{mn}),$$

which in turn gives the addition in the Brauer group. We shall write $P \otimes P'$ and $V \otimes V'$ for the corresponding operations on bundles, respectively.

Stabilizing with respect to tensor products with trivial bundles leads to the colimit $\text{PGL} = \text{PGL}_\infty$. Note that this stabilization is different from the stabilization for vector resp. $\text{GL}_n$-bundles denoted by $\text{GL} = \text{GL}_\infty$ and given by adding trivial bundles. These different stabilizations are the reason why $\pi_{2k}(\text{BPGL}) \cong \mathbb{Q}$ is different from $\pi_{2k}(\text{BGL}) \cong \pi_{2k}(\text{BU}) \cong \mathbb{Z}$ for all $k \geq 1$ even if $\pi_{2k}(\text{BPGL}_n) \cong \pi_{2k}(\text{BGL}_n) \cong \pi_{2k}(\text{BU}(n))$. Finally, note that tensoring a bundle with a trivial bundle does not change its obstruction class.

Given a topological group $G$ admitting a CW-structure, we denote by $BG$ the classifying space for numerable principal $G$-bundles. We regard it as a connected CW-complex homotopy equivalent to the Milnor’s join construction $G \star G \star \ldots$, together with a universal bundle, and write $[X, BG]$ for the pointed set of homotopy classes of continuous maps.

We are mainly interested in the case $G = \text{PGL}_n$ and $G = \text{PU}(n)$. The latter is the quotient of the unitary group $U(n)$ by the diagonally embedded circle group $U(1) = S^1$, which is also the quotient of the special unitary group $\text{SU}(n)$ by the diagonally embedded group of $n$-th roots of unity $\mu_n = \mu_n(\mathbb{C})$. For paracompact spaces $X$ all locally trivial principal bundles are numerable, thus

$$H^1(X, \text{PGL}_n) = [X, \text{BPGL}_n] = [X, \text{BPU}(n)],$$

the latter because $\text{BPU}(n) \to \text{BPGL}_n$ is a homotopy equivalence.
Remark 1.3. Some non-numerable locally trivial principal bundles over non-paracompact Hausdorff spaces are described in [8] and [43].

Let us record the following fact, which is essentially Serre’s result on the Brauer group of finite CW-complexes:

**Theorem 1.4.** Let $X$ be a compact space. Then $Br(X) = Br'(X)$.

**Proof.** Let $\alpha \in Br'(X) \subset H^3(X, \mathbb{Z})$ be a cohomology class, say of order $n \geq 1$. Choose a lift $\tilde{\alpha} \in H^2(X, \mathbb{Z}/n\mathbb{Z})$. On paracompact spaces, sheaf cohomology coincides with Čech cohomology, according to [17], Chapter II, Theorem 5.10.1. Moreover, Čech cohomology on paracompact spaces with countable coefficients can be described via homotopy classes of continuous maps into Eilenberg–MacLane spaces, according to P. Huber’s result [24]. Let $Y$ be an Eilenberg–MacLane space of type $K(\mathbb{Z}/n\mathbb{Z}, 2)$, and $f : X \to Y$ a continuous map representing $\tilde{\alpha}$. The image $f(X) \subset Y$ is compact, whence contained in a finite subcomplex $Y' \subset Y$. By Serre’s result [21], Theorem 1.6, the restriction of the universal cohomology class to $Y'$ is the obstruction of some projective bundle $V' \to Y'$, and the pullback $f^*(V')$ shows that $\alpha$ lies in the Brauer group. \hfill \Box

From this we get an amusing existence result:

**Corollary 1.5.** For every abelian torsion group $T$, there is a compact space $X$ so that $Br(X)$ is isomorphic to $T$ and that the inclusion $Br(X) \subset Br'(X) \subset H^3(X, \mathbb{Z})$ are equalities.

**Proof.** Using “long spheres”, Bödigheimer [6] constructed compact spaces realizing preassigned Čech cohomology groups. In particular, there is a compact space $X$ with $H^3(X, \mathbb{Z}) \cong T$. But on paracompact spaces, Čech cohomology coincides with sheaf cohomology, by [17], Chapter II, Theorem 5.10.1, and the result follows. \hfill \Box

Note that for infinite abelian torsion groups $T$, there can be no CW structure on $X$. For otherwise there are only finitely many cells by compactness, and $H^3(X)$ would be finitely generated by the cellular cochain complex.

## 2. Some infinite CW-complexes

We start by constructing a concrete projective bundle on a particular CW-complex $Y$ of dimension three. Fix some $n \geq 1$, and let $Y$ be the space obtained by attaching a 3-cell to the 2-sphere along a continuous map $\varphi : S^2 \to S^2$ of degree $n$. We thus have a cocartesian diagram

\[
\begin{array}{ccc}
S^2 & \longrightarrow & D^3 \\
\varphi \downarrow & & \downarrow \Phi \\
S^2 & \longrightarrow & Y
\end{array}
\]

and regard $Y = e^0 \cup e^2 \cup e^3$ as a CW-complex with three cells. The cellular cochain complex (see for example [48], Chapter II, Theorem 2.19), or the cellular chain complex together with the Universal Coefficient Theorem easily yields

$$Br'(Y) = \text{Torsion } H^3(Y) = H^3(Y) = \mathbb{Z}/n\mathbb{Z}.$$  

By Serre’s result, this group is generated by some $\text{PGL}_n'$-bundle. The following argument shows that one may actually choose $n' = n$:
Let \( L \) be a complex line bundle on the 2-skeleton \( Y^2 = S^2 \) with Chern class \( c_1(L) = 1 \) (that is, the tautological bundle on \( \mathbb{CP}^1 \)), where the Chern class is regarded as element of \( H^2(S^2) = \mathbb{Z} \), and consider the complex vector bundle \( E = L \oplus \mathbb{C}^{n-1} \) of rank \( n \). Then
\[
\varphi^*(L \oplus \mathbb{C}^{n-1}) = L^\otimes n \oplus \mathbb{C}^{n-1}.
\]
Although the classifying map \( Y^2 \to B\text{GL}_n \) for \( E \) does not extend to \( Y \), we have \( L^\otimes n \oplus \mathbb{C}^{n-1} \cong L \oplus \ldots \oplus L \). This is because vector bundles of rank \( n \) on the 2-sphere correspond, up to isomorphism, to elements in \( \pi_1(\text{GL}_n) \), the bundles in question have isomorphic determinant, and the determinant map \( \text{GL}_n \to \mathbb{C}^* \) induces a bijection on fundamental groups. Since the projectivization of \( L \oplus \ldots \oplus L \) is isomorphic to the product bundle \( \mathbb{CP}^{n-1} \times S^2 \), the classifying map \( Y^2 \to B\text{PGL}_n \) extends to \( Y \), which yields a \( \text{PGL}_n \)-bundle \( V \to Y \).

**Proposition 2.1.** The obstruction class of the projective bundle \( V \to Y \) constructed above generates the group \( \text{Br}'(Y) \).

*Proof.* Fix \( 0 < i < n \). Since \( \text{Br}'(Y) \) is cyclic of order \( n \), it suffices to check that \( V^\otimes i \) is not the projectivization of a vector bundle. Suppose to the contrary that it is the projectivization of a vector bundle \( E \to Y \). Obviously, it has rank \( in \), and \( \varphi^*(E) \) is trivial. In light of the exact sequence of pointed sets (1) applied to \( X = Y^2 \), we have \( E|Y^2 \cong (L \oplus \mathbb{C}^{n-1})^\otimes i \otimes N \) for some line bundle \( N \to Y^2 \). Consequently
\[
\varphi^*(E) = (L^\otimes n \oplus \mathbb{C}^{n-1})^\otimes i \otimes N^\otimes n.
\]
Taking first Chern classes, we obtain \( 0 = c_1 \varphi^*(E) = in^i + in^{i+1}c_1(N) \), thus \( n|i \), contradiction. \( \Box \)

The following seems to be well-known, but we could not find a reference for it. One can also deduce it from the preceding construction:

**Proposition 2.2.** Let \( X = B\text{PGL}_n \). Then the cohomological Brauer group \( \text{Br}'(X) \) is cyclic of order \( n \), the obstruction class of the universal bundle \( P \to X \) is a generator, and \( \text{Br}(X) = \text{Br}'(X) \).

*Proof.* Clearly, the Lie group \( \text{PGL}_n \) is connected. As \( \text{PSL}_n \to \text{PGL}_n \) is the universal covering with fiber \( \mu_n \), the \( n \)th roots of unity, its fundamental group is cyclic of order \( n \). Thus the classifying space \( X = B\text{PGL}_n \) is simply connected, and Hurewicz shows that \( H_2(X) = \pi_2(X) = \pi_1(\text{PGL}_n) \cong \mathbb{Z}/n\mathbb{Z} \). Thus the same holds for \( \text{Br}'(X) \) by Proposition 1.1. According to Proposition 2.1 there is a numerable \( \text{PGL}_n \)-bundle over some space whose obstruction class has order \( n \). Thus the same holds for the universal bundle \( P \to X \). If follows that \( \text{Br}(X) \subset \text{Br}'(X) \) is an equality. \( \Box \)

According to a result of Woodward [49], see also [2], equality \( \text{Br}(X) = \text{Br}'(X) \) holds for all CW-complexes of dimension \( \leq 4 \); in fact, each cohomology class \( \alpha \in \text{Br}'(X) \) is the obstruction of some \( \text{PGL}_n \)-bundle \( V \to X \) with \( n = \text{ord}(\alpha) \).

This applies, for example, to differential manifolds of dimension at most four, or the underlying topological space \( X = S(\mathbb{C}) \) of an algebraic \( \mathbb{C} \)-scheme or complex spaces \( S \) of complex dimension at most two. Note that all such spaces admit a CW-structure. It also applies to the underlying topological space \( X = S(\mathbb{C}) \) of complex Stein spaces \( S \) of complex dimension at most four, because such spaces have the homotopy type of a CW-complex of real dimension at most four by [23].

In higher dimensions, the following criterion reduces the problem to odd-dimensional CW-complexes:
Lemma 2.3. Let $X$ be a CW-complex of even dimension $n$, with $(n-1)$-skeleton $Y=X^{n-1}$. Let $\alpha \in \text{Br}'(X)$ be a class whose restriction $\alpha|Y$ lies in the Brauer group $\text{Br}(Y) \subset \text{Br}'(Y)$. Then $\alpha \in \text{Br}(X)$.

Proof. The cases $n=0,2$ are trivial, for then $H_2(X)$ is free, so $\text{Br}'(X)$ vanishes by Corollary 1.2. Now suppose $n \geq 4$. Choose some $\text{PGL}_d$-bundle $V \to Y$ whose obstruction class is $\alpha|Y$. Let $\varphi : \Pi S^n_{\alpha} \to Y$ be the attaching maps for the $n$-cells. The pullbacks $\varphi^*_a(V)$ correspond to elements in

$$\pi_{n-2}(\text{PGL}_d) = \pi_{n-2}(\text{GL}_d) = \pi_{n-2}(U(d)).$$

Replacing $V$ by the tensor product with a suitable trivial bundle, we may assume that $2d+1 > n-1$. The fibration $U(d+1)/U(d) = S^{2d+1}$ shows that we are in the stable range. We than have $\pi_{n-2}(U(d)) = \pi_{n-2}(U) = 0$, because $n$ is even, compare [39], Section 3.1. Thus the pullbacks $\varphi^*_a(V)$ are trivial, so the classifying map $Y \to \text{BGL}_d$ for $V$ can be extended to $X$. The resulting bundle on $X$ has $\alpha$ as obstruction class, since the restriction map $\text{Br}'(X) \to \text{Br}'(Y)$ is bijective. □

Proposition 2.4. Let $X$ be a finite-dimensional CW-complex that contains no cells of odd dimension $n \geq 5$. Then $\text{Br}(X) = \text{Br}'(X)$.

Proof. Let $X^n \subset X$ be the $n$-skeleton. We check $\text{Br}(X^n) = \text{Br}'(X^n)$ by induction on $n \geq 4$. Equality holds for $n=4$ by [19]. Now suppose $n \geq 5$, and that equality holds for $n-1$. If $n$ is even, we may apply Lemma 2.3. If $n$ is odd, then $X^n = X^{n-1}$, and equality holds as well. □

3. Eilenberg–MacLane spaces

We now examine the Brauer group of Eilenberg–MacLane spaces $X$ of type $K(G,j)$, which we always regard as connected CW-complexes endowed with a universal cohomology class. For $j \geq 3$, such spaces have trivial cohomological Brauer group, according to Corollary 1.2. In particular, this holds for $K(\mathbb{Z},3)$, although for paracompact $Y$ every torsion cohomology class in $H^3(Y,\mathbb{Z})$, which correspond to an element of the cohomological Brauer group, arises as a pullback of the universal cohomology class on $K(\mathbb{Z},3)$.

The cases of interest are $j=1$ and $j=2$. By Proposition 1.1 an Eilenberg–MacLane space $X$ of type $K(\mathbb{Q}/\mathbb{Z},2)$ has trivial cohomological Brauer group, although any torsion class in degree three on $Y$ arises as the Bockstein of the pullback of the universal cohomology class. Similarly for the classifying space

$$\text{BPGL}_\infty = K(\mathbb{Q}/\mathbb{Z},2) \times K(\mathbb{Q},4) \times K(\mathbb{Q},6) \times \ldots.$$

According to Proposition 1.1 the cohomological Brauer group of $K(\mathbb{Z}/n\mathbb{Z},2)$ is cyclic of order $n$. Antieau and Williams proved the following result, using multiplicative properties of the cohomology ring $H^*(PU(n),\mathbb{Z})$ with respect to the torsion subgroup ([1], Corollary 5.10):

Theorem 3.1. The Brauer group of $K(\mathbb{Z}/n\mathbb{Z},2)$ is trivial.

The special case $n=2$ was already considered by Atiyah and Segal, compare [1], proof of Proposition 2.1 (v). Another proof relying on the homotopy theory of classifying spaces that might be of independent interest appears at the end of this section.
What can be said about Eilenberg–MacLane spaces \( X \) of type \( K(G, 2) \), where the abelian group \( G \) is arbitrary? Then \( H_2(X) = \pi_2(X) = G \), and Proposition 1.1 gives an inclusion \( \text{Br}'(X) \subset \text{Ext}^1(G, \mathbb{Z}) \).

**Proposition 3.2.** Assumptions as above. With respect to the inclusion \( \text{Br}'(X) \subset \text{Ext}^1(G, \mathbb{Z}) \), the Brauer group is contained in the subgroup

\[ \text{Ext}^1(G/\text{Torsion}, \mathbb{Z}) \subset \text{Ext}^1(G, \mathbb{Z}). \]

**Proof.** Let \( T \subset G \) be the torsion subgroup. The short exact sequence of abelian groups

\[ 0 \to T \to G \to G/T \to 0 \]

yields an exact sequence

\[ \text{Hom}(T, \mathbb{Z}) \to \text{Ext}^1(G/T, \mathbb{Z}) \to \text{Ext}^1(G, \mathbb{Z}) \to \text{Ext}^1(T, \mathbb{Z}) \to 0 \]

(recall that for abelian groups there are no higher Ext groups). The term on the left vanishes, hence the map on the right indeed is injective. Consider the collection \( G_\alpha \subset G \) of all finite cyclic subgroups. This gives another short exact sequence

\[ 0 \to H \to \bigoplus \alpha G_\alpha \to T \to 0 \]

for some torsion group \( H \). In turn, we get a commutative diagram with exact rows and columns

\[
\begin{array}{cccccc}
0 & \to & \text{Ext}^1(G/T, \mathbb{Z}) & \to & \text{Ext}^1(G, \mathbb{Z}) & \to & \text{Ext}^1(T, \mathbb{Z}) & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & \prod \alpha \text{Ext}^1(G_\alpha, \mathbb{Z}) & \to & \prod \alpha \text{Ext}^1(G_\alpha, \mathbb{Z}) & \to & \prod \alpha \text{Ext}^1(G_\alpha, \mathbb{Z}) & \to & 0
\end{array}
\]

Seeking a contradiction, we assume that there is a bundle \( V \to X \) whose obstruction class viewed as an element \( \alpha \in \text{Ext}^1(G, \mathbb{Z}) \) does not lie in the subgroup \( \text{Ext}^1(G/T, \mathbb{Z}) \). By the preceding diagram, there must be an inclusion \( \mathbb{Z}/n\mathbb{Z} \subset G \) so that the \( \alpha \) restricts to a nonzero element in \( \text{Ext}^1(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}) \). Consider the induced map

\[ f : K(\mathbb{Z}/n\mathbb{Z}, 2) \to K(G, 2) = X \]

of Eilenberg–MacLane spaces. Then \( f^*(V) \) is a bundle with nontrivial obstruction class, in contradiction to Theorem 3.1. \( \square \)

We conjecture that the Brauer groups for arbitrary Eilenberg–MacLane spaces of type \( K(G, 2) \) vanish. In any case, its elements are “phantoms”:

**Theorem 3.3.** Let \( X \) be a CW-complex and \( n \geq 0 \). Then the subgroup

\[ \text{Ext}^1(H_{n-1}(X)/\text{Torsion}, \mathbb{Z}) \subset H^n(X) \]

comprises precisely those classes which vanish on all finite subcomplexes.

**Proof.** According to a generalization ([3], Corollary 12) of Milnor’s exact sequence ([35], Lemma 2), we have a natural short exact sequence

\[ 0 \to \lim \lim H^{n-1}(X_\alpha) \to H^n(X) \to \lim \lim H^n(X_\alpha) \to 0, \]

where \( X_\alpha \subset X \) is the ordered set of finite subcomplexes. The Universal Coefficient Theorem gives short exact sequences

\[ 0 \to \text{Ext}^1(H_{n-2}(X_\alpha), \mathbb{Z}) \to H^{n-1}(X_\alpha) \to \text{Hom}(H_{n-1}(X_\alpha), \mathbb{Z}) \to 0. \]
The groups $H_{n-2}(X_α)$ are finitely generated, since $X_α$ are finite CW-complexes. Hence $\text{Ext}^1(H_{n-2}(X_α), \mathbb{Z})$ are non-canonically isomorphic to the torsion part of $H_{n-2}(X_α)$, whence finite. According to [29], Corollary 7.2, the higher derived inverse limits of such groups vanish. Thus the map

$$\lim^1 H^{n-1}(X_α) \rightarrow \lim^1 \text{Hom}(H_{n-1}(X_α), \mathbb{Z})$$

in the long exact sequence for inverse limits is bijective. Clearly, we have

$$\text{Hom}(H_{n-1}(X_α), \mathbb{Z}) = \text{Hom}(H_{n-1}(X_α)/\text{Torsion}, \mathbb{Z}).$$

Moreover, the canonical map $\lim H_{n-1}(X_α) \rightarrow H_{n-1}(X)$ is bijective. One easily sees that the induced map

$$\lim(H_{n-1}(X_α)/\text{Torsion}) \rightarrow H_{n-1}(X)/\text{Torsion}$$

is bijective as well. By Jensen’s observation ([29], page 37), we have an identification

$$\lim^1 \text{Hom}(H_{n-1}(X_α)/\text{Torsion}, \mathbb{Z}) = \text{Pext}^1(H_{n-1}(X)/\text{Torsion}, \mathbb{Z}),$$

where the right hand side is the group of isomorphism classes of pure extensions. Recall that an extension in the category of abelian groups $0 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 0$ is called pure if it remains exact after tensoring with arbitrary groups. The isomorphism classes of pure extensions form a subgroup

$$\text{Pext}^1(G'', G') \subset \text{Ext}^1(G'', G').$$

According to [13], §53.3, this subgroup is the first Ulm subgroup. Recall that for an abelian group $E$, the first Ulm subgroup is $U^1(E) = \bigcap_{m \geq 1}(mE)$. However, for any torsion free abelian group $F$, the group $\text{Ext}^1(F, \mathbb{Z})$ is divisible (compare [15], page 223, point (I)), hence the latter coincides with its own first Ulm subgroup. Combining these observations, one infers the assertion.

**Remark 3.4.** The equality $\lim^1 H^{n-1}(X_α) = \text{Pext}^1(H_{n-1}(X)/\mathbb{Z})$ was already shown by M. Huber and Meier [25]. For a general treatment of “phantoms”, we refer to McGibbon [33] and Rudyak [39], Chapter III.

**Another proof for Theorem 3.7.** Let $X$ be an Eilenberg–MacLane space of type $K(\mathbb{Z}/n\mathbb{Z}, 2)$. Consider the Bockstein exact sequence

$$H^2(X, \mathbb{Z}) \rightarrow H^2(X, \mathbb{Z}/n\mathbb{Z}) \rightarrow H^3(X, \mathbb{Z}) \rightarrow H^3(X, \mathbb{Z}) \rightarrow n.$$ 

The term on the left vanishes, by Hurewicz and the Universal Coefficient Theorem. In turn, the Bockstein map $H^2(X, \mathbb{Z}/n\mathbb{Z}) \rightarrow H^3(X, \mathbb{Z})$ is injective, and its image equals $\text{Br}'(X) \subset H^3(X, \mathbb{Z})$, which is cyclic of order $n$. Denote by $\bar{\alpha} \in H^2(X, \mathbb{Z}/n\mathbb{Z})$ the universal cohomology class, which generates this cyclic group, and $\alpha \in \text{Br}'(X)$ the corresponding cohomological Brauer class. Seeking a contradiction, we suppose that there is a non-zero multiple $\beta = \gamma \cdot \alpha$ lying in $\text{Br}(X)$. Choose a $\text{PGL}_m$-bundle $V \rightarrow X$ whose obstruction class is $\beta$. As $m \cdot \beta = 0$, the number $m$ is a multiple of $\text{ord}(\beta) = n/gcd(n, r)$. Tensoring $V$ with the trivial $\text{PGL}_{gcd(n, r)}$-bundle, we may assume that $n|m$.

The existence of this bundle $V$ has the following consequence: Let $Y$ be an arbitrary paracompact space and $\gamma \in \text{Br}'(Y)$ an element of order $n$. Viewing it as a torsion class in $H^3(Y, \mathbb{Z})$, we may choose some $\tilde{\gamma} \in H^2(Y, \mathbb{Z}/n\mathbb{Z})$ mapping to $\gamma$ under the Bockstein. This $\tilde{\gamma}$ corresponds to a homotopy class of continuous maps $h : Y \rightarrow X$, and the $\text{PGL}_m$-bundle $h^*(V)$ on $Y$ has obstruction $r \cdot \gamma$. We will reach
a contradiction below by exhibiting a paracompact space $Y$ and a class $\gamma \in \text{Br}^r(Y)$ of order $n$ so that $r \cdot \gamma$ does not come from a $\text{PGL}_m$-bundle.

We construct such a space $Y$ as a relative CW-complex by attaching a single cell to the classifying space $B = BP\text{GL}_m$. Using that $\pi_i(B)$ are finite groups for $i \leq 3$, we infer with Serre’s refined Hurewicz Theorem [44] that the canonical map $\pi_4(B) \to H_4(B)$ becomes bijective after tensoring with $\mathbb{Q}$. Since $\pi_4(B) \simeq \mathbb{Z}$, there is a continuous map $\varphi : S^4 \to B$ so that the induced map $H_4(S^4, \mathbb{Q}) \to H_4(B, \mathbb{Q})$ is bijective. The cocartesian diagram

\[
\begin{array}{ccc}
S^4 & \longrightarrow & D^5 \\
\downarrow_{\varphi} & & \downarrow_{\Phi} \\
B & \longrightarrow & Y
\end{array}
\]

defines a relative CW-complex $B \subset Y$. Then we have a long exact sequence

\[
H^i(Y, B) \longrightarrow H^i(Y) \longrightarrow H^i(B) \longrightarrow H^{i+1}(Y, B)
\]

of relative singular cohomology groups with integral coefficients. The relative cohomology groups $H^i(Y, B)$ can be computed using the cellular cochain complex, thus vanish for $i \neq 5$ (see for example [48], Chapter II, Theorem 2.19). In particular, the restriction map $H_4(B, \mathbb{Z}) \to H_4(B, \mathbb{Q})$ is bijective.

The obstruction class $\gamma_u \in \text{Br}(B)$ of the universal bundle on $B$ has order $m$, by Proposition 2.2. Let $\gamma \in \text{Br}^r(Y)$ be the unique class restricting to $m/n \cdot \gamma_u$, which has order $n$. As explained above, this yields a certain $\text{PGL}_m$-bundle $h^*V$ on $Y$ with obstruction class $r \cdot \gamma$, which in turn is classified by a continuous map $f : Y \to B = BP\text{GL}_m$. Consider the commutative diagram

\[
\begin{array}{ccc}
S^4 & \longrightarrow & D^5 \\
\downarrow_{\varphi} & & \downarrow_{\Phi} \\
B & \longrightarrow & Y & \longrightarrow & B.
\end{array}
\]

The map $g \circ \varphi$ factors over $D^5$, whence is homotopic to a constant map. We infer that the map $g_* : H_4(B, \mathbb{Q}) \to H_4(B, \mathbb{Q})$ is zero.

On the other hand, $g : B \to B$ is not homotopic to a constant map, because $r \cdot \gamma|B = rm/n \cdot \gamma_u \neq 0$. Theorem 3.5 below implies that $g_* : H_4(B, \mathbb{Q}) \to H_4(B, \mathbb{Q})$ is bijective, contradiction.

We have just used the following result of Jackowski, McClure and Oliver [28]:

**Theorem 3.5.** Let $G$ be a compact, connected simple Lie group. Then for every nontrivial element $g \in [BG, BG]$, there is a positive integer $k$ and an $\alpha \in \text{Out}(G)$ such that $g = B\alpha \circ \psi^k$ where $\psi^k$ is a so-called unstable Adams operation, having the property that $H^{2i}(\psi^k, \mathbb{Q})$ is multiplication by $k^i$.

Actually, the units in the monoid of homotopy classes $[BG, BG]$ is the group of outer automorphisms $\text{Out}(G)$, and the corresponding quotient has an embedding

\[
[BG, BG]/[BG, BG]^\times \subset \mathbb{N}
\]

into the multiplicative monoid of the integers. Its image consists of $k = 0$ and all $k > 0$ prime to the order of the Weyl group of $G$. These numbers $k > 0$ correspond
to the unstable Adams operations $\psi^k$, which are defined in terms of the Galois action of Gal($\mathbb{Q}$) on Grassmannians. First examples of unstable Adams operations were constructed by Sullivan \cite{Sullivan}. This result apply in particular for the compact Lie group $G = \text{PU}(n)$. Since $\text{BPU}(n) \to \text{BPGL}_n$ is a homotopy equivalence and $\text{PU}(n)$ is a compact, connected simple Lie group, it applies to our situation.

4. PLUS CONSTRUCTION AND CLASSIFYING SPACES

In this final section we study Eilenberg–MacLane spaces of type $K(G, 1)$, that is, classifying spaces for discrete groups. Somewhat surprisingly, this turns out to be, in some sense, the universal situation.

Let $X$ be a CW-complex, and $N \subset \pi_1(X)$ be normal subgroup that is perfect, i.e., $N$ coincides with its commutator subgroup $[N, N]$. The plus construction $X \subset X^+$ is a relative CW-complex obtained by attaching certain cells of dimension two and three, such that the following holds:

(i) $\pi_1(X) \to \pi_1(X^+)$ is surjective, with kernel $N$.
(ii) $H_*(X) \to H_*(X^+)$ is bijective.

It has the following universal property: For every CW-complex $Y$ and every continuous map $f : X \to Y$ such that $N$ is contained in the kernel of $\pi_1(X) \to \pi_1(Y)$, there is a unique homotopy class of continuous maps $f^+ : X^+ \to Y$ so that $f^+|_X$ is homotopic to $f$. The plus construction was first introduced by Kervaire \cite{Kervaire}, and used by Quillen to define the higher $K$-groups for rings \cite{Quillen}.

Proposition 4.1. Let $X$ be a CW-complex. Then the restriction maps $\text{Br}'(X^+) \to \text{Br}'(X)$ and $\text{Br}(X^+) \to \text{Br}(X)$ are bijective.

Proof. Since $H_2(X) \to H_2(X^+)$ is bijective, the induced map on cohomological Brauer groups is bijective, according to Proposition \ref{prop:cohomological-conjugacy}. In turn, the map on Brauer groups is injective, and it remains to check that every bundle on $X$ extends to $X^+$. Since the classifying space $\text{BPGL}_n$ is simply connected, every continuous mapping $f : X \to \text{BPGL}_n$ extends to $X^+$ by the universal property of the plus construction.

We thus have canonical identifications

$$\text{Br}'(X^+) = \text{Br}'(X) \quad \text{and} \quad \text{Br}(X^+) = \text{Br}(X).$$

Now let $Y$ be a connected CW-complex. According to a result of Kan and Thurston \cite{KanThurston}, there is a group $G$, a perfect normal subgroup $N \subset G$, and a homotopy equivalence

$$(BG)^+ \to Y.$$

Here $BG$ denotes the classifying space of the discrete group $G$, defined in a functorial way as a geometric realization of the nerve of category with a single object and morphism set $G$, and $(BG)^+$ is the plus construction with respect to $N \subset G = \pi_1(BG)$. Note that this group $G$ is often uncountable, but in any case we have

$$\text{Br}'(Y) = \text{Br}(BG) \quad \text{and} \quad \text{Br}(Y) = \text{Br}(BG)$$

by Proposition \ref{prop:br-equivalence}. Concerning the question of equality of $\text{Br}(X) \subset \text{Br}'(X)$, we are thus reduced to the case $X = BG$ for discrete groups $G$. This translates part of the question from algebraic topology into group theory, as we have

$$\text{Br}'(BG) = \text{Torsion Ext}^1(H_2(G)/\text{Divisible}, \mathbb{Z})$$
by Proposition 4.1. Recall that \( H_2(G) = H_2(G, \mathbb{Z}) \) is often referred to as the Schur multiplier. For \( G \) finite, the Schur multiplier is finite, and thus non-canonically isomorphic to \( \text{Br}'(BG) \).

Let us now recall a fundamental notion from abelian group theory: Suppose \( G \) is an abelian torsion group. A subgroup \( H \subseteq G \) is called basic if the following three conditions hold:

(i) The group \( H \) is isomorphic to a direct sum of cyclic groups.

(ii) The residue class group \( G/H \) is divisible.

(iii) For each integer \( n \), the inclusion \( nH \subseteq nG \cap H \) is an equality.

Basic subgroups \( H \subseteq G \) always exist, and the isomorphism class of the abstract group \( H \) is unique. The theory of basic subgroups goes back to Kulikof [32], who treated the case that \( G \) is \( p \)-primary, that is, the orders of group elements are \( p \)-power. For the general situation, compare [15], Chapter VI, Section 33.

**Theorem 4.2.** Let \( p > 0 \) be a prime, and \( G \) be a \( p \)-primary torsion group whose basic subgroups \( H \subseteq G \) are infinite. Then the classifying space \( X = BG \) has the property \( \text{Br}(X) \cong \text{Br}'(X) \).

This applies in particular to the case that \( G \) is an infinite-dimensional \( \mathbb{F}_p \)-vector space. The proof relies on a series of facts, which we have to establish first. To begin with, recall that for every abelian group, the addition map \( G \times G \to G \) induces on the graded homology module \( H_\ast(G) \) the structure of an alternating associative ring. Therefore, the canonical bijection \( G \to H_1(G) \) yields a ring homomorphism \( \Lambda^\ast(G) \to H_\ast(G) \) from the exterior algebra to the homology ring.

**Proposition 4.3.** For every abelian group \( G \), the canonical map \( \Lambda^2(G) \to H_2(G) \) is bijective. If \( G \) is torsion and \( H \subseteq G \) is a basic subgroup, the induced map \( H_2(H) \to H_2(G) \) is bijective as well.

**Proof.** The first assertion appears in [19], Chapter V, Theorem 6.4. Now let \( G \) be torsion, and \( H \subseteq G \) a basic subgroup. The task is to check that the canonical map

\[
\Lambda^2(H) \to \Lambda^2(G)
\]

is bijective. We start with surjectivity. Let \( g \wedge g' \in \Lambda^2(G) \). Choose \( n > 0 \) with \( ng' = 0 \). Using that \( G/H \) is divisible, we may write \( g = na + h \) with \( a \in G \) and \( h \in H \). Then \( g \wedge g' = h \wedge g' = -g' \wedge h \). Repeating the argument, we see that \( g \wedge g' = h \wedge h' \) for some \( h, h' \in H \).

It remains to check injectivity. Suppose we have a nonzero element \( x \in \Lambda^2(H) \). Since \( H \) is a direct sum of finite cyclic groups, so is \( \Lambda^2(H) \). This implies that there is an integer \( n \neq 0 \) with \( x \notin n\Lambda^2(H) \). Since \( nH = H \cap nG \), the canonical map of \( \mathbb{Z}/n\mathbb{Z} \)-modules \( H/nH \to G/nG \) is injective (in fact bijective). It follows that the image of \( x \) in

\[
\Lambda^2(H) \otimes \mathbb{Z}/n\mathbb{Z} = \Lambda^2(H/nH) = \Lambda^2(G/nG)
\]

is nonzero, thus the same holds in \( \Lambda^2(G) \).

**Corollary 4.4.** Let \( G \) be an abelian torsion group, with basic subgroup \( H \) of the form \( H = \bigoplus_{i \in I} \mathbb{Z}/n_i\mathbb{Z} \). Then the cohomological Brauer group \( \text{Br}'(X) \) of the classifying space \( X = BG \) is isomorphic to the torsion part of \( \prod_{i \leq j} \mathbb{Z}/(n_i, n_j) \).
Proof: We have \( H_2(G) = \Lambda^2(H) \) by the Proposition. Using \( \Lambda^2(\mathbb{Z}/n_i\mathbb{Z}) = 0 \), one obtains a decomposition
\[
\Lambda^2(H) = \bigoplus_{i < j} \Lambda^1(\mathbb{Z}/n_i\mathbb{Z}) \otimes \Lambda^1(\mathbb{Z}/n_j\mathbb{Z}) = \bigoplus_{i < j} \mathbb{Z}/(n_i, n_j).
\]

Here we have chosen a total order on the index set \( I \). Proposition 1.1 together with the fact that \( \text{Ext}^1(\mathbb{Z}/d\mathbb{Z}, \mathbb{Z}) \), \( d \neq 0 \) is non-canonically isomorphic to \( \mathbb{Z}/d\mathbb{Z} \), now yields the result.

Next, we need a result that allows us to pass back, in rather special circumstances, from bundles over classifying spaces to representations. Given a representation \( \rho : \pi_1(X) \to L \) in some Lie group \( L \), we obtain an associated \( L \)-bundle \( V \to X \), which is defined as the quotient of \( L \times X \) modulo the diagonal action of the fundamental group. Such bundles are called flat. We are mainly interested in the case \( X = BG \), where \( \pi_1(X) = G \), and \( L = PU(n) \subset \text{PGL}_n \).

**Proposition 4.5.** Let \( p > 0 \) be a prime, and \( G \) be a group that is an ascending union of subgroups \( G_0 \subset G_1 \subset \ldots \). Suppose that the \( G_j \) are finite \( p \)-groups and that the inclusion homomorphisms \( G_j \subset G_{j+1} \) admit left inverses. Then every \( \text{PGL}_n \)-bundle on the classifying space \( X = BG \) is associated to a representation \( G \to PU(n) \).

Proof. We have \( BG = \bigcup_j BG_j \). Let \( V \to BG \) be a \( \text{PGL}_n \)-bundle of rank \( n \geq 0 \), and write \( V_j = V|BG_j \) for the restrictions. By a result of Dwyer and Zabrodsky [11], the canonical maps
\[
\text{Hom}(G_i, PU(n)) \to [BG_i, BPU(n)] = [BG_i, \text{BPGL}_n]
\]
are surjective. Choose a representation \( \rho_j : G_j \to PU(n) \) so that \( V_j \) is isomorphic to the bundle associated to \( \rho_j \). For each \( j \), the representations \( \rho_{j+1}|G_j \) and \( \rho_j \) are conjugate. This follows from [HS], Chapter V, Corollary 4.4. Replacing inductively the \( \rho_{j+1} \) by suitable \( a_j^{-1} \rho_{j+1} a_j \), we may assume that \( \rho_{j+1}|G_j = \rho_j \). In turn, we get a representation \( \rho : G \to PU(n) \) with \( \rho|G_j = \rho_j \). Consider the associated \( \text{PGL}_n \)-bundle \( W \to BG \). By construction, the bundles \( V, W \) restrict to isomorphic bundles on each \( BG_j \).

It remains to verify that two \( \text{PGL}_n \)-bundles \( V, W \) of rank \( n \) that are isomorphic on each \( BG_j \) are isomorphic. Let \( V_j, W_j \) be the restrictions to \( BG_j \). Since \( V = \bigcup V_j \) and \( W = \bigcup W_j \), it suffices to construct compatible bundle isomorphism \( f_j : V_j \to W_j \). We do this by induction on \( j \geq 0 \). Choose an arbitrary isomorphism \( f_0 \), and suppose we already have a compatible family \( f_0, \ldots, f_j \). Let \( P_{j+1} \to BG_{j+1} \) be the \( \text{PGL}_n \)-torsor of bundle isomorphism \( V_{j+1} \to W_{j+1} \). Then \( P_{j+1}|BG_j \) is isomorphic to \( P_j \to BG_j \). By assumption, all these torsors admit a section, thus are isomorphic to the trivial torsor. To conclude the proof, it therefore suffices to verify that every continuous function \( BG_j \to \text{PGL}_n \) extends along the inclusion \( BG_j \subset BG_{j+1} \). But this is trivial, because our left inverses \( l_{j+1} : G_{j+1} \to G_j \) for the inclusions \( G_j \subset G_{j+1} \) induce by functoriality continuous maps \( Bl_{j+1} : BG_{j+1} \to BG_j \) that are the identity on \( BG_j \).

**Proposition 4.6.** Let \( G \) be an abelian group, and \( V \to BG \) the \( \text{PGL}_n \)-bundle associated to a representation \( \rho : G \to PU(n) \). Then there is a subgroup \( M \subset G \) of finite index so that the restriction \( V|BM \) comes from a vector bundle of rank \( n \).
Proof. This is essentially a result on unitary representations of discrete groups due to Backhouse and Bradley [5]. For the sake of the reader, we briefly recall parts of their argument in our setting. For each \( g \in G \), choose a matrix \( A_g \in SU(n) \) representing \( \rho(g) \in PU(n) \). Make the choice so the \( A_e \) is the unit matrix for the neutral element \( e \in G \). Now define the multiplier \( \omega_{g,h} \in \mu_n \) by the formula

\[
A_g \cdot A_h = \omega_{g,h} \cdot A_{gh}.
\]

Then the 2-cochain \( \omega_{g,h} \) is a cocycle, and its cohomology class in \( H^2(G, C^\times) \) is precisely the obstruction against lifting the projective representation \( \rho \) to a linear representation.

On the other hand, one may use this 2-cocycle to endow the set \( \hat{G} = \mu_\infty \times G \) with the structure of a central extension of \( G \), by declaring the group law as

\[
(\zeta, g) \cdot (\xi, h) = (\zeta \omega_{g,h}, gh).
\]

Here \( \mu_\infty \subset C^\times \) is the group of all complex roots of unity. The representation \( \rho : G \to PU(n) \) yields a unitary representation \( \hat{\rho} : \hat{G} \to U(n) \), defined via \( \hat{\rho}(\zeta, g) = \zeta A_g \). We may assume that the latter linear representation is irreducible, by passing to an irreducible subrepresentation. This replaces \( n \) by some \( n' \leq n \), but does not affect the multiplier.

Using Zorn’s Lemma, one checks that there is a maximal subgroup \( M \subset G \) on which the multiplier is symmetric, that is, \( \omega_{g,h} = \omega_{h,g} \) for all \( g, h \in M \). Consider the induced central extension \( \hat{M} = \hat{G} \times_G M \) of \( M \). Obviously, the group \( \hat{M} \) is abelian, and we may view \( 0 \to \mu_\infty \to \hat{M} \to M \to 0 \) as an extension in the category of abelian groups. The latter extension splits, because \( \mu_\infty \) is divisible and hence \( Ext^1(M, \mu_\infty) \) vanishes. Consequently, the representation \( \rho : M \to PU(n) \subset PGL_n \) lifts to a linear representation \( M \to GL_n \).

It remains to verify that the subgroup \( M \subset G \) has finite index. This indeed holds by [5], Theorem 3. Note that in loc. cit. the irreducibility of the unitary representation of \( \hat{G} \) enters. There it is also shown that all irreducible unitary projective representation with multiplier \( \omega \) have the same dimension \( d(\omega) \), and that this dimension coincides with the index of \( M \subset G \).

Proof of Theorem 4.2. Let \( p > 0 \) be a prime and \( G \) be a \( p \)-primary torsion group whose basic subgroups \( H \subset G \) are infinite. Write \( H = \bigoplus_{i \in I} \mathbb{Z}/p^i \mathbb{Z} \). By the proof for Corollary 4.1, the cohomological Brauer group of \( BG \) is the torsion part of

\[
Ext^1(\Lambda^2(H), \mathbb{Z}) = \text{Hom}(\Lambda^2(H), \mathbb{Q}/\mathbb{Z}) = \prod_{i < j} \text{Hom}(\mathbb{Z}/(p^{\nu_i}, p^{\nu_j}), \mathbb{Q}/\mathbb{Z}).
\]

In particular, the canonical map \( BH \to BG \) induces a bijection on cohomological Brauer groups. Replacing \( G \) by \( H \), we may assume that \( G \) itself is a direct sum of cyclic groups. Restricting to a direct summand and permuting the summands, we may assume that the index set \( I \) is the set of natural numbers, and that \( \nu_i \leq \nu_j \) for \( i \leq j \).

Set \( X = BG \), and let \( \alpha \in Br'(X) \) be a torsion element. Write it as a tuple \( \alpha = (\alpha_{ij})_{i < j} \) with respect to the decomposition \( 9 \). For each \( i \in I \), let \( J_i \subset I \) be the set of \( j \in I \) with \( i < j \) and \( \alpha_{ij} \neq 0 \). Furthermore, let \( I_{\text{fin}} \subset I \) be the set of all \( i \in I \) with \( J_i \) finite. Now suppose that \( \alpha \) has the property that \( I \setminus I_{\text{fin}} \) is finite, and that the cardinalities of the sets \( J_i, i \in I_{\text{fin}} \) are unbounded. We claim that any such \( \alpha \) does not lie in the Brauer group.
Suppose to the contrary that there is a $\text{PGL}_n$-bundle $V \to X$ whose obstruction class is $\alpha$. Clearly, the assumptions of Proposition 4.5 hold for the subgroups $G_i = \bigoplus_{i=0}^t \mathbb{Z}/p^i\mathbb{Z}$ of $G$; hence our projective bundle is associated to a projective representation $\rho : G \to \text{PGL}_n$. By Proposition 4.6, there is a subgroup $M \subset G$ of finite index so that the projective representation lifts to a linear representation of the subgroup $M$. Thus $\alpha|\Lambda^2(M) = 0$.

To reach a contradiction, it remains to check that $\alpha$ remains nonzero on $\Lambda^2(M)$ for each subgroup $M \subset G$ of finite index. We do this by induction on the index $[G : M]$. The case $M = G$ is trivial, so let us assume $M \subsetneq G$. Choose a short exact sequence
\begin{equation}
0 \to G' \to G \to \mathbb{Z}/p\mathbb{Z} \to 0.
\end{equation}
with $M \subset G'$. We shall see that for some other subgroup $U \subset G'$, we may apply the induction hypothesis to $M \cap U \subset U$. Indeed, we have
\[ U/(M \cap U) = (U + M)/M \subsetneq G/M, \]
so $[U : M \cap U] < [G : M]$, and the problem is to choose $U$ admitting a suitable direct sum decomposition, so that $\alpha|\Lambda^2(U)$ retains its properties with respect to the new decomposition.

With respect to the given direct sum decomposition $G = \bigoplus_{i\geq 0} \mathbb{Z}/p^i\mathbb{Z}$, the map on the right in (4) can be viewed as a matrix $(\lambda_0, \lambda_1, \ldots)$ with $\lambda_k \in \mathbb{Z}/p\mathbb{Z}$. First, consider the case that $\lambda_k = 0$ for almost all $k \in I$, say for all $k \geq k_0$. Then obviously $U = \bigoplus_{i \geq k_0} \mathbb{Z}/p^i\mathbb{Z}$ does the job.

Suppose now that $\lambda_k \neq 0$ for infinitely many $k \in I$. Then there must be such an index with $J_k$ finite. Without restriction, we may assume $J_k = 1$. For $i \neq k$, choose lifts $X'_i \in \mathbb{Z}$ of $\lambda_i \in \mathbb{Z}/p\mathbb{Z}$, and consider $e'_i = e_i - X'_ie_k \in \mathbb{Z}$. Also set $e'_k = e_k$. Then the elements $e'_i \in \mathbb{Z}$, $i \geq 0$ form a new “basis”, and the $e'_i$, $i \neq k$ generate a subgroup $U \subset G$ contained in $G'$. In $\Lambda^2(G)$, we obviously have
\[ e'_i \wedge e'_j = e_i \wedge e_j - X'_ie_k \wedge e_j + X'_je_k \wedge e_i. \]
Decomposing $\alpha = (\alpha'_{ij})_{i<j}$ with respect to the new “basis” $e'_i \in \mathbb{Z}$ as in (3), the above formula shows that for all $i > k$, $i \notin J_k$, the condition $\alpha'_{ij} \neq 0$ is equivalent to $\alpha_{ij} \neq 0$, except for at most $\text{Card}(J_k)$ indices $j \in J_k$. It follows that the new tuple $(\alpha'_{ij})_{i<j}$ has the same properties as the original tuple $(\alpha_{ij})_{i<j}$, and the same holds if we restrict to indices $i, j \neq k$. The induction hypothesis applied to $M \cap U \subset U$ tells us that $\alpha$ remains nonzero on $\Lambda^2(M \cap U)$, thus in particular on $\Lambda^2(M)$.
