Abstract. Perovskite quantum dots have been widely used in light-emitting diodes (LEDs) because of their adjustable color, high quantum yield and easy solution processing. Furthermore, matching energy levels of device plays a profound role in the resultant LEDs. In this study, a polymeric material, namely poly[(9,9-dioctylfluorenyl-2,7-diy)-co-(4,4'-(N-(pbutylphenyl))diphenylamine)] (TFB), is introduced between the quantum dot emission layer and the hole injection layer PEDOT:PSS, which not only prevents the fluorescence quenching caused by the direct contact between the perovskite layer and the hole injection layer, but also reduces hole injection barrier, both being beneficial to the device performance. The optimal thickness of TFB has been obtained by adjusting the rotational speed and precursor solution concentration during spin coating. The optimized quantum dots LED has a switching on voltage of about 2.2 V, a maximum brightness of 4300 cd/m², a maximum external quantum efficiency of 0.15%, and a maximum current density of 0.54 cd/A.

1 Introduction

Owing to their tunable direct bandgap, high optical absorption coefficient, long carrier diffusion length and high defect tolerance, perovskites have been widely attempted in various optoelectronic applications, such as solar cells, light-emitting diodes, lasers and optical detectors. Perovskite quantum dots have been widely reported as emissive materials in LEDs because of their high quantum yield, good monochromaticity (FWHM≈20nm), adjustable color and other advantages. At present, the highest EQEs of three primary RGB colors have exceeded 20%,[9] for red and green and 10% for blue.[9] Compared with OLED and inorganic quantum dot LED, perovskite quantum dots (QDs) possess additional advantages of wide color gamut, simple synthesis method, easily adjustable band gap, low cost and low environmental toxicity.

Generally, to obtain a high-performance LED, besides the optimization of the emissive perovskite materials, it is of highly important to improve the device structure, including the selection of materials for each layer, the matching of energy levels, the wettability, film forming ability and carrier mobility of each layer. LED devices have been developed from simple sandwich structure to a more widely adopted multilayer structure, including anode, hole transport layer (HTL), emitting layer (EML), electron transport layer (ETL) and cathode. Owing to the fact that perovskite QDs were directly spin-coated on top of HTL during device fabrication, the selection and parameter of HTL greatly influence the overall performance of the LEDs. Therefore, if the QDs were directly combined with the HTL material with large energy level difference and inappropriate thickness, fluorescence quenching and low injection efficiency may be resulted.

In this study, Poly[(9,9-dioctylfluorenyl-2,7-diy)-co-(4,4’-(N-(pbutylphenyl))diphenylamine)] (TFB) was introduced as the hole transport layer, the thickness of which would have a profound influence on the device performance. By changing the rotational speed and precursor solution concentration of spin coating, the optimal thickness of 40 nm was obtained. This TFB layer not only reduced the fluorescence quenching, but also optimized the energy level matching and improved the hole injection efficiency. Finally, a quantum dot LED with a turn-on voltage of about 2.2 V, a maximum brightness of 4300 cd/m², a maximum external quantum efficiency of 0.15% and a maximum current density of 0.54 cd/A was obtained.

2 Materials and Methods

2.1 Materials

Poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) was purchased from Heraeus Clevios. Poly[(9,9-dioctylfluorenyl-2,7-diy)-co-(4,4’-(N-(pbutylphenyl))diphenylamine)] (TFB) was purchased from American Dye Source Inc. Poly(methyl methacrylate) (PMMA) (average Mw≈250 000) were purchased from Sigma-Aldrich. Al was purchased from Alfa Aesar. For the
synthesis of ZnO nanoparticles, a 0.5M solution of zinc acetate in dimethyl sulfoxide and 30 mL of tetramethylammonium hydroxide in ethanol were mixed and stirred in ambient air for 1 hour, then washed and dispersed in ethanol. Perovskite quantum dots, FA:CsPbBr₃, were synthesized by the triple-ligand surface engineering according to Song, J., et al.[10] The solvents used in the experiment were purchased from Sigma and used directly.

2.2 Methods

Before the device was fabricated, the indium tin oxide (ITO) /glass substrate (15 Ω / sq) was ultrasonically treated with glass cleaning solution, deionized water, acetone and isopropanol for 15 min in sequence, and then dried with nitrogen flow. After treatment with ultraviolet (UV)-ozone plasma for 15 minutes, PEDOT:PSS was spin-coated onto the ITO substrate (8000rpm/min, 30s) and baked at 150 °C for 15 min under ambient conditions. Then the rest of the process took place in a glove box. Preparation of TFB chlorobenzene solution was carried out by spin-coating on the surface PEDOT:PSS and annealed at 150 °C for 30 min. Then the perovskite quantum dots were spin-coated at 2000 rpm for 2 min and baked at 60 °C for 2 min. Next, a layer of PMMA (the thickness is about 10nm) was spin-coated and annealed at 60 °C, 15min. Subsequently, ZnO was spin-coated followed by annealing at 60 °C for 30 min. Finally, Al were continuously deposited by thermal evaporation under high vacuum.

3 Results and Discussion

![Energy level structure diagram of perovskite quantum dot light-emitting diodes](Figure 1)

The device structure of ITO/PEDOT:PSS/TFB/PVSK/PMAA/ZnO/Al was used to assemble perovskite quantum dot led (PQLED). PQLED is a device that converts the injected electrons and holes into photons through radiation recombination in quantum dots. If the density of injected electron is much larger than that of hole, and most of charge carriers fail to combine into effective electron hole pairs, resulting in low luminous efficiency. In order to balance the hole and electron concentrations at both ends of the quantum dot layer, improve the radiative recombination rate, and improve the luminous efficiency of the device, a hole transport layer and an electron barrier layer have been separately added adjacent to the quantum dot layer. The electron barrier layer consisting of PMMA[14] was aimed to reduce the free electron concentration, while the hole transport layer composed of TFB to facilitate hole injection. The energy level structure is shown in Figure 1. Before adding TFB, the barrier difference between the HOMO energy level of perovskite quantum dots and PEDOT: PSS was 0.5 eV. After adding TFB HTL, the injection loss of holes should be reduced. Besides, the carrier mobility of TFB is $1 \times 10^{-2} \text{cm}^2/\text{v} \cdot \text{s}$, which is more favorable for hole transport compared with PVK ($2.5 \times 10^{-4} \text{cm}^2/\text{v} \cdot \text{s}$)[11] and Poly-TPD ($1 \times 10^{-4} \text{cm}^2/\text{v} \cdot \text{s}$)[12]. The LUMO energy level of TFB is -2.3eV, which could effectively block electron from entering HTL, thus avoiding recombination light emission in the TFB layer and effectively confining electron in perovskite layer.

The precursor solution concentration of TFB was firstly regulated. The chlorobenzene solutions of 4mg/ml, 6mg/ml, 8mg/ml and 10mg/ml TFB were prepared, respectively, followed by spin-coating on top of PEDOT:PSS in a glove box. The performance of the manufactured devices are shown in Figure 2. The tested parameters include current density (J, mA/cm²), luminance (L, cd/m²), external quantum efficiency EQE and current efficiency (CE, cd/A). The current density (J, mA/cm²) is an indication of the leakage current of the device after the voltage is applied. At low voltage, the smaller the current density, the less leakage current. Figure 2(a) shows the current density at different TFB precursor solution concentrations. Two curves corresponding to the TFB solutions with concentration of 6 and 8mg/ml showed less leakage current compared to the rest. Figure 2(b) is the luminance and voltage curve. The turn-on voltages (corresponding voltage when the brightness is 1cd/m²) of different TFB concentrations are 2.5V, 2.3V, 2.2V, and 2.1V, respectively. Figure 2(c) and (d) are the curves of external quantum efficiency and current efficiency versus brightness. Among them, the maximum
The value of EQE and current efficiency were about 0.035%, 0.13cd/A, respectively, both of which corresponded to the TFB concentration of 8mg/ml. The test results are recorded in Table 1.

| TFB Concentration (mg/ml) | 4   | 6   | 8   | 10  |
|---------------------------|-----|-----|-----|-----|
| L max (cd/m²)             | 538 | 674 | 1141| 958 |
| Turn-on Voltage (V)       | 2.5 | 2.2 | 2.3 | 2.1 |
| EQE max (%)               | 0.01| 0.02| 0.035|0.03|
| CE max (cd/A)             | 0.05| 0.07| 0.13| 0.1 |

Subsequently, the rotational speed of TFB has been adjusted by fixing the TFB precursor concentration at 8mg/ml. Specifically, rotational speed of 3000rpm, 3500rpm, 4000rpm, 4500rpm, 5000rpm, 5500rpm, 6000rpm, and 6500rpm have been applied. The corresponding device performances are shown in Figure 3.

| Speed  | L max (cd/m²) | Turn-on Voltage (V) | EQE max (%) | CE max (cd/A) |
|--------|--------------|---------------------|-------------|--------------|
| 3000rpm| 2034         | 2.4                 | 0.08        | 0.31         |
| 3500rpm| 2594         | 2.2                 | 0.09        | 0.32         |
| 4000rpm| 4380         | 2.2                 | 0.15        | 0.54         |
| 4500rpm| 2354         | 2.2                 | 0.06        | 0.20         |
| 5000rpm| 2022         | 2.1                 | 0.05        | 0.19         |
| 5500rpm| 2415         | 2.2                 | 0.08        | 0.30         |
| 6000rpm| 2540         | 2.2                 | 0.06        | 0.22         |
| 6500rpm| 2354         | 2.1                 | 0.06        | 0.21         |

Figure 4(a) shows the picture under natural light just after spin coating of TFB with the optimal combination of precursor concentration and rotational speed. It can be seen from the figure that the film formation is uniform throughout the substrate. Figure 4(b) shows the luminescence diagram of the perovskite quantum dot device after power-on. From the figure, it can be observed that the luminescent area emits uniformly without fluorescence blinking. Figure 4(c) shows the cross-sectional view of the fabricated PQLED. From top to bottom, layers corresponding to ITO, PEDOT: PSS, TFB, PVSK, PMMA, ZnO, and Al can be clearly observed. As shown in the figure, the thicknesses of PEDOT:PSS and PMMA were relatively thin, being about 20nm and 10nm respectively. The thickness of TFB was about 40nm, which is the optimal thickness after adjustment.

Figure 3 (a) shows the current density versus voltage curves at different rotational speeds of TFB precursor. It is found by comparison that when the speed was 4000 rpm, the leakage current was small. Figure 3(b) is the luminance and voltage curve of the perovskite quantum dots LED. When the brightness was 1cd/m², the turn-on voltage corresponding to 4000rpm was 2.2 V. From Figure 3(c) and 3(d), the maximum EQE was about 0.15%, and the maximum CE was about 0.54cd/A, both corresponding to the rotational speed of 4000 rpm. According to the control of concentration and rotational speed, it is found that the perovskite quantum dots LED demonstrated the best device performances when the TFB concentration was 8mg/ml and the rotational speed was 4000rpm. The test results are recorded in Table 2.

Table 2. Various parameters of perovskite quantum dot light-emitting diodes with different rotational speed of TFB precursor solutions.

| Speed  | L max (cd/m²) | Turn-on Voltage (V) | EQE max (%) | CE max (cd/A) |
|--------|--------------|---------------------|-------------|--------------|
| 3000rpm| 2034         | 2.4                 | 0.08        | 0.31         |
| 3500rpm| 2594         | 2.2                 | 0.09        | 0.32         |
| 4000rpm| 4380         | 2.2                 | 0.15        | 0.54         |
| 4500rpm| 2354         | 2.2                 | 0.06        | 0.20         |
| 5000rpm| 2022         | 2.1                 | 0.05        | 0.19         |
| 5500rpm| 2415         | 2.2                 | 0.08        | 0.30         |
| 6000rpm| 2540         | 2.2                 | 0.06        | 0.22         |
| 6500rpm| 2354         | 2.1                 | 0.06        | 0.21         |
4 Conclusion

In summary, we regulated the hole transport layer TFB between the perovskite layer and the hole injection layer PEDOT:PSS to optimize the energy level matching of the overall device. Besides, this additional TFB layer is beneficial to the effective hole injection and able to prevent the fluorescence quenching caused by the direct contact between the perovskite luminescent layer and the hole injection layer. On the other hand, it blocks electrons and avoids recombination of charge carrier in the TFB layer. By adjusting the rotational speed and concentration of the TFB precursor solution, the optimal thickness has been obtained, so that holes passed through effectively, finally recombined with electrons in the perovskite layer to realize effective green light emission. The optimal result of the device is a turn-on voltage of 2.2V, a maximum brightness of 4300 cd/m², a maximum external quantum efficiency of 0.15%, and a maximum current density of 0.54 cd/A. Such results will help the development of perovskite LEDs and lays the foundation for their potential commercial applications.
