ABSTRACT—In cultured bovine adrenal chromaffin cells, pituitary adenylate cyclase-activating polypeptide (PACAP) stimulated [14C]catecholamine synthesis from [14C]tyrosine (but not from [14C]DOPA) in a concentration-dependent manner, causing maximal stimulation at 10^{-7} M. The stimulatory action of PACAP was not affected by staurosporine (an inhibitor of protein kinase C) or in the cells in which protein kinase C was down-regulated by prolonged exposure to TPA (an activator of protein kinase C), whereas it was partially attenuated in Ca^{2+}-free medium. PACAP (10^{-7} M) increased the formation of [3H]inositol phosphates, [Ca^{2+}], and 41 Ca^{2+} uptake as well as cAMP. The peptide also stimulated the phosphorylation of tyrosine hydroxylase, the enzyme catalyzing the rate-limiting step in catecholamine synthesis. Catecholamine synthesis and tyrosine hydroxylase phosphorylation stimulated by the maximal effective concentration of dibutyryl cAMP or high K^{+}, which activates Ca^{2+} uptake, were further enhanced by PACAP, suggesting that both cAMP- and Ca^{2+}-dependent protein kinases may be involved in the stimulation of tyrosine hydroxylase phosphorylation and catecholamine synthesis caused by PACAP.

Keywords: Pituitary adenylate cyclase-activating polypeptide, Catecholamine formation, Tyrosine hydroxylase, Phosphorylation, Chromaffin cell

Pituitary adenylate cyclase-activating polypeptide (PACAP) originally isolated from bovine hypothalamus stimulates adenylate cyclase activation in rat cultured pituitary cells (1, 2). In addition to brain, PACAP is widely distributed in other organs such as the testis, gastrointestinal tract and lung (3). The concentration of PACAP is also relatively high in the adrenal gland, in which the peptide stimulates the secretion of catecholamines mainly by the activation of voltage-dependent Ca^{2+} channels (4, 5).

Tyrosine hydroxylase, the rate-limiting enzyme in catecholamine synthesis, is phosphorylated and activated by cAMP/forskolin (an activator of adenylate cyclase), phorbol esters (activators of protein kinase C) or the elevation of the intracellular concentration of Ca^{2+} ([Ca^{2+}]) caused by nicotinic receptor stimulation, high K^{+}-induced depolarization or Ca^{2+} ionophores (6–8).

In bovine adrenal chromaffin cells, the phosphorylation and activation of tyrosine hydroxylase are mediated by cAMP-dependent and Ca^{2+}/calmodulin-dependent protein kinases/protein kinase C (6, 9, 10). We have reported the activation and phosphorylation of tyrosine hydroxylase by high K^{+}, cholinergic agonists, dibutyryl cAMP, phorbol esters and bioactive neuropeptides (bradykinin and vasoactive intestinal polypeptide) in adrenal chromaffin cells and pheochromocytoma PC-12 cells (11–14). However, little is known about the effect of PACAP on catecholamine biosynthesis. In the present study, we investigated the effects of PACAP on [14C]catecholamine synthesis and phosphorylation of tyrosine hydroxylase in cultured bovine adrenal chromaffin cells.

MATERIALS AND METHODS

Cell preparation and culture

Bovine adrenal chromaffin cells were dispersed enzymatically as described previously (15). The cells were plated in 35-mm culture dishes at a density of 2 × 10^6 cells/dish for standard experiments or on 22 × 22 mm cover glasses in 35-mm culture dishes at a density of 1 × 10^6 cells/dish for
measuring intracellular calcium. They were maintained for 3–5 days as monolayer cultures in Eagle's basal medium supplemented with 5% heat-inactivated fetal calf serum, 2 mM glutamine, penicillin (100 units/ml), streptomycin (100 μg/ml), gentamycin (40 μg/ml), fungizone (2.5 μg/ml) and 10 μM cytosine arabinoside.

Measurement of catecholamine synthesis

Catecholamine synthesis was measured as described previously (12). The cells were incubated at 37°C for 15 to 45 min in 1 ml of BSS (135 mM NaCl, 5.6 mM KCl, 1.2 mM MgSO4, 2.2 mM CaCl2, 10 mg glucose and 20 mM HEPES/NaOH; pH 7.4) containing 20 μM L-[14C]tyrosine (0.5 μCi). [14C]Catecholamine from L-[14C]tyrosine was isolated on aluminium hydroxide, and radioactivity was counted by liquid scintillation spectrometry (16). In some experiments, L-[14C]DOPA (50 μM, 0.5 μCi) was used as substrate instead of L-[14C]tyrosine. [14C]Catecholamine from L-[14C]DOPA was measured by ion-exchange chromatography on a Duolite C-25 column (16).

Measurement of inositol phosphates formation

Cells were incubated for 48 hr with 5 μCi/ml [3H]-inositol in inositol-free Dulbecco's modified Eagle's serum-free medium. Then the cells were preincubated in BSS containing 10 mM LiCl for 10 min at 37°C and incubated for 10 min with or without test compounds. The reaction was stopped by addition of ice-cold trichloroacetic acid solution (10%, final concentration). [3H]Inositol phosphates were measured by anion-exchange chromatography as described previously (17, 18).

Measurement of intracellular calcium with fura-2

The [Ca2+]i in single chromaffin cells was measured by the fluorescent Ca2+ indicator fura-2. The cells, which were cultured on cover glasses, were incubated at 37°C for 30 min in 1 ml of BSS containing 2 μM fura-2/acetoxymethyl ester. Then the cells on the cover glasses were transferred to a small incubation bath (approx. 0.5 ml) on the platform of a microscope. Fluorescence was measured in a single chromaffin cell on the cover glass using a fluorescence spectromicroscope (excitation, 340/380 nm; emission, 510 nm). The [Ca2+]i was calculated by the previously described equation (19).

Measurement of 45Ca2+ uptake

Incubation medium containing 6 μCi of 45Ca2+ was added to the cells. After incubation, the dishes were immediately chilled on ice and washed three times with ice-cold Ca2+-free BSS. The 45Ca2+ taken up into the cells was extracted with 1% Triton X-100 and counted in a liquid scintillation counter.

Measurement of cyclic AMP levels

3-Isobutyl-1-methylxanthine (0.5 mM) was added to all tissue culture dishes to prevent the breakdown of cAMP. The cells were scraped from the dishes into 10% trichloroacetic acid solution, and the samples were centrifuged to remove denatured proteins. The supernatant fractions were extracted by ethyl ether, and cAMP was isolated from the solutions on Dowex-50 columns by the method of Su et al. (20). The cAMP level was measured by enzyme immunoassay with an Amersham cAMP enzyme immunoassay system kit.

Measurement of phosphorylation of tyrosine hydroxylase

Phosphorylation of tyrosine hydroxylase in the cells was measured as described previously (14). The cells were incubated with [32P]phosphate (carrier-free; 1.5 mCi/ml) for 60 min at 37°C in BSS buffer, washed with prewarmed BSS (37°C) and incubated with or without test compounds for 30 min. The phosphorylated tyrosine hydroxylase was separated by antiserum specific for tyrosine hydroxylase. Then, the phosphorylated tyrosine hydroxylase was applied to SDS-polyacrylamide slab gel as described previously (21, 22). After electrophoresis, the [32P]phosphate incorporated into tyrosine hydroxylase was analyzed by measuring the density of the autoradiographic band on the gel corresponding to the purified [32P]tyrosine hydroxylase standard and by cutting out this band and determining its radioactivity by Cerenkov analysis.

Statistical analyses

The results are expressed as the mean ± standard error (S.E.). Statistical differences between two groups were determined by Student's t-test for unpaired observations and analyses of variance, respectively.

Chemicals

L-[14C]Tyrosine, 45CaCl2 and a cyclic AMP assay kit were obtained from Amersham Corp. (Tokyo). [32P]Phosphorus and myo-[2-3H]inositol were obtained from New England Nuclear Corp. (Tokyo). Pituitary adenylate cyclase-activating polypeptide1-38 and bradykinin were obtained from the Peptide Institute (Osaka). Dibutyryl cAMP and 12-O-tetradecanoyl phorbol 13-acetate (TPA) were from Sigma Chemical Co. (St. Louis, MO, USA), and forskolin and staurosporine were from Calbiochem-Behring (Tokyo). Other chemicals used were commercial products of reagent grade.

RESULTS

Effect of PACAP on catecholamine synthesis

Figure 1 shows the synthesis of [14C]catecholamine...
from [\textsuperscript{14}C] tyrosine caused by various concentrations of PACAP. PACAP, at concentrations between of $10^{-9}$ and $10^{-7}$ M, stimulated [\textsuperscript{14}C] catecholamine synthesis in a concentration-dependent manner; its maximal effect (190% increase) occurred at $10^{-7}$ M, and its half-maximal effective concentration ($EC_{50}$) was approximately $5\times10^{-9}$ M. PACAP, however, failed to stimulate [\textsuperscript{14}C] catecholamine synthesis from [\textsuperscript{14}C] DOPA (control, $3.7\pm0.4$ nmol/30 min/dish; PACAP-treated cells, $3.9\pm0.4$ nmol/30 min/dish), suggesting that PACAP increased the conversion of tyrosine to DOPA catalyzed by tyrosine hydroxylase, the rate-limiting step in catecholamine biosynthesis. As shown in Fig. 2, the stimulation of [\textsuperscript{14}C] catecholamine synthesis by PACAP ($10^{-7}$ M) proceeded linearly with the duration of incubation for at least 45 min.

**Effect of calcium ion on PACAP-stimulated catecholamine synthesis**

To know the stimulatory mode of PACAP in [\textsuperscript{14}C] catecholamine synthesis, we examined whether the effect of PACAP would be attenuated in calcium-free medium. As shown in Fig. 3, the stimulatory effect of PACAP was diminished by 43% in calcium-free medium. We then examined the possible involvement of protein kinase C in

**Fig. 1.** Effects of various concentrations of PACAP on catecholamine synthesis in cultured bovine adrenal chromaffin cells. Cells were incubated at 37°C for 30 min in the presence or absence of various concentrations of PACAP. Catecholamine synthesis was determined as described in Materials and Methods. Data are means±S.E. for 4–6 separate experiments. a and b, Significantly more than the value without PACAP (P<0.01 and P<0.05, respectively).

**Fig. 2.** Time course of PACAP-stimulated catecholamine synthesis in cultured bovine adrenal chromaffin cells. Cells were incubated at 37°C for the indicated times in the presence (open circles) or absence (closed circles) of $10^{-7}$ M PACAP. Catecholamine synthesis was determined as described in Materials and Methods. Data are means±S.E. for 4–6 separate experiments. a, Significantly more than the value in the absence of PACAP (P<0.01).

**Fig. 3.** Effects of removal of extracellular Ca\textsuperscript{2+} on PACAP-, dibutyryl cAMP (DB-cAMP)- and high K\textsuperscript{+}-stimulated catecholamine synthesis in cultured bovine adrenal chromaffin cells. Cells were incubated at 37°C for 30 min in the presence or absence of $10^{-7}$ M PACAP, $7\times10^{-3}$ M DB-cAMP or $5.6\times10^{-2}$ M high K\textsuperscript{+} with (open columns) or without (hatched columns) extracellular Ca\textsuperscript{2+}. Catecholamine synthesis was determined as described in Materials and Methods. Data are means±S.E. for 4–6 separate experiments. Significance of differences at P<0.01: a, more than control value; b, less than PACAP-stimulated catecholamine synthesis; c, not significantly different from that on DB-cAMP stimulation; d, less than that on high K\textsuperscript{+} stimulation.
PACAP-stimulated \([^{14}C]\)catecholamine synthesis. The stimulatory effect of PACAP was not influenced by staurosporine (10\(^{-6}\) M), an inhibitor of protein kinase C, and by deprivation of protein kinase C from the cells by prolonged (24 hr) exposure to relatively high concentrations (10\(^{-6}\) M) of TPA (data not shown; see also refs. 23–26). It seems that the stimulation of catecholamine synthesis following PACAP treatment is dependent, in part, on extracellular calcium, but independent of protein kinase C. High K\(^{+}\) and dibutyryl cAMP also stimulated catecholamine synthesis, the effect of the former (but not the latter) being absolutely dependent on extracellular calcium.

Inositol 1,4,5-trisphosphate (IP\(_3\)) produced by the stimulation of phospholipase C is reported to mobilize Ca\(^{2+}\) from the intracellular storage pools (27). Figure 4 shows the effects of PACAP on the level of inositol phosphates and the effects of [Ca\(^{2+}\)]. PACAP (10\(^{-7}\) M) increased \([^{3}H]\)inositol phosphates by 141\% over the control. Bradykinin (10\(^{-6}\) M), which is known to increase IP\(_3\) in the adrenal chromaffin cells (28), elevated \([^{3}H]\)inositol phosphates by 356\%. In contrast, high K\(^{+}\) (5.6 \times 10\(^{-2}\) M) did not significantly increase \([^{3}H]\)inositol phosphates. PACAP (10\(^{-7}\) M) increased [Ca\(^{2+}\)], in a biphasic manner, and [Ca\(^{2+}\)], reached the levels of 238 and 618 nM at the initial rapid and a subsequent sustained phase, respectively. Bradykinin increased [Ca\(^{2+}\)], to 430 nM as a consequence of IP\(_3\)-stimulated release of Ca\(^{2+}\) from intracellular pools. High K\(^{+}\) increased [Ca\(^{2+}\)], to 890 nM through the activation of voltage-dependent calcium channels. Since PACAP induced a biphasic rise in [Ca\(^{2+}\)], we examined the effect of PACAP on \(^{45}\)Ca\(^{2+}\) uptake into adrenal chromaffin cells. As shown in Fig. 5, PACAP (10\(^{-7}\) M) and high K\(^{+}\) (5.6 \times 10\(^{-2}\) M) increased \(^{45}\)Ca\(^{2+}\) uptake by 102\% and 149\%, respectively, whereas bradykinin (10\(^{-6}\) M) had only a slight effect on \(^{45}\)Ca\(^{2+}\) uptake. These data, therefore, suggest that PACAP stimulates the release of Ca\(^{2+}\) from intracellular pools and the uptake of extracellular Ca\(^{2+}\) on adrenal chromaffin cells.

**Effect of PACAP on cAMP formation**

Figure 6 illustrates the effects of PACAP, forskolin.

**Fig. 4.** Effects of PACAP, high K\(^{+}\) and bradykinin on inositol phosphates level and [Ca\(^{2+}\)]. In cultured bovine adrenal chromaffin cells. A, Cells were maintained for 48 hr with 5 \(\mu\)Ci/ml \([^{3}H]\)inositol in inositol-free medium without serum. They were then preincubated at 37\(^{\circ}\)C for 10 min with 10 mM LiCl and incubated at 37\(^{\circ}\)C for 10 min with or without 10\(^{-7}\) M PACAP, 5.6 \times 10\(^{-2}\) M high K\(^{+}\) or 10 \(^{-4}\) M bradykinin with 10 mM LiCl. Accumulation of \([^{3}H]\)inositol phosphates was assayed as described in Materials and Methods. Data are means \(\pm\) S.E. for 3 separate experiments. a, Significantly more than the control value (\(P<0.01\)). B, Cells were incubated at 37\(^{\circ}\)C for 30 min with fura-2-acetoxy methyl ester. The 10\(^{-7}\) M PACAP (open circles), 5.6 \times 10\(^{-2}\) M high K\(^{+}\) (closed squares) or 10\(^{-4}\) M bradykinin (closed circles) was added at 0 time. Control values are shown by open squares. [Ca\(^{2+}\)] was determined as described in Materials and Methods. Data are means for 4 separate experiments. The maximal standard error was \(\pm\) 9.6\%. All peaks of fura-2 fluorescence with test compounds were significantly greater than the control level (\(P<0.01\)).
Fig. 5. Effects of PACAP, bradykinin and high K⁺ on 45Ca²⁺ uptake by cultured bovine adrenal chromaffin cells. Cells were incubated at 37°C for 30 min in the presence or absence of 10⁻⁷ M PACAP, 10⁻⁶ M bradykinin or 5.6 x 10⁻² M high K⁺. 45Ca²⁺ uptake into the cells was determined as described in Materials and Methods. Data are means±S.E. for 4–6 separate experiments. a and b, Significantly greater than the control value (P<0.01 and < 0.05, respectively).

Fig. 6. Effects of PACAP, high K⁺ and forskolin on cAMP formation in cultured bovine adrenal chromaffin cells. Cells were preincubated at 37°C for 10 min with 5 x 10⁻⁴ M 3-isobutyl-1-methylxanthine (IBMX) and then incubated at 37°C for 30 min with or without 10⁻⁷ M PACAP, 5.6 x 10⁻² M high K⁺ or 10⁻⁷ M or 10⁻⁶ M forskolin with IBMX. cAMP level in the cells was determined as described in Materials and Methods. Data are means±S.E. for 3 separate experiments. a, Significantly greater than the control value (P<0.01).

Fig. 7. Effects of PACAP, dibutyryl cAMP (DB-cAMP) and high K⁺ on catecholamine synthesis in cultured bovine adrenal chromaffin cells. Cells were incubated at 37°C for 30 min in the presence or absence of 10⁻⁷ M PACAP, 7 x 10⁻⁴ M DB-cAMP or 5.6 x 10⁻² M high K⁺. Catecholamine synthesis was determined as described in Materials and Methods. Data are means±S.E. for 4 separate experiments. All test compounds significantly increased catecholamine synthesis over the control value. a, Significantly greater than DB-cAMP-stimulated catecholamine synthesis (P<0.01); b, significantly greater than high K⁺-stimulated catecholamine synthesis (P<0.01).
(an activator of adenylate cyclase) and high K⁺ on cAMP level. PACAP increased cAMP to 709% of the control, which was comparable to that due to forskolin, while high K⁺ had no effect on cAMP. The concentrations of PACAP on cAMP formation were similar to those of ⁴⁵Ca²⁺ uptake and [¹⁴C]catecholamine synthesis in adrenal chromaffin cells (data not shown).

Effects of PACAP, dibutyryl cAMP and high K⁺ on catecholamine synthesis

Dibutyryl cAMP and high K⁺ are reported to increase catecholamine synthesis by the activation of tyrosine hydroxylase through cAMP-dependent protein kinase and calcium-dependent protein kinases, respectively (6, 29). As shown in Fig. 7, dibutyryl cAMP (7 x 10⁻³ M) or high K⁺ (5.6 x 10⁻² M), by itself, increased catecholamine synthesis by 120% or 150%, and their simultaneous application caused an additive increase (276%) in catecholamine synthesis. Although PACAP (10⁻⁷ M), by itself, increased catecholamine synthesis by 90% and also augmented the stimulatory effects of dibutyrly cAMP and high K⁺ from 120% and 152% to 196% and 228% respectively, the stimulatory effect of PACAP in combination of dibutyrly cAMP or high K⁺ was less than additive. Since the concentrations of PACAP, dibutyrly cAMP and high K⁺ used were those causing the maximal stimulation of catecholamine synthesis (11, 12, 14), our data suggest that PACAP-induced catecholamine synthesis may be mediated by both cAMP-dependent and calcium-dependent protein kinases.

Effect of PACAP, dibutyryl cAMP and high K⁺ on phosphorylation of tyrosine hydroxylase

As shown in Fig. 8, phosphorylation of tyrosine hydroxylase was stimulated 2.5-fold in the cells treated with PACAP (10⁻⁷ M). In addition, PACAP further enhanced the stimulatory effects of dibutyrly cAMP (7 x 10⁻³ M) and high K⁺ (5.6 x 10⁻² M) from 2.2- and 3.6-fold to 3.3- and 4.1-fold, respectively.

Fig. 8. Effects of PACAP, dibutyryl cAMP (DB-cAMP) and high K⁺ on phosphorylation of tyrosine hydroxylase in cultured bovine adrenal chromaffin cells. Cells were incubated at 37°C for 30 min in the presence or absence of 10⁻⁷ M PACAP, 7 x 10⁻³ M DB-cAMP or 5.6 x 10⁻² M high K⁺. Tyrosine hydroxylase phosphorylation was determined as described in Materials and Methods. Data are means ± S.E. for 3 separate experiments. All test compounds significantly increased tyrosine hydroxylase phosphorylation over the control value. a, Significantly greater than the value with DB-cAMP (P < 0.01); b, significantly greater than the value with high K⁺ (P < 0.01).
DISCUSSION

In cultured bovine adrenal chromaffin cells, we examined for the first time the mechanism(s) by which PACAP stimulates catecholamine synthesis. PACAP increased [14C]catecholamine synthesis from [14C]tyrosine (but not from [14C]DOPA) in a concentration-dependent manner, suggesting that PACAP increases the conversion of tyrosine to DOPA, a rate-limiting step in the biosynthesis of catecholamines.

We have previously found that the synthesis of catecholamines is increased in the cells treated with phorbol esters in a protein kinase C-related process(es) (12). Upon the breakdown of phosphatidylinositol 4,5-bisphosphate (PIP2) by phospholipase C (30), diacylglycerol, a physiological activator of protein kinase C that increases the affinity of the enzyme for Ca2+ (30, 31), is produced along with IP3 that mobilizes Ca2+ from the endoplasmic reticulum (27). Our previous (14) and present studies showed that bradykinin (10-6 M) increased the formation of inositol phosphates by 4.6-fold and elevated [Ca2+]i to 430 nM. PACAP, on the other hand, induced modest increases in inositol phosphates (2.4-fold) and [Ca2+]i (238 nM) (Fig. 4). Moreover, the stimulatory effect of PACAP on [14C]catecholamine synthesis was not inhibited by staurosporine or in the cells deprived of protein kinase C (data not shown). These results suggest that protein kinase C does not play a major role in the PACAP-induced catecholamine synthesis.

The activation of tyrosine hydroxylase by [Ca2+]i is thought to be mediated by calcium/calmodulin-dependent protein kinase in a number of in vitro and in situ systems (6, 32–34). In adrenal chromaffin cells, cAMP also stimulates the synthesis of catecholamines through cAMP-dependent protein kinase (6, 9, 11). In the present study, PACAP increased [Ca2+]i to 618 nM at a second sustained phase (Fig. 4) and increased Ca2+ uptake twofold (Fig. 5). The level of cAMP was also elevated eightfold by PACAP, which was comparable to the effect of forskolin (tenfold) (Fig. 6). We then examined whether PACAP stimulated catecholamine synthesis through either a cAMP- or Ca2+-dependent process. The increased synthesis of catecholamines caused by the maximal effective concentration of either dibutylryl cAMP or high K+ was further enhanced by PACAP, suggesting that the effect of PACAP may be mediated through a Ca2+/calmodulin- and cAMP-dependent process(es).

A previous study indicated (5) that PACAP-induced catecholamine secretion from cultured porcine adrenal chromaffin cells was inhibited by voltage-dependent Ca2+ channel blockers nicardipine and methoxyverapamil. Therefore, the increase in Ca2+ uptake into adrenal chromaffin cells caused by PACAP (Fig. 5) may be mediated by stimulation of voltage-dependent Ca2+ channels.

Since the phosphorylation of tyrosine hydroxylase results in its activation (6), we examined whether PACAP would stimulate the phosphorylation of tyrosine hydroxylase. Although PACAP itself increased the phosphorylation of tyrosine hydroxylase, the peptide also enhanced the phosphorylation of tyrosine hydroxylase caused by either dibutylryl cAMP or high K+. Phosphopeptide analysis of tyrosine hydroxylase in PC12 cells has demonstrated that 32P incorporation into three distinct phosphopeptides are stimulated by Ca2+/calmodulin-dependent, cAMP-dependent protein kinases and protein kinase C, respectively (14, 22, 29). Thus, PACAP may stimulate the synthesis of catecholamines by phosphorylation and activation of tyrosine hydroxylase through Ca2+/calmodulin-dependent and cAMP-dependent protein kinases also in adrenal chromaffin cells.
