In the present study, we attempted to elucidate mechanisms for the regulation of intracellular calcium levels by H2S in primary rat medullary neurons. Our results showed that NaHS significantly increased the level of \([\text{Ca}^{2+}]_i\) in rat medullary neurons in a concentration-dependent manner. L-Cysteine and SAM significantly raised the level of \([\text{Ca}^{2+}]_i\) in the medullary neurons while HA and/or AOAA produced a reversal effect. In addition, L-cysteine and SAM significantly increased but HA and/or AOAA decreased the production of H2S in the cultured neurons. The \([\text{Ca}^{2+}]_i\) elevation induced by H2S was significantly diminished by EGTA-Ca2+-free solutions, and this elevation was also reduced by nifedipine or nimodipine and mibebradil, suggesting the role of L-type and/or T-type Ca2+ channels. Moreover, the effect of H2S on \([\text{Ca}^{2+}]_i\) level in neurons was significantly attenuated by BAPTA-AM and thapsigargin, suggesting the source of Ca2+. Therefore, we concluded that both exogenous and endogenous H2S elevates \([\text{Ca}^{2+}]_i\) level in primarily cultured rat medullary neurons via both increasing calcium influx and mobilizing intracellular Ca2+ stores from ER.

1. Introduction

Hydrogen sulfide (H2S) is an important gasotransmitter along with nitric oxide (NO), carbon monoxide (CO), and ammonium in addition to its conventional toxicological profile [1–3]. The endogenous production of H2S in the human body is catalyzed by several enzymes, including two pyridoxal-5'-phosphate (PLP-) dependent enzymes, namely, cystathionine-\(\beta\)-synthase (CBS) and cystathionine-\(\gamma\)-lyase (CSE), and 3-mercaptopyruvatesulfurtransferase (MST) [4]. L-Cysteine and homocysteine or their derivatives are the substrates of these H2S-generating enzymes [4]. The expression of these H2S-generating enzymes is tissue specific. CBS is highly expressed in the central nervous system (CNS). CSE is mainly expressed in the cardiovascular system [2] and MST is considered as another source of H2S in the brain [5]. The physiological concentration of sulfide in brain tissue is detected to be 50–160 \(\mu\)M [6], whereas the blood level of H2S is estimated at low micromolar to high nanomolar range [7].

H2S is a signaling molecule for neurotransmission and neuromodulation and is involved in learning, memory, and nociception [3]. H2S has been reported to enhance the induction of long-term potentiation (LTP), a synaptic model in learning and memory, and increase the sensitivity of NMDA receptor mediated response, indicating a neuroprotective effect of H2S on homocysteine-induced cerebrovascular pathology [8, 9]. NaHS attenuated the inflammation induced by LPS in microglia via inhibiting of p38-MAPK [10], suggesting the implication of H2S in the neuroprotection or treatment of cerebral ischemia and neuroinflammatory diseases. It was also found that H2S decreased blood pressure in various models of hypertension [11–14]. H2S treatment reduced blood pressure and oxidative stress in angiotensin II induced hypertensive mice [15] and in spontaneously
hypertensive rats (SHRs) [14]. These findings indicate that H$_2$S, as an important neuromodulator, produces antineuroinflammatory, antioxidant, and antiapoptotic effects in neurons and glial cells. However, the underlying mechanisms are still unsettled.

Calcium is second messenger for neuronal functions, such as release of neurotransmitters [16], synaptic plasticity [17, 18], neuronal excitation, and gene transcription [16]. Changes of intracellular free Ca$^{2+}$ concentration ([Ca$^{2+}$]$_i$) may directly alter neuron excitability [19]. It was reported that H$_2$S increased [Ca$^{2+}$]$_i$, and induced Ca$^{2+}$ waves in primary cultures of astrocytes [20] and regulated calcium homeostasis in microglial cells [21]. Another study showed that H$_2$S modulated calcium homeostasis in cultured rat cerebellar granule neurons (CGN) as it induced activation of Ca$^{2+}$ entry through L-type Ca$^{2+}$ channels and thereby of neuronal activity [22]. It has also been reported that H$_2$S increased [Ca$^{2+}$]$_i$ in SH-SY5Y neuronal cells by increasing Ca$^{2+}$ influx via plasma membrane and the subsequent release of calcium from intracellular calcium store [19]. However, the regulation of H$_2$S on [Ca$^{2+}$]$_i$ in the medullary neurons has not been demonstrated.

We recently reported that H$_2$S exerts its cardiovascular effects by decreasing oxidative stress via inhibition of NADPH oxidase activity in the rostral ventrolateral medulla (RVLM) of SHRs [14]. RVLM, where sympathetic premotor neurons are located, is connected with other cardiovascular nuclei in the CNS, functioning to regulate cardiovascular effects by regulating sympathetic nerve activity [23–25]. However, the molecular mechanisms for the neumodulatory effect of H$_2$S on RVLM are not clear. In the present study, we used the primarily cultured medullary neurons to investigate the effects of H$_2$S on the level of [Ca$^{2+}$]$_i$. Our study provides the evidence that H$_2$S increases [Ca$^{2+}$]$_i$, in neurons through several different mechanisms.

### 2. Materials and Methods

#### 2.1. Chemicals

DMEM/F-12, neurobasal medium, and B27 supplement were obtained from Gibco Invitrogen Corporation (Carlsbad, CA, USA). Fura-2 AM and BAPTA-AM were obtained from Dojindo Molecular Technologies, Inc. Sodium hydrosulfide hydrate (NaHS), EGTA, thapsigargin (TG), nifedipine, nimodipine, and mibefradil were obtained from Sigma-Aldrich. Fura-2 AM and TG were dissolved in dimethyl sulfoxide (DMSO). The final concentration of TG, nifedipine, nimodipine, and mibefradil was 20 μg/mL. Sodium hydrosulfide hydrate (NaHS) [pH 7.3] at 37°C for 30 min after being washed three times with D-hanks’ solution. D-Hanks solution was added to the cell cultures for confocal microscopy (Zeiss LSM510, Jena, Germany).

#### 2.2. Cell Cultures

Primary cultures of medullary neurons were prepared from 14-day-old embryos of Sprague Dawley rats. The fetal rats were humanely taken out and killed by decapitation, and then brain slices containing the entire medulla were prepared. The dissected tissues were removed and transferred to D-hanks’ solution containing (in g/L) 8.0 NaCl, 0.4 KCl, 0.134 Na$_2$HPO$_4$, 12H$_2$O, 0.06 KH$_2$PO$_4$, 0.35 NaHCO$_3$, and 1 glucose, pH 7.2–7.4, and finally chopped. The tissues were then treated with 0.125% trypsin in D-hanks’ solution for 10–12 min at 37°C and gently triturated using flame-polished Pasteur pipettes. Cell suspension was centrifuged for 8 min at 1000 xg. Then the cell pellets were resuspended in Dulbecco’s modified Eagle’s medium (DMEM) and F-12 supplement (1:1) with 10% fetal bovine serum (FBS) before placing onto glass-bottomed dishes coated with poly-L-lysine (20 μg/mL for 12–24 h) and kept at 37°C in 5% CO$_2$ incubator. After overnight incubation in DMEM, the medium was changed to neurobasal medium (Gibco) containing 15 mM glucose supplemented with 2% B27, 2 mM glutamine, 10 μg/mL penicillin, and 10 μg/mL streptomycin. The culture medium for medullary neurons was changed every 48 h. Microscopically, glial cells were not apparent in medullary neurons employing this protocol. The neurons were maintained for 7–10 days in primarily culture until used for calcium imaging.

#### 2.3. Immunofluorescence Staining and Laser Confocal Microscopy

The primarily cultured medullary neurons were washed three times with D-hanks’ solution and then cells were fixed with 1 mL 4% paraformaldehyde (PFA) in 0.1 M sodium phosphate buffer (0.1 M PB; pH 7.4) for 20 min. Afterward, cells were blocked with 1 mL 5% fetal bovine serum (FBS) for 30 min after being washed three times with D-hanks’ solution. Then, cells were incubated with primary antibodies, namely, anti-MAP-2 (mouse, 1: 200) and anti-glutamate (rabbit, 1: 100), anti-MAP-2 antibody (rabbit, 1: 200) and anti-CBS antibody (mouse, 1: 100), anti-MAP-2 antibody (mouse, 1: 200) and anti-MST (rabbit, 1: 50), and anti-MAP-2 antibody (rabbit, 1: 200) and anti-CSE (mouse, 1: 50), for 1 h at 37°C, plus an additional 12 h at 4°C. On the next day, the cell were washed three times with D-hanks’ solution and incubated with fluorescent secondary antibodies, namely, FITC goat anti-rabbit IgG (H+L) (1: 100) and Cy3 goat anti-mouse IgG (H+L) (1: 100) or Alexa Flour 488 goat anti-rabbit IgG (H+L) (1: 500) and Alexa Flour 594 goat anti-mouse IgG (H+L) (1: 500) for 1 h at 37°C. Then cells were incubated with DAPI for 5 min at 37°C after being washed three times with D-hanks’ solution. Finally, 500 μL D-hanks’ solution was added to the cell dishes for confocal microscopy.

#### 2.4. [Ca$^{2+}$]$_i$, Measurements

To determine the level of [Ca$^{2+}$]$_i$, neurons were loaded with Ca$^{2+}$-specific dye Fura-2 by incubating with 2.5 μM Fura-2/AM (Molecular Probes) in HBSS (140 mM NaCl, 5 mM KCl, 1 mM MgCl$_2$, 2 mM CaCl$_2$, 10 mM glucose, and 10 mM HEPES-NaHS [pH 7.3]) at 37°C for 30 minutes and subsequently washed three times with HBSS to remove the excess extracellular Fura-2/AM. [Ca$^{2+}$]$_i$ was
expressed as the ratio (R) of emitted fluorescence corresponding to excitation wavelengths of 340 nm and 380 nm. R/R₀ was applied to assess the change of [Ca²⁺] level, in which R₀ represents the fluorescent signal before drug treatment and R represents the signal after drug treatment.

To identify the source of Ca²⁺, the increase in [Ca²⁺] induced by NaHS was determined in Ca²⁺-free HBSS containing the extracellular Ca²⁺ chelator EGTA (2 mM). In addition, separate cultures were treated with two selective L-type Ca²⁺ channel blockers, nifedipine (10 μM) and nimodipine (10 μM), and with the selective T-type Ca²⁺ channel inhibitor mibebradil (2 μM). To determine the involvement of intracellular Ca²⁺ stores in neurons, the cultures were treated with the intracellular Ca²⁺-chelating agent BAPTA-AM (50 μM) and thapsigargin (1 μM) with NaHS (200 μM) stimulation. Thapsigargin is known to release Ca²⁺ from the endoplasmic reticulum by inhibiting Ca²⁺ ATPase. All experiments were carried out at 37 °C and were repeated 4–6 times using different batches of cells.

2.5. Cell Viability Assay. Cell viability was analyzed by using Cell Counting Kit-8 (CCK-8, obtained from Dojindo). CCK-8 allows sensitive colorimetric assays for the determination of cell viability in cell proliferation and cytotoxicity assays. Dojindo’s highly water-soluble tetrazolium salt, WST-8, is dojindo’s highly water-soluble tetrazolium salt, WST-8, is Dojindo’s highly water-soluble tetrazolium salt, WST-8, is Dojindo’s highly water-soluble tetrazolium salt, WST-8, is Dojindo’s highly water-soluble tetrazolium salt, WST-8, is directly proportional to the number of living cells. The primary medullary neurons were cultured in 96-well plates at a cellular density of 0.5 × 10⁴ cells/well. Cells were cultured for 6–7 days at 37 °C in 5% CO₂ incubator. On the following day, the cultured neurons were treated for 30 min with different concentrations of NaHS. Afterward, each well of plates was added to 10 μL CCK-8 solution and then incubated at 37 °C, 5% CO₂ for 2 h. Subsequently, the cell viability was assessed by measuring the absorbance at 450 nm.

2.6. Measurement of H₂S Production. H₂S levels in primarily cultured neurons were measured according to previously described methods with some modifications [26]. Briefly, primarily cultured medullary neurons were homogenized in ice-cold Tris-HCl (100 mM, pH 8.5) followed by centrifugation at 12,000 g for 20 min at 4 °C. Thirty μL supernatant was incubated with 80 μL monobromobimane (MBB) for 40 min on a shaker at room temperature. Reaction was terminated by adding 20% formic acid and the level of H₂S was tested by Gas Chromatograph-Mass Spectrometer (GC-MS). Proteins in the supernatant were quantified using BCA reagent (Shen Neng Bo Cai Corp.). H₂S concentrations were determined using a curve generated with sodium sulfide (0–40 μM) standards, and the H₂S concentrations in cultured cells were expressed as μM. H₂S concentrations in primarily cultured medullary neurons were divided by the protein concentrations and were expressed as μmol/g of protein.

2.7. Statistical Analysis. Statistical significance was determined using independent t-test or one-way ANOVA followed by SPSS 19.0. Data are presented as mean ± SEM. Difference at the P < 0.05 level was considered statistically significant.

3. Results

3.1. CBS and MST Were Expressed in the Medullary Neurons. The primarily cultured medullary neurons were stained with anti-MAP-2 (red, Figure 1(a)) and anti-Glutamate (green, Figure 1(b)), suggesting that more than 90% of cells cultured were medullary neurons and most of them were glutamate positive neurons (Figure 1(d)). Double-immunofluorescence labeling was used to study the specific localization of CBS in the primary medullary neurons. Fluorescence micrograph of neurons showed that neurons were stained with anti-MAP-2 antibody (green, Figure 1(e)). Anti-CBS was also stained with neurons (red, Figure 1(f)), and the merge of double-immunofluorescence labeling showed that more than 80% of neurons cultured were expressed with CBS (Figure 1(h)).

As MST is considered as another source of H₂S in the brain [5], we also studied the expression of MST. Fluorescence micrograph of neurons showed that neurons were stained with anti-MAP-2 antibody (red, Figure 1(i)). Anti-MST was also stained with neurons (green, Figure 1(j)), and the merge of double-immunofluorescence labeling showed that MST was also expressed in the medullary neurons (Figure 1(l)).

As CSE is another mainly source of H₂S, we also studied the expression of CSE. Fluorescence micrograph of neurons showed that neurons were stained with anti-MAP-2 antibody (green, Figure 1(m)), while anti-CSE was negatively stained with neurons (red, Figure 1(n)), and the merge of double-immunofluorescence labeling showed that CSE was negatively expressed in the primarily cultured medullary neurons (Figure 1(p)).

3.2. Effect of Exogenous H₂S on [Ca²⁺] in the Primary Medullary Neurons. NaHS, a H₂S donor, at 200 μM induced a significant [Ca²⁺] increase in neurons and the effect of NaHS occurred rapidly and reached a peak within 10 min after administration. The level of [Ca²⁺], started to decline after washout (Figure 2(a)). NaHS (50–300 μM) significantly increased the level of [Ca²⁺], in the medullary neurons in a concentration-dependent manner (Figures 2(b) and 2(c)). Moreover, the increase in [Ca²⁺] level induced by NaHS is persistent. We also examined cell viability after adding NaHS using CCK-8 assay. As shown in Figure 2(d), there was no significant difference in the cell viability between Control and the groups treated by NaHS at 50–300 μM for 30 min. These data suggested that exogenous H₂S could increase [Ca²⁺] level in medullary neurons, while the elevation of [Ca²⁺] induced by NaHS was not due to or caused by the cytotoxicity of NaHS.
Figure 1: Identification of glutamate positive neurons ((a), (b), (c), and (d)) and the expression of CBS ((e), (f), (g), and (h)), MST ((i), (j), (k), and (l)), and CSE ((m), (n), (o), and (p)) in the rat primary medullary neurons. Confocal images showed that fluorescence micrograph of neurons stained with anti-MAP-2 antibody ((a), (e), (i), and (m), a neuronal maker), anti-glutamate antibody (b), anti-CBS antibody (f), anti-MST antibody (j), anti-CSE antibody (n), DAPI ((c), (g), (k), and (o)), or the merge of the other 3 photos ((d), (h), (l), and (p)). Scale bar = 50 μm.

3.3. Effect of Endogenous H$_2$S on [Ca$^{2+}$]$_i$ in the Primary Medullary Neurons. To investigate the endogenous H$_2$S n [Ca$^{2+}$], in the primary medullary neurons, we applied L-cysteine (a substrate for H$_2$S), SAM (a CBS activator), and HA and AOAA (two CBS inhibitors), respectively. The results showed that L-cysteine and SAM significantly raised the level of [Ca$^{2+}$]$_i$ in the medullary neurons (Figures 3(a) and 3(b)) while HA and/or AOAA produced a reversal effect (Figures 3(c) and 3(d)). And HA or AOAA can no longer inhibit [Ca$^{2+}$]$_i$ level in the presence of SAM. However, the stimulatory effect of SAM on [Ca$^{2+}$]$_i$ was not affected by HA or AOAA (Figure 3(d)). In addition, L-cysteine and
3.4. The Evolvement of L-Type and T-Type Ca\(^{2+}\) Channels in the Effect of H\(_2\)S. In order to determine the source of increased [Ca\(^{2+}\)]\(_i\) in NaHS-stimulated medullary neurons, the cells were bathed either in Ca\(^{2+}\)-free HBSS (containing 2 mM EGTA) or in normal HBSS. Similar to the data shown in Figures 2(a) and 2(b), NaHS at 200 \(\mu\)M caused a robust increase in [Ca\(^{2+}\)]\(_i\) within 10 min after incubation of normal Ca\(^{2+}\) containing HBSS (Figure 5(a)). This effect was partly abolished in cells bathed in Ca\(^{2+}\)-free HBSS (Figures 5(a) and 5(e)).

As shown in Figures 5(b) and 5(c), both nifedipine (10 \(\mu\)M) and nimodipine (10 \(\mu\)M), two L-type Ca\(^{2+}\) channel blockers, significantly suppressed the effect of NaHS at 200 \(\mu\)M (Figures 5(b), 5(c), and 5(e)). A selective T-type Ca\(^{2+}\) channel inhibitor, mibefradil (2 \(\mu\)M), also inhibited the elevation of [Ca\(^{2+}\)]\(_i\) level induced by NaHS (Figures 5(d) and 5(e)).

3.5. The Involvement of Intracellular Ca\(^{2+}\) Stores in the Effect of H\(_2\)S. The neurons were treated with BAPTA-AM (an intracellular Ca\(^{2+}\) chelator) and thapsigargin (a sarco/endoplasmic reticulum Ca\(^{2+}\)-ATPase blocker) with or without NaHS. The effect of NaHS on [Ca\(^{2+}\)]\(_i\) level in neurons was significantly attenuated by depletion of BAPTA-AM (50 \(\mu\)M, Figures 6(a) and 6(c)) and thapsigargin (TG, 1 \(\mu\)M, Figures 6(b) and 6(c)).

4. Discussion

In the present study, we attempted to elucidate mechanisms for the regulation of intracellular calcium levels by H\(_2\)S in...
Figure 3: The effect of endogenous H$_2$S on the [Ca$^{2+}$]$_i$ level in the primarily cultured medullary neurons. (a) Typical elevation of [Ca$^{2+}$]$_i$ induced by L-cysteine (the H$_2$S precursor) at 1 mM. (b) Typical effects of SAM (an activator of CBS) at 200 $\mu$M on [Ca$^{2+}$]$_i$ level. (c) Typical effects of HA (an inhibitor of CBS) at 10 mM on [Ca$^{2+}$]$_i$ level. (d) Group data showed the effects of endogenous H$_2$S on the [Ca$^{2+}$]$_i$ level. AOAA (another inhibitor of CBS). *$P$ < 0.05, **$P$ < 0.01 versus Control group; $n$ = 6 in each group.

Figure 4: The production of H$_2$S in the primarily cultured medullary neurons treated by L-cysteine (1 mM), SAM (200 $\mu$M), HA (10 mM), and AOAA (10 mM), respectively. *$P$ < 0.05; **$P$ < 0.01. $n$ ≥ 7 in each group.
Figure 5: The effect of NaHS on $[\text{Ca}^{2+}]_i$, in the primarily cultured medullary neurons in Ca$^{2+}$-free solution or in the presence of L-type and/or T-type Ca$^{2+}$ channels inhibitors. ((a)–(c)) Typical suppression of $[\text{Ca}^{2+}]_i$ level induced by NaHS in EGTA-treated Ca$^{2+}$-free solution (a) or in normal Ca$^{2+}$ containing HBSS with or without nifedipine (10 μM, (b)), nimodipine (10 μM, (c)), and mibefradil (2 μM, (d)). (e) Group data showed that the effects of NaHS were attenuated by EGTA-Ca$^{2+}$-free solution and suppressed by nifedipine, nimodipine, or mibefradil. **P < 0.01 versus Control; *P < 0.05 versus NaHS group; ##P < 0.01 versus NaHS group. n = 5 in each group.
primary rat medullary neurons. The results provide the evidence for the first time on the primarily cultured medullary neurons that H$_2$S elevates [Ca$^{2+}$]$_i$ level via both increasing calcium influx and mobilizing intracellular Ca$^{2+}$ stores from ER. Our conclusion is supported by the following findings: firstly, NaHS significantly increased the level of [Ca$^{2+}$]$_i$ in rat medullary neurons in a concentration-dependent manner. Secondly, L-cysteine and SAM significantly raised the level of [Ca$^{2+}$]$_i$ in the medullary neurons while HA and/or AOAA produced a reversal effect. In addition, L-cysteine and SAM significantly increased but HA and/or AOAA decreased the production of H$_2$S in the cultured neurons. Thirdly, the Ca$^{2+}$ elevation induced by H$_2$S was significantly diminished by EGTA-Ca$^{2+}$-free solutions, and this elevation was also reduced by nifedipine or nimodipine (an antagonist of L-type Ca$^{2+}$ channel) and mibebradil (an antagonist of T-type Ca$^{2+}$ channel), suggesting the role of L-type and/or T-type Ca$^{2+}$ channels. Lastly, the effect of H$_2$S on [Ca$^{2+}$]$_i$ level in neurons was significantly attenuated by BAPTA-AM (an intracellular Ca$^{2+}$ chelator, 50 μM) and thapsigargin (a sarco/endoplasmic reticulum Ca$^{2+}$-ATPase blocker, 1 μM), suggesting the source of Ca$^{2+}$.

Previous studies have demonstrated the crucial role of H$_2$S homeostasis in hypertension. Administration of H$_2$S donors and precursors decreases mean blood pressure in various hypertensive models (chronic inhibition of nitric oxide synthase, two-kidney-one-clip, and SHRs) [11–13, 27]. One of the molecular targets for the cellular effect of H$_2$S is K$_{ATP}$ channels [28]. It has been reported that H$_2$S in the RVLM inhibits sympathetic vasomotor tone through opening K$_{ATP}$ channels [29, 30]. We have shown that H$_2$S in RVLM suppressed the blood pressure in SHRs [14]. The signaling mechanisms in the CNS of the antihypertensive effect of H$_2$S have not been elucidated. On the other hand, the antihypertensive effects of H$_2$S in the caudal ventrolateral medulla (CVLM) involved K$_{ATP}$ channels and glutamic acid receptor [31, 32]. Glutamate acid has been suggested to be
an important neurotransmitter in antihypertensive effects of \( \text{H}_2\text{S} \). In order to provide more evidence for the regulation of \( \text{H}_2\text{S} \) on the cardiovascular effects, we mainly focused on the medullary neurons in vivo. To ensure the cultured medullary cells were the target neurons which were glutamate positive neurons, we demonstrated that glutamate was coexpressed in more than 90% of primarily cultured medullary neurons. \( \text{H}_2\text{S} \) is mainly produced endogenously by CBS and MST in the CNS [4, 5] and CBS is mainly expressed in the hippocampus and cerebellum, as well as the cerebral cortex and brain stem [8]. Our previous study has shown that CBS immunoreactivity was found in the rostral ventrolateral medulla (RVLM) neurons in vivo and the level of CBS proteins in the RVLM was lower in SHR's than in WKY rats [14]. In this study, our results showed that more than 80% of cultured medullary neurons were glutamate positive neurons, and CBS and MST were, respectively, expressed in these neurons in vitro, while the expression of CSE was negative in these primarily cultured medullary neurons. These results provided the basis of study of \( \text{H}_2\text{S} \).

Calcium plays an important role in regulating a great variety of neuronal processes such as release of neurotransmitters, synaptic plasticity, neuronal excitation, and gene transcription. It was reported that \( \text{H}_2\text{S} \) increased [\( \text{Ca}^{2+} \)]\( _i \), in SH-SY5Y neuronal cells by increasing \( \text{Ca}^{2+} \) influx via plasma membrane and in turn releasing calcium from intracellular calcium store [19]. Exerting its function as a gaseous transmitter, \( \text{H}_2\text{S} \) regulates calcium homeostasis in neurons via both increasing calcium influx and mobilizing calcium from ER [19]. In CNS, \( \text{H}_2\text{S} \) activates L-type \( \text{Ca}^{2+} \) channels in rat cerebellar granule neurons to increase calcium signals which were inhibited by nifedipine and nimodipine [33] and in hippocampal slices and microglia to induce hippocampal LTP and \( \text{Ca}^{2+} \) waves in astrocytes [20]. \( \text{H}_2\text{S} \) also activates T-type \( \text{Ca}^{2+} \) channels in NGIO8-15 (neuroblastoma cell line) involved in neuronal differentiation [34] and activates TRPA1 channels in rat sensory neurons from dorsal root ganglion [35]. The regulation of \( [\text{Ca}^{2+}]_i \), in the medullary neurons by \( \text{H}_2\text{S} \) has not been reported. Our results showed that NaHS (50–300 \( \mu \)M) significantly increased the level of \( [\text{Ca}^{2+}]_i \), in rat medullary neurons in a concentration-dependent manner. On the other hand, L-cysteine and SAM significantly raised the level of \( [\text{Ca}^{2+}]_i \), in the medullary neurons while HA and/or AOAA produced a reversal effect. Meanwhile, HA or AOAA can no longer inhibit \( [\text{Ca}^{2+}]_i \), level in the presence of SAM. However, the stimulatory effect of SAM on \( [\text{Ca}^{2+}]_i \), was not affected by HA or AOAA. The possible reasons may be considered as follows: on the one hand, the affinity of SAM to CBS is much greater than that of HA or AOAA so that the stimulatory effect of SAM is dominating; on the other hand, the possibility that the increasing effects of L-cysteine and SAM on \( [\text{Ca}^{2+}]_i \) may be a \( \text{H}_2\text{S} \)-independent manner is not ruled out and is needed to be addressed in the future. In addition, L-cysteine and SAM significantly increased the production of \( \text{H}_2\text{S} \) in the cultured neurons and HA and/or AOAA decreased the production of \( \text{H}_2\text{S} \). These results suggested that both exogenous \( \text{H}_2\text{S} \) and endogenous \( \text{H}_2\text{S} \) increase the level of \( [\text{Ca}^{2+}]_i \), in the medullary neurons.

[\( \text{Ca}^{2+}]_i \) is controlled by \( \text{Ca}^{2+} \) channels in the membrane and intracellular \( \text{Ca}^{2+} \) stores [36]. The changes of \( [\text{Ca}^{2+}]_i \) due to extracellular \( \text{Ca}^{2+} \) influx may be facilitated by voltage-gated channels, transmitter-gated \( \text{Ca}^{2+} \) permeant ion channels, transient receptor potential (TRP) ion channels, and \( \text{Ca}^{2+} \) pumps located in the plasma membrane [1, 36]. The function of status of intracellular \( \text{Ca}^{2+} \) stores is controlled by ryanodine receptor (RyR) channels, inositol triphosphate receptor (IP3R) channels, and sarcodoplasmic reticular \( \text{Ca}^{2+} \) ATPases (SERCA) [1, 36]. In order to determine the source of \( [\text{Ca}^{2+}]_i \), in NaHS-stimulated medullary neurons, we applied to the EGTA-\( \text{Ca}^{2+} \)-free solution and BAPTA-AM to chelate the extracellular \( \text{Ca}^{2+} \) and intracellular \( \text{Ca}^{2+} \), respectively. The results showed that the \( \text{Ca}^{2+} \) elevation induced by \( \text{H}_2\text{S} \) was significantly diminished by EGTA-\( \text{Ca}^{2+} \)-free solutions and/or BAPTA-AM, suggesting that the elevation of \( [\text{Ca}^{2+}]_i \) level in medullary neurons partly involved both an influx of extracellular \( \text{Ca}^{2+} \) and the intracellular \( \text{Ca}^{2+} \) stores. That thapsigargin (a sarco/endoplasmic reticulum \( \text{Ca}^{2+} \)-ATPase blocker) significantly attenuates the effect of \( \text{H}_2\text{S} \) on \( [\text{Ca}^{2+}]_i \) level in neurons further suggests that NaHS releases calcium from intracellular \( \text{Ca}^{2+} \) stores.

In summary, the present study demonstrates that both exogenous \( \text{H}_2\text{S} \) and endogenous \( \text{H}_2\text{S} \) elevate \( [\text{Ca}^{2+}]_i \), level in primarily cultured rat medullary neurons via both increasing calcium influx and mobilizing intracellular \( \text{Ca}^{2+} \) stores from ER.
