A Simple Optimal Binary Representation of Mosaic Floorplans and Baxter Permutations

Bryan Dawei He*

Abstract

A floorplan is a rectangle subdivided into smaller rectangular sections by horizontal and vertical line segments. Each section in the floorplan is called a block. Two floorplans are considered equivalent if and only if there is a one-to-one correspondence between the blocks in the two floorplans such that the relative position relationship of the blocks in one floorplan is the same as the relative position relationship of the corresponding blocks in another floorplan. The objects of Mosaic floorplans are the same as floorplans, but an alternative definition of equivalence is used. Two mosaic floorplans are considered equivalent if and only if they can be converted to each other by sliding the line segments that divide the blocks.

Mosaic floorplans are widely used in VLSI circuit design. An important problem in this area is to find short binary string representations of the set of \(n\)-block mosaic floorplans. The best known representation is the Quarter-State Sequence which uses \(4n\) bits. This paper introduces a simple binary representation of \(n\)-block mosaic floorplan using \(3n - 3\) bits. It has been shown that any binary representation of \(n\)-block mosaic floorplans must use at least \((3n - o(n))\) bits. Therefore, the representation presented in this paper is optimal (up to an additive lower order term).

Baxter permutations are a set of permutations defined by prohibited subsequences. Baxter permutations have been shown to have one-to-one correspondences to many interesting objects in the so-called Baxter combinatorial family. In particular, there exists a simple one-to-one correspondence between mosaic floorplans and Baxter permutations. As a result, the methods introduced in this paper also lead to an optimal binary representation of Baxter permutations and all objects in the Baxter combinatorial family.

1 Introduction

In this section, we introduce the definition of mosaic floorplans and Baxter permutations, describe their applications and previous work in this area, and state our main result.

1.1 Floorplans and Mosaic Floorplans

Definition 1 A floorplan is a rectangle subdivided into smaller rectangular subsections by horizontal and vertical line segments such that no four subsections meet at the same point.

*Department of Computer Science, California Institute of Technology, Pasadena, CA 91125. Email: bryanhe@caltech.edu
The smaller rectangular subsections are called blocks. Figure 1 shows three floorplans, each containing 9 blocks. Note that the horizontal and vertical line segments do not cross each other. They can only form T-junctions (可以更好, ⊥, ⊣, and ⊤).

The definition of equivalent floorplans does not consider the size of the blocks of the floorplan. Instead, two floorplans are considered equivalent if and only if their corresponding blocks have the same relative position relationships. The formal definition is given below.

**Definition 2** Let $F_1$ be a floorplan with $R_1$ as its set of blocks. Let $F_2$ be another floorplan with $R_2$ as its set of blocks. $F_1$ and $F_2$ are considered equivalent floorplans if and only if there is a one-to-one mapping $g : R_1 \rightarrow R_2$ such that the following conditions hold:

1. For any two blocks $r, r' \in R_1$, $r$ and $r'$ share a horizontal line segment as their common boundary with $r$ above $r'$ if and only if $g(r)$ and $g(r')$ share a horizontal line segment as their common boundary with $g(r)$ above $g(r')$.

2. For any two blocks $r, r' \in R_1$, $r$ and $r'$ share a vertical line segment as their common boundary with $r$ to the left of $r'$ if and only if $g(r)$ and $g(r')$ share a vertical line segment as their common boundary with $g(r)$ to the left of $g(r')$.

In Figure 1 (a) and (b) have the same number of blocks and the position relationships between their blocks are identical. Therefore, (a) and (b) are equivalent floorplans. However, (c) is not equivalent to either.

The objects of mosaic floorplans are the same as the objects of the floorplans. However, mosaic floorplans use a different definition of equivalence. Informally speaking, two mosaic floorplans are considered equivalent if and only if they can be converted to each other by sliding the horizontal and vertical line segments. The equivalence of the mosaic floorplans is formally defined by using the horizontal constraint graph and the vertical constraint graph. The horizontal constraint graph describes the horizontal relationship between the vertical line segments of a floorplan. The vertical constraint graph describes the vertical relationship between the horizontal line segments of a floorplan. The formal definitions are given below.

**Definition 3** Let $F$ be a floorplan.

1. The horizontal constraint graph $G_H(F)$ of $F$ is a directed graph. The vertex set of $G_H(F)$ 1-to-1 corresponds to the set of the vertical line segments of $F$. For two vertices $u_1$ and $u_2$ in
there is a directed edge $u_1 \rightarrow u_2$ if and only if there is a block $b$ in $F$ such that the vertical line segment $v_1$ corresponding to $u_1$ is on the left boundary of $b$ and the vertical line segment $v_2$ corresponding to $u_2$ is on the right boundary of $b$.

2. The vertical constraint graph $G_V(F)$ of $F$ is a directed graph. The vertex set of $G_V(F)$ 1-to-1 corresponds to the set of the horizontal line segments of $F$. For two vertices $u_1$ and $u_2$ in $G_H(F)$, there is a directed edge $u_1 \rightarrow u_2$ if and only if there is a block $b$ in $F$ such that the horizontal line segment $h_1$ corresponding to $u_1$ is on bottom boundary of $b$ and the horizontal line segment $h_2$ corresponding to $u_2$ is on the top boundary of $b$.

The graphs in Figure 2 are the constraint graphs of all three floorplans shown in Figure 1 (a), (b), and (c). Note that the bottom (top, left, right, respectively) boundary of the floorplan is represented by the south (north, west, east, respectively) vertex labeled by $S$ ($N$, $W$, $E$, respectively) in the constraint graphs. Also note that each edge in $G_V(F)$ ($G_V(F)$, respectively) corresponds to a block in the floorplan.

![Diagram](image)

Figure 2: The constraint graphs representing all three mosaic floorplans in Figure 1 (a) is the horizontal constraint graph. (b) is the vertical constraint graph.

**Definition 4** Two mosaic floorplans are equivalent mosaic floorplans if and only if they have identical horizontal constraint graphs and vertical constraint graphs.

Thus all three floorplans shown in Figure 1 (a), (b), and (c) are equivalent mosaic floorplans. Note that the floorplan in Figure 1 (c) is obtained from the floorplan in Figure 1 (b) by sliding the horizontal line segment between the blocks $g$ and $d$ downward; the horizontal line segment between the blocks $f$ and $c$ upward; the vertical line segment between the blocks $a$ and $b$ to the right.

### 1.2 Applications of Floorplans and Mosaic Floorplans

Floorplans and mosaic floorplans are used in the first major stage (called floorplanning) in the physical design cycle of VLSI (Very Large Scale Integration) circuits [10]. The blocks in a floorplan correspond to the components of a VLSI chip. The floorplanning stage is used to plan the relative position of the circuit components. At this stage, the blocks do not have specific sizes assigned to them yet. So only the position relationship between the blocks are considered.

For a floorplan, the wires between two blocks run cross their common boundary. In this setting, two equivalent floorplans provide the same connectivity between blocks. For a mosaic floorplan,
the line segments are the wires. Any block with a line segment on its boundary can be connected to
the wires represented by the line segment. In this setting, two equivalent mosaic floorplans provide
the same connectivity between blocks.

One of the main problems in this area is to find a short binary representation of floorplans
and mosaic floorplans. These representations are used by various algorithms to generate floorplans
in order to solve various VLSI layout optimization problems. Shorter representation allows more
efficient optimization algorithms.

1.3 Baxter Permutations

Baxter permutations are a set of permutations defined by prohibited subsequences. They were
first introduced in [3]. It was shown in [8] that the set of Baxter permutations has one-to-one
correspondences to many interesting objects in the so-called Baxter combinatorial family. For
examples, [4] showed that plane bipolar orientations with \( n \) edges have a one-to-one correspondence
with Baxter permutations of length \( n \). [5] establishes a relationship between Baxter permutations
and pairs of alternating sign matrices.

In particular, it was shown in [1, 6, 18] that mosaic floorplans are one of the objects in the Baxter
combinatorial family. A simple and efficient one-to-one correspondence between mosaic floorplans
and Baxter permutations was established in [1, 6]. As a result, any binary representation of mosaic
floorplans can also be converted to a binary representation of Baxter permutations.

1.4 Previous Work on Representations of Floorplans and Mosaic Floorplans

Because of their applications in VLSI physical design, the representations of floorplans and mosaic
floorplans have been studied extensively by mathematicians, computer scientists and electrical
engineers. Although their definitions are similar, the combinatorial properties of floorplans and
mosaic floorplans are quite different. The following is a partial list of previous research on floorplans
and mosaic floorplans.

Floorplans:

There is no known formula for calculating \( F(n) \), the number of \( n \)-block floorplans. The first
few values of \( F(n) \) (starting from \( n = 1 \)) are \{1, 2, 6, 24, 116, 642, 3938, ... \}. Researchers have
been trying to bound the range of \( F(n) \). In [2], it was shown that there exists a constant \( c =
\lim_{n \to \infty} (F(n))^{1/n} \) and \( 11.56 < c < 28.3 \). This means that \( 11.56^n \leq F(n) \leq 28.3^n \) for large \( n \). The
upper bound of \( F(n) \) is reduced to \( F(n) \leq 13.5^n \) in [7].

Algorithms for generating floorplans were presented in [12]. In [16], a \((5n-5)\)-bit binary string
representation of \( n \)-block floorplans was found. A different \( 5n \)-bit binary string representation of
\( n \)-block floorplans was presented in [17]. The shortest known binary string representation of \( n \)-block
floorplans was given in [15]. This representation uses \((4n-4)\) bits.

Since \( F(n) \geq 11.56^n \) for large \( n \) [2], any binary string representation of \( n \)-block floorplans must
use at least \( \log_2 11.56^n = 3.531n \) bits. Closing the gap between the known \((4n-4)\)-bit binary
representation and the \( 3.531n \) lower bound remains an open research problem [15].

Mosaic Floorplans:
It was shown in [6] that the set of \( n \)-block mosaic floorplans has a one-to-one correspondence to the set of Baxter permutations, and the number of \( n \)-block mosaic floorplans equals to the \( n \)th Baxter number \( B(n) \), which is defined as the following:

\[
B(n) = \left( \begin{array}{c} n+1 \\ 1 \end{array} \right)^{-1} \left( \begin{array}{c} n+1 \\ 2 \end{array} \right)^{-1} \sum_{r=0}^{n-1} \left( \begin{array}{c} n+1 \\ r \end{array} \right) \left( \begin{array}{c} n+1 \\ r+1 \end{array} \right) \left( \begin{array}{c} n+1 \\ r+2 \end{array} \right)
\]

In [14], it was shown that \( B(n) = \Theta(8^n/n^4) \). The first few Baxter numbers (staring from \( n = 1 \)) are \{1, 2, 6, 22, 92, 422, 2074, \ldots \}.

There is a long list of papers on representation problem of mosaic floorplans. [11] proposed a sequence pair (SP) representation. Two sets of permutations are used to represent the position relations between blocks. The length of the representation is \( 2n \log_2 n \) bits.

[9] proposed a corner block list (CB) representation for mosaic floorplans. The representation consists of a list \( S \) of blocks, a binary string \( L \) of \((n - 1)\) bits, and a binary string \( T \) of \( 2n - 3 \) bits. The total length of the representation is \((3n + n \log_2 n)\) bits.

[10] proposed a twin binary sequences (TBS) representation for mosaic floorplans. The representation consists of 4 binary strings \((\pi, \alpha, \beta, \beta')\), where \( \pi \) is a permutation of integers \( \{1, 2, \ldots, n\} \), and the other three strings are \( n \) or \((n - 1)\) bits long. The total length of the representation is \( 3n + n \log_2 n \).

A common feature of above representations is that each block in the mosaic floorplan is given an explicit name (such as an integer between 1 and \( n \)). They all use at least one list (or permutation) of these names in the representation. Because at least \( \log_2 n \) bits are needed to represent every integer in the range \([1, n]\), the length of these representations is inevitably at least \( n \log_2 n \) bits.

A different approach was introduced in [18]. They use a pair of twin pair binary trees \( t_1 \) and \( t_2 \) to represent mosaic floorplans. The blocks of the mosaic floorplan are not given explicit names. Rather, the shape of the two trees \( t_1 \) and \( t_2 \) are used to encode the position relations of blocks. In this representation, each tree consists of \( 2n \) nodes. Thus, each tree can be encoded by using \( 4n \) bits. So the total length of the representation is \( 8n \) bits. They also proposed an alternate representation using a pair of \( n \)-node trees. However, the nodes in the two trees are given names, and the length of the representation is at least \( 2n \log_2 n \).

In [13], a representation called quarter-state-sequence (QSS) was presented. It uses a \( Q \) sequence that represents the configuration of one of the corners of the mosaic floorplan. The length of the \( Q \) sequence representation is \( 4n \) bits. This is the best known representation for mosaic floorplans.

Because the number of \( n \)-block mosaic floorplans equals the \( n \)th Baxter number, at least \( \log_2 B(n) = \log_2 \Theta(8^n/n^4) = 3n - o(n) \) bits are needed to represent mosaic floorplans.

### 1.5 Our Main Result

**Theorem 1** The set of \( n \)-block mosaic floorplans can be represented by \((3n - 3)\) bits, which is optimal up to an additive lower order term.

Most binary representations of mosaic floorplans discussed in section [14] are fairly complex. In contrast, the representation introduced in this paper is very simple and easy to implement.

By using the simple one-to-one correspondence between mosaic floorplans and Baxter permutations described in [1], the methods presented in this paper also work on Baxter permutations.
Hence, our optimal representation of mosaic floorplans also leads to an optimal representation of Baxter permutations and all other objects in the Baxter combinatorial family.

2 Optimal Binary Representation of Mosaic Floorplans

In this section, we describe our optimal representation of mosaic floorplans.

2.1 Standard Form of Mosaic Floorplans

In the following, we introduce the notion of standard form of mosaic floorplans, which plays a central role in our representation.

Let $M$ be a mosaic floorplan. Let $h$ be a horizontal line segment in $M$. The upper segment set of $h$ and the lower segment set of $h$ are defined as the following:

$\text{ABOVE}(h) =$ the set of vertical line segments of $M$ that intersect $h$ and are above $h$.
$\text{BELOW}(h) =$ the set of vertical line segments of $M$ that intersect $h$ and are below $h$.

Similarly, for a vertical line segment $v$ in $M$, the left segment set of $v$ and the right segment set of $h$ are defined as the following:

$\text{LEFT}(v) =$ the set of horizontal segments of $M$ that intersect $v$ and are on the left of $v$.
$\text{RIGHT}(v) =$ the set of horizontal segments of $M$ that intersect $v$ and are on the right of $v$.

![Figure 3: Standard form of mosaic floorplans.](image)

**Definition 5** A mosaic floorplan $M$ is in standard form if the following hold:

1. For every horizontal segment $h$ in $M$, all vertical segments in $\text{ABOVE}(h)$ appear to the right of all vertical segments in $\text{BELOW}(h)$. (See Figure 3(a).)

2. For every vertical segment $v$ in $M$, all horizontal segments in $\text{RIGHT}(v)$ appear above all horizontal segments in $\text{LEFT}(v)$. (See Figure 3(b).)

The mosaic floorplan shown in Figure 3(c) is the standard form of mosaic floorplans shown in Figure 3(a) and Figure 3(b).
The standard form $M_{\text{standard}}$ of a mosaic floorplan $M$ can be obtained by sliding its vertical and horizontal line segments. Because of the equivalence definition of mosaic floorplans, $M_{\text{standard}}$ and $M$ are considered the same mosaic floorplans. For a given $M$, $M_{\text{standard}}$ can be obtained in linear time by using the horizontal constraint graphs and vertical constraint graphs described in [9]. From now on, all mosaic floorplans are assumed to be in standard form.

2.2 Staircases

**Definition 6** A staircase is an object that satisfies the following conditions:

1. The border contains a line segment on the $x$-axis and a line segment on the $y$-axis.

2. The remainder of the border is a non-increasing line segments consisting of vertical and horizontal line segments.

3. The interior is divided into smaller rectangular subsections by horizontal and vertical line segments.

4. No four subsections meet at the same point.

Figures 4: A staircase with $n = 6$ blocks and $m = 3$ steps that is obtained from the mosaic floorplan in Figure 1 (c) by deleting the blocks $b, c$ and $f$.

A step of a staircase $S$ is a horizontal line segment on the border of $S$, excluding the $x$-axis. Figure 4 shows a staircase with $n = 6$ blocks and $m = 3$ steps. Note that a mosaic floorplan is just a special case of a staircase with $m = 1$ step.

2.3 Deletable Rectangles

**Definition 7** A deletable rectangle of a staircase $S$ is a block that satisfies the following conditions:

1. Its top edge is completely contained in the border of $S$.

2. Its right edge is completely contained in the border of $S$.

In the staircase shown in Figure 4, the block $a$ is the only deletable rectangle. The concept of deletable rectangles is a key idea for the methods introduced in this paper. This concept was originally defined in [15] for their $(4n - 4)$-bit representation of floorplans. However, a modified definition of deletable rectangles is used in this paper to create a $(3n - 3)$-bit representation of mosaic floorplans.
Lemma 1  The removal of a deletable rectangle from a staircase results in another staircase unless the original staircase contains only one block.

Proof:  Let $S$ be a staircase with more than one block and let $r$ be a deletable rectangle in $S$. Define $S'$ to be the object that results when $r$ is removed from $S$. Because the removal of $r$ still leaves $S'$ with at least one block, the border of $S'$ still contains a line segment on the $x$-axis and a line segment on the $y$-axis, so condition (1) of a staircase holds for $S'$. Removing $r$ will not cause the remainder of the border to have an increasing line segment because the right edge of $r$ must be completely contained in the border, so condition (2) of a staircase also holds for $S'$. The removal of $r$ does not form new line segments, so the interior of $S'$ will still be divided into smaller rectangular subsections by vertical and horizontal line segments, and no four subsections in $S'$ will meet at the same point. Thus, conditions (3) and (4) of a staircase hold for $S'$. Therefore, $S'$ is a staircase. □

We can now outline the basic ideas of our representation. Given a mosaic floorplan $M$, we remove deletable rectangles of $M$ one by one. By Lemma 1 this results in a sequence of staircases, until only one block remains. We record necessary location information of these deletable rectangles (which will be the binary representation of $M$) so that we can reconstruct the original floorplan $M$. However, if there are multiple deletable rectangles for these staircases, we will have to use more bits than we can afford. Fortunately, the following key lemma shows that this does not happen.

Lemma 2 Let $M$ be a $n$-block mosaic floorplan in standard form. Let $S_n = M$, and let $S_{i-1}$ ($2 \leq i \leq n$) be the staircase obtained by removing a deletable rectangle $r_i$ from $S_i$.

1. There is a single, unique deletable rectangle in $S_i$ for $1 \leq i \leq n$.

2. $r_{i-1}$ is adjacent to $r_i$ for $2 \leq i \leq n$.

Proof:  The proof is by reverse induction.

Clearly, $S_n = M$ has only one deletable rectangle located at the top right corner of $M$.

Assume that $S_{i+1}$ ($i \leq n - 1$) has exactly one deletable rectangle $r_{i+1}$. Let $h$ be the horizontal line segment in $S_{i+1}$ that contains the bottom edge of $r_{i+1}$, and let $v$ be the vertical line segment in $S_{i+1}$ that contains the left edge of $r_{i+1}$ (see Figure 5). Let $a$ be the uppermost block in $S_{i+1}$ whose right edge aligns with $v$, and let $b$ be the rightmost block in $S_{i+1}$ whose top edge aligns with $h$. After $r_{i+1}$ is removed from $S_{i+1}$, $a$ and $b$ are the only candidates for deletable rectangles of the resulting staircase $S_i$. There are two cases:

![Figure 5: Proof of Lemma 2](image-url)
1. The line segments \( h \) and \( v \) form a \( \perp \)-junction (see Figure 5 (a).) Then, the bottom edge of \( a \) must be below \( h \) because \( M \) is a standard mosaic floorplan, and \( a \) is not a deletable rectangle in \( S_i \). Thus, the block \( b \) is the only deletable rectangle in \( S_i \).

2. The line segments \( h \) and \( v \) form a \( \perp \)-junction (see Figure 5 (b).) Then, the left edge of \( b \) must be to the left of \( v \) because \( M \) is a standard mosaic floorplan, and \( b \) is not a deletable rectangle in \( S_i \). Thus, the block \( a \) is the only deletable rectangle in \( S_i \).

In both cases, only one deletable rectangle \( r_i \) (which is either \( a \) or \( b \)) is revealed when the deletable rectangle \( r_{i+1} \) is removed. Because there is only one deletable rectangle in \( S_n = M \), all subsequent staircases contain exactly one deletable rectangle. Thus, (1) is true. Also, \( r_{i+1} \) is adjacent to \( r_i \) in both cases, so (2) is true. □

Let \( S \) be a staircase and \( r \) be a deletable rectangle of \( S \) whose top side is on the \( k \)-th step of \( S \). There are four types of deletable rectangles.

![Figure 6: The four types of deletable rectangles.](image)

1. Type (0,0):
   (a) The top side of \( r \) is the entire \( k \)-th step.
   (b) The right side of \( r \) intersects the \((k-1)\)-th step.
   (c) The deletion of \( r \) decreases the number of steps by one.

2. Type (0,1):
   (a) The top side of \( r \) is only a part of the \( k \)-th step.
   (b) The right side of \( r \) intersects the \((k-1)\)-th step.
   (c) The deletion of \( r \) does not change the number of steps.

3. Type (1,0):
   (a) The top side of \( r \) is the entire \( k \)-th step.
   (b) The right side of \( r \) is only a part of the right side of the \( k \)-th step (namely the right-bottom corner of \( r \) is a \( \perp \) shape junction).
   (c) The deletion of \( r \) does not change the number of steps.

4. Type (1,1):

(a) The top side of \( r \) is only a part of the \( k \)-th step.
(b) The right side of \( r \) is only a part of the right side of the \( k \)-th step (namely the right-bottom corner of \( r \) is a \( \unrhd \) shape junction).
(c) The deletion of \( r \) increases the number of steps by one.

### 2.4 Optimal Binary Representation

Our binary representation of mosaic floorplans depends on the fact that a mosaic floorplan \( M \) is a special case of a staircase and the fact that the removal of a deletable rectangle from a staircase results in another staircase. The binary string used to represent \( M \) records the unique sequence of deletable rectangles that are removed in this process. The information stored by this binary string enable us to reconstruct the original mosaic floorplan \( M \).

A 3-bit binary string is used to record the information for each deletable rectangle \( r_i \). The string has two parts: The type and the location of \( r_i \). To record the type of \( r_i \), the bits corresponding to its type is stored directly. To store the location, we note that, by Lemma 2, two consecutive deletable rectangles \( r_i \) and \( r_{i-1} \) are adjacent to each other. Thus, they must share either a horizontal edge or a vertical edge. A single bit can be used to record the location of \( r_i \) with respect to \( r_{i-1} \): a 1 if they share a horizontal edge, and a 0 if they share a vertical edge.

**Encoding Procedure:**

Let \( M \) be the \( n \)-block mosaic floorplan to be encoded. Starting from \( S_n = M \), remove the unique deletable rectangles \( r_i \), where \( 2 \leq i \leq n \), one by one. For each deletable rectangle \( r_i \), two bits are used to record the type of \( r_i \), and one bit is used to record the type of the common boundary shared by \( r_i \) and \( r_{i-1} \).

![Figure 7: An example of the presentation.](image-url)
Decoding Procedure:

The decoding procedure simply reverses the process of removing deletable rectangles. The process starts with the staircase $S_1$, which is a single rectangle. Each staircase $S_{i+1}$ can be reconstructed from the staircase $S_i$ by using the three-bit code for the deletable rectangle $r_{i+1}$. The three-bit code records the type of $r_{i+1}$ and the type of edge shared by $r_i$ and $r_{i+1}$, so $r_{i+1}$ can be uniquely added to $S_i$. Thus, the decoding procedure can reconstruct original mosaic floorplan $S_n = M$.

Figure 7 show an example of the reconstruction of a mosaic floorplan from its representation:

```
000 011 101 000 110 111
```

The lower left block of the mosaic floorplan $M$ (which is the only block of $S_1$) does not need any information to be recorded. Each of the other blocks of $M$ needs three bits. Thus the total length of the binary representation of $M$ is $(3n - 3)$ bits. This completes the proof of Theorem 1.

3 Conclusion

In this paper, we introduced a binary representation of $n$-block Mosaic floorplans. The representation uses $(3n - 3)$ bits. Since any representation of $n$-block mosaic floorplans requires at least $(3n - o(n))$ bits [14], our representation is optimal (up to an additive lower term). Our representation is very simple and easy to implement.

Mosaic floorplans are known to have a simple one-to-one correspondence with Baxter permutations. So the method used to represent mosaic floorplans in this paper also lead to an optimal $(3n - 3)$ bits representation of Baxter permutation of length $n$, and all objects in the Baxter combinatorial family.
