A Mean Field Game Approach to Equilibrium Pricing with Market Clearing Condition

Masaaki Fujii, Akihiko Takahashi

First version: 6 March, 2020
This version: 25 September, 2021

Abstract

In this work, we study an equilibrium-based continuous asset pricing problem which seeks to form a price process endogenously by requiring it to balance the flow of sale-and-purchase orders in the exchange market, where a large number of agents \(1 \leq i \leq N\) are interacting through the market price. Adopting a mean field game (MFG) approach, we find a special form of forward-backward stochastic differential equations of McKean-Vlasov type with common noise whose solution provides an approximate of the market price. We show the convergence of the net order flow to zero in the large \(N\)-limit and get the order of convergence in \(N\) under some conditions. An extension of the model to a setup with multiple populations, where the agents within each population share the same cost and coefficient functions but they can be different population by population, is also discussed.

Keywords: FBSDE of McKean-Vlasov type, common noise, general equilibrium

1 Introduction

One of the most important problems in financial economics is to understand how the asset price processes are formed through the interaction among a large number of rational competitive agents. In this paper, using a stylized model of security exchange, we try to explicitly form an approximate market price process which balances the flow of sale-and-purchase orders from a large number of rational financial firms. If we directly force the price process to balance the net order flow, the strategies of the agents become strongly coupled and the problem is hardly solvable. In fact, it is even unclear how to make the cost functions of the agents well-defined, since the market price results in a very complicated recursive functional of strategies of all the agents that makes it difficult to guarantee the convexity of the cost functions. In order to circumvent this problem, we make use of the recent developments of mean field games.

Since its inception brought by the pioneering works of Lasry & Lions [32, 33, 34] and Huang, Malhame & Caines [29], mean field game has rapidly developed into one of the most actively studied topics in the field of probability theory, applied mathematics, engineering, finance and economics. The greatest strength of the mean field game approach is to render notoriously...
difficult problems of stochastic differential games among many agents tractable by transforming it to a simpler form of stochastic control problems. There exist two approaches to the mean field games, one is analytic approach using partial differential equations (PDEs), and the others is probabilistic approach based on forward-backward stochastic differential equations (FBSDEs). For details of analytic approach and its applications, the interested readers may consult the works of Bensoussan, Frehse & Yam [9], Gomes, Nurbekyan & Pimentel [25], Achdou et.al. [1], Gomes, Pimentel & Voskanian [26] and also Kolokoltsov & Malafeyev [30]. On the other hand, the probabilistic approach was developed by the series of works of Carmona & Delarue [10, 11, 12] and the recent two volumes of monograph [13, 14] provide its full mathematical details and many references for a wide array of applications of mean field games.

There are many macroeconomic applications of mean field games, in particular, those focusing on general equilibrium models on growth, inequality and unemployment, etc. See [3, 7, 24, 31] for examples. On the other hand, in the current paper, we are interested in equilibrium price formation in the financial market i.e. the pricing of securities endogenously using a model of rational financial firms (agents) under the market clearing condition. Interestingly, from the perspective of equilibrium price formation, the number of applications of mean field games is rather limited. In most of the existing literature, authors have given a response function of the price process exogenously and searched an approximate Nash equilibrium among the agents. See, for example, applications to optimal trading as well as liquidation of portfolio, exploitation of exhaustible resources and related issues among many agents [17, 18, 19, 35], or applications to electricity pricing with smart grids [14, 15]. Another approach is to assume demand or supply function exogenously without directly solving the individual agent optimization problem. For example, in the work [28], the authors treat explicitly the balance of demand and supply in the oil market, but the demand is exogenously given as a function of the oil price. Although these approaches make the setup nicely fit to the concept of Nash equilibrium, which is the standard solution concept in the mean field games, the market clearing equilibrium cannot be investigated anymore. In fact, the endogenous relation between the price processes and the properties of individual agent is left unknown. One notable exception is the work of Gomes & Saude [27], in which the authors explicitly force demand and supply to balance and endogenously construct the market clearing electricity price. They use the analytic approach and the resultant equilibrium price process becomes deterministic due to the absence of common noise.

In the current paper, we extend the work [27] by adopting the probabilistic approach. In order to understand the price processes, in particular those of financial assets, including systemic signals which impact all the agents is crucially important. We find an interesting form of FBSDEs of McKean-Vlasov type with common noise as a limit problem. Although it involves dependence in conditional law, it only appears as a conditional expectation. This allows us to adopt the well-known Peng-Wu’s continuation method [37] to prove the existence of a unique strong solution. The resultant candidate of the market price process is derived completely endogenously by the optimal trading strategies of the agents facing systemic information (including securities’ coupon stream) as well as idiosyncratic noise. Another benefit of probabilistic approach is that it allows us to quantify the relation between the actual game with finite number of agents and its large population limit. In a similar manner to the standard mean field games in proving ε-Nash equilibrium, we show that the solution of the mean-field limit problem actually provides asymptotic market clearing in the large-N limit. Under additional integrability conditions, Glivenko-Cantelli convergence theorem in the Wasserstein distance even provides a specific order of convergence in terms of the number of agents $N$. It is also possible to extend the model to the situation with multiple populations where the agents share the same cost and coefficient
functions within each population but they can be different population by population. This will provide an important tool to study the price formation in the presence of different type of agents such as Buy-side and Sell-side institutions, for example.

The organization of the paper is as follows: After explaining the notations in Section 2, we give an intuitive derivation of the limit problem from the game of finite number of agents in Section 3 which motivates the readers to study the special form of FBSDEs of MKV-type. The solvability of the FBSDE is studied in Section 4. Using the derived regularity of the solution, we prove the asymptotic market clearing in Section 5. In Section 6, we discuss the extension of the model to the setup with multiple populations. Finally, in Section 7, we give concluding remarks. We discuss further extensions of the model and future directions of research.

2 Notations

We introduce \((N+1)\) complete probability spaces:

\[
\left( \Omega^0, \mathcal{F}^0, \mathbb{P}^0 \right) \quad \text{and} \quad \left( \Omega^i, \mathcal{F}^i, \mathbb{P}^i \right)_{i=1}^{N},
\]

endowed with filtrations \( \mathcal{F}^i := (\mathcal{F}^i_t)_{t \geq 0}, \) \( i \in \{0, \ldots, N\} \). Here, \( \mathcal{F}^0 \) is the completion of the filtration generated by \( d^0 \)-dimensional Brownian motion \( W^0 \) (hence right-continuous) and, for each \( i \in \{1, \ldots, N\} \), \( \mathcal{F}^i \) is the complete and right-continuous augmentation of the filtration generated by \( d \)-dimensional Brownian motions \( W^i \) as well as a \( W^i \)-independent \( n \)-dimensional square-integrable random variables \( (\xi^i) \). \( (\xi^i)_{i=1}^{N} \) are supposed to have the same law. We also introduce the product probability spaces

\[
\Omega^i = \Omega^0 \times \Omega^i, \quad \mathcal{F}^i = (\mathcal{F}^i_t)_{t \geq 0}, \quad \mathbb{P}^i, \quad i \in \{1, \ldots, N\}
\]

where \( (\mathcal{F}^i, \mathbb{P}^i) \) is the completion of \( (\mathcal{F}^0 \otimes \mathcal{F}^i, \mathbb{P}^0 \otimes \mathbb{P}^i) \) and \( \mathcal{F}^i \) is the complete and right-continuous augmentation of \( (\mathcal{F}^0_t \otimes \mathcal{F}^i_t)_{t \geq 0} \). In the same way, we define the complete probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \) endowed with \( \mathbb{F} = (\mathcal{F}_t)_{t \geq 0} \) satisfying the usual conditions as a product of \( (\Omega^i, \mathcal{F}^i, \mathbb{P}^i; \mathbb{F}^i)_{i=0}^{N} \).

Throughout the work, the symbol \( L \) denotes a given positive constant, the symbol \( C \) a general positive constant which may change line by line. When we want to emphasize that \( C \) depends only on some specific variables, say \( a \) and \( b \), we use the symbol \( C(a,b) \).

For a given constant \( T > 0 \) and any measurable space \( (\Omega, \mathcal{G}) \) with the filtration \( \mathcal{G} := (\mathcal{G}_t)_{t \geq 0} \), we use the following notations for frequently encountered spaces:

- \( L^2(\mathcal{G}; \mathbb{R}^d) \) denotes the set of \( \mathbb{R}^d \)-valued \( \mathcal{G} \)-measurable square integrable random variables.
- \( S^2(\mathcal{G}; \mathbb{R}^d) \) is the set of \( \mathbb{R}^d \)-valued \( \mathcal{G} \)-adapted continuous processes \( X \) satisfying
  \[
  ||X||_{S^2} := \mathbb{E}\left[ \sup_{t \in [0,T]} |X_t|^2 \right]^\frac{1}{2} < \infty.
  \]

- \( H^2(\mathcal{G}; \mathbb{R}^d) \) is the set of \( \mathbb{R}^d \)-valued \( \mathcal{G} \)-progressively measurable processes \( Z \) satisfying
  \[
  ||Z||_{H^2} := \mathbb{E}\left[ \left( \int_0^T |Z_t|^2 \, dt \right)^\frac{1}{2} \right] < \infty.
  \]

- \( \mathcal{L}(X) \) denotes the law of a random variable \( X \).
\( \mathcal{P}(\mathbb{R}^d) \) is the set of probability measures on \((\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d))\).

\( \mathcal{P}_p(\mathbb{R}^d) \) with \( p \geq 1 \) is the subset of \( \mathcal{P}(\mathbb{R}^d) \) with finite \( p \)-th moment i.e., the set of \( \mu \in \mathcal{P}(\mathbb{R}^d) \) satisfying

\[
M_p(\mu) := \left( \int_{\mathbb{R}^d} |x|^p \mu(dx) \right)^{\frac{1}{p}} < \infty.
\]

We always assign \( \mathcal{P}_p(\mathbb{R}^d) \) with \( p \geq 1 \) the \( p \)-Wasserstein distance \( W_p \), which makes \( \mathcal{P}_p(\mathbb{R}^d) \) a complete separable metric space. It is defined by, for any \( \mu, \nu \in \mathcal{P}_p(\mathbb{R}^d) \),

\[
W_p(\mu, \nu) := \inf_{\pi \in \Pi_p(\mu, \nu)} \left[ \left( \int_{\mathbb{R}^d \times \mathbb{R}^d} |x - y|^p \pi(dx, dy) \right)^{\frac{1}{p}} \right]
\]  
(2.1)

where \( \Pi_p(\mu, \nu) \) denotes the set of probability measures in \( \mathcal{P}_p(\mathbb{R}^d \times \mathbb{R}^d) \) with marginals \( \mu \) and \( \nu \).

For more details, see [13, Chapter 5]. We frequently omit the arguments such as \((G, G, \mathbb{R}^d)\) in the above definitions when there is no confusion from the context.

### 3 Intuitive Derivation of the Mean Field Problem

In this section, in order to introduce the special form of forward-backward stochastic differential equations of McKean-Vlasov type to be studied in this paper, we give a heuristic derivation of the mean-field limit problem from the corresponding equilibrium problem with finite number of agents.

#### 3.1 Description of the problem

As a motivating example, consider the equilibrium-based pricing problem of \( n \) types of securities labeled by \( k \), \( 1 \leq k \leq n \), which are continuously traded via the securities exchange in the presence of a large number of homogeneous financial firms (agents) indexed by \( i \), \( 1 \leq i \leq N \). Every agent is supposed to have many small individual clients who can trade the securities only with the agent via the over-the-counter (OTC) market and have no direct access to the exchange.\(^1\) We denote the market price process of the \( n \) securities by an \( \mathbb{R}^n \)-valued process \((\pi_t)_{t \in [0,T]}\), the detailed mathematical properties of which are to be discussed later. Here, \((\pi_t)^k\) denotes the market price of the \( k \)th security at time \( t \). In our model, the state process \((X_t^i)_{t \in [0,T]}\) of each agent \( i \), \( 1 \leq i \leq N \), is given by the time evolution of his/her position size in the \( n \) securities. For example, let us suppose that the \( k \)th security is an equity of a certain company. Then \((X_t^i)^k\) denotes the number of shares of the equity possessed by the \( i \)th agent at time \( t \). If it is negative, it means that the agent is taking the short position. Each agent \( i \), \( 1 \leq i \leq N \), controls the trading speed of the securities \((\alpha_t^i)_{t \in [0,T]}\) via the exchange within some space of admissible strategies \( \mathcal{A}^i \). More precisely, \((\alpha_t^i)^k dt\), \( 1 \leq k \leq n \), denotes the number of shares of the \( k \)th security bought (or sold if negative) within the time interval \([t, t + dt]\) by the \( i \)th agent. In addition to the trading via the exchange, the position size of each agent is affected by his/her market making via the OTC market with individual clients. Although, in the real market, each financial firm dynamically controls bid-offer spreads in order to earn trading fees and to affect

\(^1\)In fact, only credit-worthy registered financial firms are allowed to directly participate in the securities exchange. The individual investors and non-financial firms can trade the securities with these registered firms playing the role of financial intermediaries. This is called the over-the-counter (OTC) market.
the order flows from his/her clients in a favorable manner to his/her profit, we treat, in this work, the order flows via the OTC market exogenous and concentrate on the optimal trading problem via the securities exchange for simplicity. We denote by \((c_t^i)_{t \geq 0} \in \mathbb{H}^2(F^i_t; \mathbb{R}^n)\) with \(c_t^0 \in \mathcal{L}^2(F^i_T; \mathbb{R}^n)\) the cash flows from the securities or the market news commonly available to all the agents, while by \((c_t^i)_{t \geq 0} \in \mathbb{H}^2(F^i_t; \mathbb{R}^n)\) with \(c_T^i \in \mathcal{L}^2(F^i_T; \mathbb{R}^n)\) some independent factors and news affecting only on the agent \(i\). Moreover, we assume that \((c_t^i)_{t \geq 0}\) have the common law for all \(1 \leq i \leq N\).

Let us introduce the measurable functions, \(l : [0, T] \times (\mathbb{R}^n)^3 \to \mathbb{R}^n\), \(\sigma_0 : [0, T] \times (\mathbb{R}^n)^3 \to \mathbb{R}^{n \times d_0}\) and \(\sigma : [0, T] \times (\mathbb{R}^n)^3 \to \mathbb{R}^{n \times d}\). Using them, we now express the state dynamics of each agent \(i, 1 \leq i \leq N\), by

\[
dX_t^i = (\alpha_t^i + l(t, \varpi_t, c^0_t, c^i_t))dt + \sigma_0(t, \varpi_t, c^0_t, c^i_t)dW_t^0 + \sigma(t, \varpi_t, c^0_t, c^i_t)dW_t^i
\]

with \(X_0^i = \xi^i \in \mathcal{L}^2(F^i_0; \mathbb{R}^n)\). \(\xi^i\) denotes the initial position size of the \(i\)th agent and is assumed to be independently and identically distributed (i.i.d.) among \(1 \leq i \leq N\). In addition to \(\alpha_t^idt\) representing the change due to the direct trading via the exchange, there also exist contributions from the order flows via the OTC market: \(l(t, \varpi_t, c^0_t, c^i_t)dt\) and \((\sigma_0(t, \varpi_t, c^0_t, c^i_t)dW_t^0\), \(\sigma(t, \varpi_t, c^0_t, c^i_t)dW_t^i\) denote their finite and infinite variation parts, respectively. We naturally expect that these order flows are dependent on the price of the securities, common as well as idiosyncratic informations. Suppose, for example, \(l^k(t, \varpi_t, c^0_t, c^i_t) < 0\). This means that the clients of the \(i\)th agent are buying the \(k\)th security from the agent via the OTC market with the net speed \(|l^k(t, \varpi_t, c^0_t, c^i_t)|\) at time \(t\). The two infinite variation terms represent the noise in the order flows.

Under such an environment, each agent tries to minimize his/her cost by controlling the trading speed. We suppose that the problem for each agent \(1 \leq i \leq N\) is given by

\[
\inf_{\alpha^i \in \mathcal{A}^i} J^i(\alpha^i) \tag{3.1}
\]

with some cost functional

\[
J^i(\alpha^i) := \mathbb{E}\left[\int_0^T f(t, X_t^i, \alpha_t^i, \varpi_t, c_t^0, c_t^i)dt + g(X_T^i, \varpi_T, c_T^0, c_T^i)\right].
\]

The space of admissible strategies \(\mathcal{A}^i\) of the agent \(i\) is assumed to be \(\mathbb{H}^2(\mathbb{R}^n : s \leq t) \vee \mathcal{F}^i_{t \geq 0} ; \mathbb{R}^n\) i.e. the set of processes \((\alpha_t^i)_{t \geq 0}\) satisfying

\[
\mathbb{E}\int_0^T |\alpha_t^i|^2dt < \infty
\]

adapted to the filtration generated by the common and his/her idiosyncratic shocks as well as the market price process of the securities.

**Remark 3.1 (possible choices of the duration \(T\)).** Since most of the financial firms set up the policies on profit, risk and storage level of securities for each fiscal period, a natural choice of the duration \(T\) of the model is (quarter of) a year. In fact, financial firms typically reduce the size of securities’ position significantly at the end of each fiscal year, for regulatory as well as accounting

\[\text{The dimensions of } c^0 \text{ and } c^i \text{ are chosen to be } n \text{ only for the notational simplicity. One can assign any fixed dimensions for them so that they can represent any factors that affect the agents’ cost functions.}\]
reasons, and announce new budgetary goals to the employees for the next year. If one is interested in the price dynamics in shorter scale among high-frequency traders, an appropriate choice for the duration $T$ can be much shorter. For analyzing the long-term behavior of price dynamics, infinite time horizon may become important [8]. We leave its application to equilibrium price formation for future research.

We introduce the following cost functions; $f : [0, T] \times (\mathbb{R}^n)^6 \to \mathbb{R}$, $g : (\mathbb{R}^n)^4 \to \mathbb{R}$, $\overline{f} : [0, T] \times (\mathbb{R}^n)^4 \to \mathbb{R}$ and $\overline{g} : (\mathbb{R}^n)^3 \to \mathbb{R}$, which are measurable functions such that

$$f(t, x, \alpha, \omega, c^0, c) := \langle \omega, \alpha \rangle + \frac{1}{2} \langle \alpha, \Lambda \alpha \rangle + \overline{f}(t, x, \omega, c^0, c),$$

$$g(x, \omega, c^0, c) := -b \langle \omega, x \rangle + \overline{g}(x, c^0, c).$$

In the first part of the paper, we assume that these functions are common across all the agents. In the above expression, $f$ and $g$ denote the running and the terminal costs, respectively. Let us explain the economic meaning of each term. By buying (or selling if negative) with speed $\alpha_t$, each agent pays (or receives if negative) $\langle \alpha_t, \omega_t \rangle dt$ amount of cash in the time interval $[t, t+dt]$. In addition to this direct cost, we suppose that each agent has to pay the service fees to the securities exchange $\langle \alpha_t, \Lambda \alpha_t \rangle dt$ where $\Lambda$ is an $n \times n$ positive definite matrix. These costs are represented by the first two terms of the function $f$. In addition, each agent is subject to the costs incurred by the financial risk as well as the appropriate inventory management of his/her position. The cost function $\overline{f}$ is supposed to represent these effects, which are dependent on the position size, cash flows, prices of the securities as well as any relevant news available to each agent. In particular, we can make the agents more risk averse by assigning stronger penalty on their nonzero position $|X|$ of the securities. The first term of $g$ denotes the mark-to-market value at the closing time with some discount factor $b < 1$. The cost function $\overline{g}$ puts some penalty on the position size at the terminal time $T$.

If the price process $(\omega_t)_{t \in [0, T]}$ is given exogenously (for example, by the Black-Scholes model $dS_t = S_t(\mu dt + \sigma dW_t), t \geq 0$), the problem (3.1) is just the standard optimal portfolio problem with a stochastic inventory process. In this case, the problem can be considered independently for each agent. Using the position size as the state process with a linear control term is quite popular in the literature. For example, one can find similar setups in optimal liquidation problems [5, 6, 38] and also in their mean-field extensions [17, 18, 19, 35]. By interpreting the variable $X$ as the amount of goods or energy produced and $\alpha$ as the production speed, similar setups for the state process can also be found in papers studying economic problems. See, for example, [28, 4] and references therein. An important feature in the existing literature is that the optimal control or a Nash equilibrium among the agents is searched in the market where the price process or its response function to the agents’ actions is exogenously given.

In contrast, in the current paper, we want to determine the price process itself endogenously by the fundamental condition of the market. As its name suggests, the total number of shares of the securities being purchased by agents via the securities exchange at a given time must be equal to the number of those being sold by the others via the exchange at the same time. This balance between the sales and purchases orders must hold at any point in time. This is called

---

3We shall see that the condition $b < 1$ is necessary to obtain well-defined terminal condition for the limit problem.
the market clearing condition and is expressed by

$$\sum_{i=1}^{N} \alpha_i = 0 \ , \ \ dt \otimes dP - \text{a.e.} \quad (3.2)$$

where $\alpha_i$ is the optimal control of the $i$th agent. Our problem is to find an appropriate price process $(\pi_t)_{t \geq 0}$ so that it achieves the market clearing condition (3.2) among the rational agents. This is the problem of equilibrium price formation, which is one of the central themes in financial economics.

### 3.2 Intuitive derivation of the mean-field limit

Intuitively, by a simple economic argument, it is not hard to imagine that the market price automatically adjusts to the higher values if the excess demand is positive and does so conversely in the opposite case. However, understanding the problem in rigorous mathematical sense is not at all easy even though we have already put simplistic conditions in which the cost functions as well as the coefficient functions are the same across the agents. Due to the clearing condition (3.2), we cannot adopt the open-loop equilibrium approach. This means, in particular, if we assume the presence of some feedback effects, then the price process $(\pi_t)_{t \geq 0}$ becomes a complicated functional of the agents’ trading strategies and hence the problem for each agent is highly recursive with respect to $(\alpha^i_t)_{t \geq 0, 1 \leq i \leq N}$. It is even unclear how to guarantee the cost function well-defined by making it convex with respect to the controls.

In order to obtain some insight, let us consider a much simpler situation. It is natural to suppose that the impact to the market price process $(\pi_t)_{t \in [0, T]}$ from the trading of each agent is negligibly small when $N$ is sufficiently large. If an agent considers that his/her market share is negligibly small, he/she behaves as a price taker, i.e. considers that the market price process is not affected by his/her actions. Let us suppose that this is the case for every agent. Moreover, $(\pi_t)_{t \in [0, T]}$ is likely to be given by $F^0$-progressively measurable process since the effects from the idiosyncratic parts from many agents are expected to be canceled out. If this is the case, the problem for each agent $i$ reduces to the standard optimal portfolio problem with a stochastic inventory process of the securities in a given random environment $(\pi_t, c^0_t, c^1_t)_{t \in [0, T]}$. Note that if $(\pi_t)_{t \in [0, T]}$ is $F^0$-adapted, then the space of admissible strategies $\mathcal{A}^i$ of the agent $i$, $1 \leq i \leq N$, becomes $H^2(F^0; \mathbb{R}^n)$. Let us first investigate this simple problem in details. We introduce the following conditions.

**Assumption 3.1.**

(i) $\Lambda$ is a positive definite $n \times n$ symmetric matrix with $\underline{A}I_{n \times n} \leq \Lambda \leq \overline{A}I_{n \times n}$ in the sense of 2nd-order form where $\underline{A}$ and $\overline{A}$ are some constants satisfying $0 < \underline{A} \leq \overline{A}$.

(ii) For any $(t, x, \pi, c^0, c)$,

$$|\overline{f}(t, x, \pi, c^0, c)| + |\overline{g}(x, c^0, c)| \leq L(1 + |x|^2 + |\pi|^2 + |c^0|^2 + |c|^2) \ .$$

(iii) $\overline{f}$ and $\overline{g}$ are continuously differentiable in $x$ and satisfy, for any $(t, x, x', \pi, c^0, c)$,

$$\left| \partial_x \overline{f}(t, x', \pi, c^0, c) - \partial_x \overline{f}(t, x, \pi, c^0, c) \right| + \left| \partial_x \overline{g}(x', c^0, c) - \partial_x \overline{g}(x, c^0, c) \right| \leq L|x' - x| \ .$$

---

4In the standard economic theories, the market clearing is used to define the competitive equilibrium not only for securities but also for any goods with appropriate modifications. See, for example, [34, Chapter 10].
and $|\partial_x \overline{f}(t, x, \varpi, c^0, c)| + |\partial_x \overline{g}(x, c^0, c)| \leq L(1 + |x| + |\varpi| + |c^0| + |c|)$.

(iv) The functions $\overline{f}$ and $\overline{g}$ are convex in $x$ in the sense that for any $(t, x, x', \varpi, c^0, c)$,

$$
\overline{f}(t, x', \varpi, c^0, c) - \overline{f}(t, x, \varpi, c^0, c) - (x' - x, \partial_x \overline{f}(t, x, \varpi, c^0, c)) \geq \frac{\gamma_f}{2} |x' - x|^2,
$$

$$
\overline{g}(x', c^0, c) - \overline{g}(x, c^0, c) - (x' - x, \partial_x \overline{g}(x, c^0, c)) \geq \frac{\gamma_g}{2} |x' - x|^2,
$$

with some constants $\gamma_f, \gamma_g \geq 0$.

(v) $l, \sigma_0$ and $\sigma$ satisfy the linear growth condition:

$$
|(l, \sigma_0, \sigma)(t, \varpi, c^0, c)| \leq L(1 + |\varpi| + |c^0| + |c|)
$$

for any $(t, \varpi, c^0, c)$.

(vi) $b \in [0, 1]$ is a given constant.

**Remark 3.2.** If $c^0$ denotes a coupon stream of the securities, one may use for example,

$$
\overline{f}(t, x, \varpi, c^0, c) = -\langle c^0, x \rangle + \overline{f}(t, x, \varpi, c)
$$

as a running cost with an appropriate measurable function $\overline{f}$. As for securities with a given maturity $T$ with exogenously specified payoff $c^0$, such as bonds and futures, it is natural to consider

$$
g(x, c^0) = \overline{g}(x, c^0) = -\langle c^0, x \rangle
$$

as the terminal cost. Since the securities cease to exist at time $T$ after paying $c^0$, there is no reason to put the penalty on the terminal position size anymore.

For this problem, the (reduced) Hamiltonian is given by

$$
H(t, x, y, \alpha, \varpi, c^0, c) = \langle y, \alpha + l(t, \varpi, c^0, c) \rangle + f(t, x, \alpha, \varpi, c^0, c).
$$

Since $\partial_\alpha H(t, x, y, \alpha, \varpi, c^0, c) = y + \varpi + \Lambda \alpha$, the minimizer of the Hamiltonian is

$$
\hat{\alpha}(y, \varpi) := -\overline{\Lambda}(y + \varpi)
$$

(3.3)

where $\overline{\Lambda} := \Lambda^{-1}$. The adjoint FBSDE associated with the stochastic maximal principle for each agent $1 \leq i \leq N$ is thus given by,

$$
dX_t^i = \left(\hat{\alpha}(Y_t^i, \varpi_t) + l(t, \varpi_t, c_t^0, c_t^0)\right)dt + \sigma_0(t, \varpi_t, c_t^0, c_t^0)dW_t^0 + \sigma(t, \varpi_t, c_t^0, c_t^0)dW_t^i,
$$

$$
dY_t^i = -\partial_x \overline{f}(t, X_t^i, \varpi_t, c_t^0, c_t^0)dt + \sigma_t(t, \varpi_t, c_t^0, c_t^0)dW_t^0 + \sigma_t(t, \varpi_t, c_t^0, c_t^0)dW_t^i,
$$

(3.4)

with $X_0^i = \xi^i$ and $Y_0^i = \partial_x g(X_t^i, \varpi_T, c_T^0, c_T^0)$.

**Theorem 3.1.** Under Assumption 

and a given $(\varpi_t)_{t \in [0, T]} \in H^2(\overline{F}^0; \mathbb{R}^n)$ with $\varpi_T \in L^2(\overline{F}_T; \mathbb{R}^n)$, the problem 

for each agent is uniquely characterized by the FBSDE 

which is strongly solvable with a unique solution $(X^i, Y^i, Z^{i, 0}, Z^i) \in S^2(\overline{F}^i; \mathbb{R}^n) \times S^2(\overline{F}^i; \mathbb{R}^n) \times H^2(\overline{F}^i; \mathbb{R}^{n \times d}) \times H^2(\overline{F}^i; \mathbb{R}^{n \times d})$.

**Proof.** Since the cost functions are jointly convex with $(x, \alpha)$ and strictly convex in $\alpha$, the
problem is the special situation investigated in [13, Section 1.4.4]. Note that, in our case, the diffusion terms \( \sigma_0, \sigma \) are independent of \((X^i, \alpha^i)\). Hence the proof is the direct result of [13, Theorem 1.60].

Using the above solution, the optimal strategy of each agent is given by

\[
\hat{\alpha}^i_t = -\mathbb{N}(Y^i_t + \omega_t), \quad t \in [0, T].
\]

Let us check the market clearing condition. In the current situation, \((\omega_t)_{t \geq 0}^N\) is equivalent to

\[
\omega_t = -\frac{1}{N} \sum_{i=1}^N Y^i_t
\]

which is of course inconsistent with the our simplifying assumption that requires \((\omega_t)_{t \geq 0}^N\) to be an \(\mathbb{F}^0\)-adapted process. However, in the current setup, for any \( t \in [0, T] \), \((Y^i_t)_{i=1}^N\) are exchangeable random variables due to the construction of the probability space, common coefficient functions, and the fact that \( (\xi^i)_{i=1}^N \) as well as \( (c^i_t, t \in [0, T])_{i=1}^N\) are assumed to be i.i.d. Thus De Finetti’s theory of exchangeable sequence of random variables tells

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N Y^i_t = \mathbb{E}[Y^1_t \big| \mathcal{F}^0_t] \quad \text{a.s.}
\]

See for example [13, Theorem 2.1]. It also seems natural to expect that the tail \(\sigma\)-field is reduced to \(\mathcal{F}^0_t\). Therefore we can expect that, in the large-\(N\) limit, the market price of the securities may be given by \(\omega_t = -\mathbb{E}[Y^1_t | \mathcal{F}^0_t]\).

The above observation motivates us to consider the following FBSDE:

\[
\begin{align*}
  dX_t &= \left(\hat{\alpha}(Y^i_t, -\mathbb{E}[Y^j_t | \mathcal{F}^0_t]) + l(t, -\mathbb{E}[Y^j_t \mathcal{F}_t], c^0_t, c_t)\right)dt \\
  &\quad + \sigma_0(t, -\mathbb{E}[Y^j_t | \mathcal{F}^0_t], c^0_t, c_t)dw^0_t + \sigma(t, -\mathbb{E}[Y^j_t | \mathcal{F}_t], c^0_t, c_t)dw^1_t, \\
  dY_t &= -\partial_x f(t, X_t, -\mathbb{E}[Y^j_t | \mathcal{F}_t], c^0_t, c_t)dt + Z^0_tdw^0_t + Z^1_tdw^1_t,
\end{align*}
\]

with \(X_0 = \xi\) and

\[
Y_T = \frac{\mathbb{b}}{1 - \mathbb{b}} \mathbb{E}\left[\partial_x g(X_T, c^0_T, c_T) | \mathcal{F}^0_T\right] + \partial_x g(X_T, c^0_T, c_T).
\]

To simplify the notation, we have omitted the superscript 1 from \(Y^1, X^1, \xi^1\) and \(c^1\). Let us remark on the terminal condition. \(Y_T = \partial_x g(X_T, -\mathbb{E}[Y^j_T | \mathcal{F}^0_T], c^0_T, c_T)\) is not yet fully specified. Taking the conditional expectation in the both sides gives

\[
\mathbb{E}[Y_T | \mathcal{F}^0_T] = \mathbb{b}\mathbb{E}[Y_T | \mathcal{F}^0_T] + \mathbb{E}\left[\partial_x g(X_T, c^0_T, c_T) | \mathcal{F}^0_T\right],
\]

which implies \(\mathbb{E}[Y_T | \mathcal{F}^0_T] = \frac{1}{1 - \mathbb{b}} \mathbb{E}\left[\partial_x g(X_T, c^0_T, c_T) | \mathcal{F}^0_T\right]\). Substituting this expression for \(\mathbb{E}[Y_T | \mathcal{F}^0_T]\) in \(\partial_x g\), we get the above specification of the terminal condition.

This is the FBSDE we are going to study in the following. It is of McKean-Vlasov type with common noise, and similar to the FBSDEs relevant for the extended mean field games. In the following, we are going to prove the existence of a unique solution to the above FBSDE under
We now investigate the solvability of the FBSDE derived in the last section.

4 Solvability of the mean-field FBSDE

Remark 5.1. Although it is weaker than (3.2), by the factor $N^{-1}$, this is the standard convention of the market clearing condition used in the economics literature dealing with infinite number of agents. See, for example, Föllmer (1974) [16] and references therein. Note that, if $(\omega_t)_{t \in [0,T]} \in \mathbb{H}^2(\mathbb{F}^0; \mathbb{R}^n)$ with $\omega_T \in L^2(\mathbb{F}_T^0; \mathbb{R}^n)$ is given arbitrary, then the quantity in the left-hand side, which is the average of the excess demand, has a non-zero limit of $L^2$-moment. See also the discussion in Remark 5.1.

4.1 Unique existence for small $T$

Assumption 4.1. For any $(t, x, c^0, c) \in [0,T] \times (\mathbb{R}^n)^3$ and any $\omega, \omega' \in \mathbb{R}^n$, the coefficient functions $l, \sigma_0, \sigma$ and $\bar{f}$ satisfy, with $L$ and another nonnegative constant $L_\omega$,

$$|l(t, \omega, c^0, c) - l(t, \omega', c^0, c)| \leq L|\omega - \omega'|,$$

$$|\sigma_0(t, \omega, c^0, c) - \sigma_0(t, \omega', c^0, c)| \leq L|\omega - \omega'|,$$

$$|\sigma(t, \omega, c^0, c) - \sigma(t, \omega', c^0, c)| \leq L|\omega - \omega'|.$$

Due to the Lipschitz continuity and the absence of $(Z^0, Z)$ in the diffusion coefficients of the forward SDE, we have the following short-term existence result.

Theorem 4.1. Under Assumptions [3.3] and [4.1], there exists some constant $\tau > 0$ which depends only on $(L, L_\omega, b)$ such that for any $T \leq \tau$, there exists a unique strong solution $(X, Y, Z^0, Z) \in S^2(\mathbb{F}^1; \mathbb{R}^n) \times S^2(\mathbb{F}^1; \mathbb{R}^n) \times \mathbb{H}^2(\mathbb{F}^1; \mathbb{R}^{n \times d}) \times \mathbb{H}^2(\mathbb{F}^1; \mathbb{R}^{n \times d})$ to the FBSDE (4.1).
Proof. Although there exist terms involving $\mathbb{E}[Y_t|\mathcal{F}_t^0]$, one can adopt the standard technique for the Lipschitz FBSDE. See, for example, the proof for [44 Theorem 1.45]. \qed

4.2 Unique existence for general $T$

In order to obtain the existence result for general $T$, we are going to apply the technique developed by Peng & Wu [37]. In the case of the standard optimization problem, the joint convexity in the state and control variables combined with strict convexity in the control variable are enough to obtain the unique existence. Interestingly however, we need a strict convexity also in the state variable $X$ in our problem. As we shall see, this is because the term $-\mathbb{E}[Y_t|\mathcal{F}_t^0]$ which appears due to the clearing condition weakens the convexity.

**Assumption 4.2.**

(i) The functions $\sigma_0$ and $\sigma$ are independent of the argument $\varpi$.

(ii) For any $t \in [0, T]$, any random variables $x, x', c^0, c \in \mathbb{L}^2(\mathcal{F}; \mathbb{R}^n)$ and any sub-$\sigma$-field $\mathcal{G} \subset \mathcal{F}$, the function $l$ satisfies the monotone condition, with some positive constant $\gamma_l > 0$,

$$\mathbb{E}\left[ \left( l(t, \mathbb{E}[x|\mathcal{G}], c^0, c) - l(t, \mathbb{E}[x'|\mathcal{G}], c^0, c), x - x' \right) \right] \geq \gamma_l \mathbb{1}_{\{L_\varpi > 0\}} \mathbb{E}[|x - x'|^2] .$$

(iii) There exists a strictly positive constant $\gamma$ satisfying $0 < \gamma \leq \left( \gamma_f - \frac{L_\varpi^2}{4\gamma_f} \right) \wedge \gamma^g$. Moreover, for any $x, x', c^0, c \in \mathbb{L}^2(\mathcal{F}; \mathbb{R}^n)$ and any sub-$\sigma$-field $\mathcal{G} \subset \mathcal{F}$, the function $\overline{g}$ satisfies

$$\gamma^g \mathbb{E}[|x - x'|^2] + \frac{b}{1 - b} \mathbb{E}\left[ \left( \mathbb{E}[\partial_x \overline{g}(x, c^0, c) - \partial_x \overline{g}(x', c^0, c)|\mathcal{G}], x - x' \right) \right] \geq \gamma \mathbb{E}[|x - x'|^2] .$$

**Remark 4.1.** If $l$ and $\partial_x \overline{g}$ have separable forms such as $h(x) + h^c(c^0, c)$ with some functions $h$ and $h^c$, then the conditions (ii) and (iii) are satisfied when the function $h$ is monotone. Economically speaking, the condition (ii) roughly implies that the demands from the individual OTC clients for the securities decrease when their market prices rise.

The next theorem is the first main existence result.

**Theorem 4.2.** Under Assumptions 3.1, 4.1 and 4.2, there exists a unique strong solution $(X, Y, Z^0, Z) \in \mathbb{S}^2(\mathcal{F}^1; \mathbb{R}^n) \times \mathbb{S}^2(\mathcal{F}^1; \mathbb{R}^n) \times \mathbb{H}^2(\mathcal{F}^1; \mathbb{R}^{n \times d}) \times \mathbb{H}^2(\mathcal{F}^1; \mathbb{R}^{n \times d})$ to the FBSDE [41].

Proof. In order to simplify the notation, let us define the functionals $B, F$ and $G$ for any $y, x, c^0, c \in \mathbb{L}^2(\mathcal{F}; \mathbb{R}^n)$ by

$$B(t, y, c^0, c) := \left( -\overline{N}(y - \mathbb{E}[y|\mathcal{F}_t^0]) + l(t, -\mathbb{E}[y|\mathcal{F}_t^0], c^0, c) \right) ,$$

$$F(t, y, c^0, c) := -\partial_x \overline{f}(t, x, -\mathbb{E}[y|\mathcal{F}_t^0], c^0, c) ,$$

$$G(x, c^0, c) := \frac{b}{1 - b} \mathbb{E}\left[ \partial_x \overline{g}(x, c^0, c)|\mathcal{F}_t^0 \right] + \partial_x \overline{g}(x, c^0, c) . \quad (4.2)$$

With the convention $\Delta y := y - y', \Delta x := x - x'$, one can easily confirms

$$\mathbb{E}\left[ \left( B(t, y, c^0, c) - B(t, y', c^0, c), \Delta y \right) \right] \leq -\gamma_l \mathbb{1}_{\{L_\varpi > 0\}} \mathbb{E}[\Delta y|^2] ,$$

$$\mathbb{E}\left[ \left( F(t, y, c^0, c) - F(t, y', c^0, c), \Delta x \right) \right] \leq -\left( \gamma_f - \frac{L_\varpi^2}{4\gamma_f} \right) \mathbb{E}[\Delta x|^2] + \gamma \mathbb{1}_{\{L_\varpi > 0\}} \mathbb{E}[\Delta y|^2] ,$$

$$\mathbb{E}\left[ \left( G(x, c^0, c) - G(x', c^0, c), \Delta x \right) \right] \geq \gamma \mathbb{E}[\Delta x|^2] . \quad (4.3)$$
where the first estimate follows from Assumption 4.2(ii) and Jensen’s inequality, the second from Assumptions 4.1(iv), 4.3 and Cauchy-Schwarz inequality. The third one is the direct consequence of Assumption 4.2(iii).

We first make the following hypothesis: there exists some constant $c \in [0,1)$ such that, for any $(I^i_t)_{t \geq 0}$, $(I^f_t)_{t \geq 0}$ in $H^2(L^1; \mathbb{R}^n)$ and any $\gamma \in L^2(F^1; \mathbb{R}^n)$, there exists a unique solution $(x^0, y^0, z^0, x^0) \in S^2(F^1; \mathbb{R}^n) \times S^2(F^1; \mathbb{R}^n) \times H^2(F^1; \mathbb{R}^n \times d^2) \times H^2(F^1; \mathbb{R}^n \times d^2)$ to the FBSDE:

$$
\begin{align*}
\frac{dx^0_t}{dt} &= \frac{\partial B(t,y^0_t,c^0_t,c_t) + I^i_t}{\partial t} dt + \sigma_0(t,c^0_t,c_t) dW^0_t + \sigma(t,c^0_t,c_t) dW^1_t, \\
\frac{dy^0_t}{dt} &= -\left((1-q)\gamma x^0_t - \partial F(t,x^0_t,y^0_t,c^0_t,c_t) + I^f_t\right) dt + z^0_t dW^0_t + z^0_t dW^1_t,
\end{align*}
$$

(4.4)

with $x^0_0 = \xi$ and $y^0_0 = \partial G(x^0_0,c^0_0,c_0) + (1-q)x^0_T + \eta$. Note that when $q = 0$ we have a decoupled set of SDE and BSDE and hence the hypothesis trivially holds. Our goal is to extend the $q$ up to 1 by following Peng-Wu’s continuation method [37]. Now, for an arbitrary set of inputs $(x, y, z, z) \in S^2(F^1; \mathbb{R}^n) \times S^2(F^1; \mathbb{R}^n \times d^2) \times H^2(F^1; \mathbb{R}^n \times d^2)$ and constant $c \in (0,1)$, consider

$$
\begin{align*}
\frac{dX_t}{dt} &= \left[\partial B(t,Y_t,c^0_t,c_t) + \gamma B(t,y^0_t,c^0_t,c_t) + I^i_t\right] dt + \sigma_0(t,c^0_t,c_t) dW^0_t + \sigma(t,c^0_t,c_t) dW^1_t, \\
\frac{dY_t}{dt} &= -\left((1-q)\gamma X_t - \partial F(t,x^0_t,y^0_t,c^0_t,c_t) + \gamma \theta x_t - F(t,x_t,y_t,c^0_t,c_t) + I^f_t\right) dt + Z^0_t dW^0_t + Z^0_t dW^1_t,
\end{align*}
$$

(4.5)

with $X_0 = \xi$ and $Y_T = \partial G(X_T,c^0_T,c_T) + (1-q)X_T + \gamma \theta x_T - F(t,x_T,y_T,c^0_T,c_T) + \gamma \theta x_T - F(t,x_T,y_T,c^0_T,c_T) + I^f_T + \eta$. The existence of the solution $(X,Y,Z^0,Z) \in S^2 \times S^2 \times H^2 \times H^2$ is guaranteed by the previous hypothesis. We are going to prove the map $(x, y, z, z) \mapsto (X,Y,Z^0,Z)$ defined above becomes strict contraction when $c > 0$ is chosen small enough.

For two sets of inputs $(x, y, z, z)$ and $(x', y', z', z')$, let us denote the corresponding solutions to (4.5) by $(X,Y,Z^0,Z)$ and $(X',Y',Z^0',Z')$, respectively. We put $\Delta X_t := X_t - X'_t$, $\Delta Y_t := Y_t - Y'_t$ and similarly for the others. Applying Itô’s formula to $(\Delta X, \Delta Y)$ and using the estimates (4.3), we obtain

$$
\begin{align*}
\mathbb{E}\left[(\Delta X_T, \Delta Y_T)\right] &\leq -\gamma \mathbb{E}\int_0^T |\Delta X_t|^2 dt \\
&\quad + \zeta C \mathbb{E}\int_0^T \left[|\Delta Y_t|(|\Delta y_t| + \mathbb{E}[|\Delta y_t|]) + |\Delta X_t|(|\Delta x_t| + \mathbb{E}[|\Delta x_t|])\right] dt.
\end{align*}
$$

On the other hand, from the terminal condition on $\Delta Y_T$, we get

$$
\mathbb{E}\left[(\Delta X_T, \Delta Y_T)\right] \geq (\gamma + (1-q)) \mathbb{E}[|\Delta X_T|^2] - \zeta C \mathbb{E}[|\Delta X_T|(|\Delta x_T| + \mathbb{E}[|\Delta x_T|])].
$$

In both cases, the constant $C$ is $q$-independent. Let us set $\gamma := \min(1, \gamma) > 0$. Then one easily confirms $0 < \gamma_c \leq \gamma + (1-q)$ for any $q \in [0,1)$. Then the above estimates yield

$$
\begin{align*}
\gamma_c \mathbb{E}[|\Delta X_T|^2] + \int_0^T |\Delta X_t|^2 dt &\leq \zeta C \mathbb{E}[|\Delta X_T|(|\Delta x_T| + \mathbb{E}[|\Delta x_T|])] \\
&\quad + \zeta C \mathbb{E}\int_0^T \left[|\Delta Y_t|(|\Delta y_t| + \mathbb{E}[|\Delta y_t|]) + |\Delta X_t|(|\Delta x_t| + \mathbb{E}[|\Delta x_t|])\right] dt.
\end{align*}
$$

12
Using Young’s inequality and a new constant $C$, we get

$$
E[|\Delta X_T|^2] + E \int_0^T |\Delta X_t|^2 dt \leq \zeta C E \int_0^T (|\Delta Y_t|^2 + (|\Delta x_t|^2 + |\Delta y_t|^2)) dt + \zeta C E[|\Delta X_T|^2]. \quad (4.6)
$$

Treating $X, X'$ as inputs, the standard estimates for the Lipschitz BSDEs (see, for example, Theorem 4.2.3) gives

$$
E \left[ \sup_{t \in [0,T]} |\Delta Y_t|^2 + \int_0^T (|\Delta Z_t^0|^2 + |\Delta Z_t|^2) dt \right] \leq C E \left[ |\Delta X_T|^2 + \int_0^T (|\Delta x_t|^2 + |\Delta y_t|^2) dt \right].
$$

Combining with (4.6) and choosing $\zeta > 0$ small, we obtain

$$
E \left[ \sup_{t \in [0,T]} |\Delta Y_t|^2 + \int_0^T (|\Delta Z_t^0|^2 + |\Delta Z_t|^2) dt \right] \leq \zeta C E \left[ |\Delta X_T|^2 + \int_0^T (|\Delta x_t|^2 + |\Delta y_t|^2) dt \right]. \quad (4.7)
$$

By the similar procedures, we also have

$$
E \left[ \sup_{t \in [0,T]} |\Delta X_t|^2 \right] \leq \zeta C E \left[ |\Delta X_T|^2 + \int_0^T (|\Delta x_t|^2 + |\Delta y_t|^2) dt \right]. \quad (4.8)
$$

From (4.7) and (4.8), we obtain with $C = C(L, \overline{X}, \gamma_c, T, \zeta)$

$$
E \left[ \sup_{t \in [0,T]} |\Delta X_t|^2 + \sup_{t \in [0,T]} |\Delta Y_t|^2 + \int_0^T (|\Delta Z_t^0|^2 + |\Delta Z_t|^2) dt \right] \leq \zeta C E \left[ \sup_{t \in [0,T]} |\Delta x_t|^2 + \sup_{t \in [0,T]} |\Delta y_t|^2 + \int_0^T (|\Delta z_t^0|^2 + |\Delta z_t|^2) dt \right],
$$

where $C$ is decreasing as $\zeta$ goes to zero. Thus there exists $\zeta > 0$, being independent of the size of $\rho$, that makes the map $(x, y, z^0, z) \mapsto (X, Y, Z^0, Z)$ strict contraction. Therefore the initial hypothesis holds true for $(\rho + \zeta)$, which establishes the existence. The uniqueness follows from the next proposition.

**Proposition 4.1.** Given two set of inputs $(\xi, c^0, c), (\xi', c'^0, c')$, coefficients $(b, \Lambda), (b', \Lambda')$ and the coefficient functions $(l, \sigma_0, \sigma, \overline{T}, \overline{F}), (l', \sigma_0', \sigma', \overline{T}', \overline{F}')$ satisfying Assumptions 2.1, 4.1 and 4.2, let us denote the corresponding solutions to (4.1) by $(X, Y, Z^0, Z)$ and $(X', Y', Z'^0, Z')$, respectively. We also define the functionals $(B, F, G)$ and $(B', F', G')$ by (4.2), with corresponding coefficients, respectively. Then, we have the following stability result:

$$
E \left[ \sup_{t \in [0,T]} |\Delta X_t|^2 + \sup_{t \in [0,T]} |\Delta Y_t|^2 + \int_0^T (|\Delta Z_t^0|^2 + |\Delta Z_t|^2) dt \right] \leq C E \left[ |\Delta \xi|^2 + |\delta G|^2 + \int_0^T (|\delta F(t)|^2 + |\delta B(t)|^2 + |\delta \sigma_0(t)|^2 + |\delta \sigma(t)|^2) dt \right],
$$

13
where \( C \) is a constant depending only on \( T \) as well as the Lipschitz constants of the system, and

\[
\begin{align*}
\delta B(t) &:= B(t, Y'_t, c'_t, c_t) - B'(t, Y'_t, c'_t, c_t), \\
\delta F(t) &:= F(t, X_t, Y_t, c_t) - F'(t, X'_t, Y'_t, c'_t, c'_t), \\
(\delta\sigma_0, \delta\sigma)(t) &:= (\sigma_0(t, c'_0, c_t) - \sigma'_0(t, c'_0, c'_t), \sigma(t, c'_t, c_t) - \sigma'(t, c'_t, c'_t)), \\
\delta G &:= G(X'_t, c'_t, c_t) - G'(X'_t, c'_t, c_t),
\end{align*}
\]

and \( \Delta \xi := \xi - \xi' \), \( \Delta X_t := X_t - X'_t \) and similarly for the other variables.

**Proof.** Let us put \( \Delta B(t) := B(t, Y'_t, c'_t, c_t) - B(t, Y'_t, c'_t, c_t) \), \( \Delta F(t) := F(t, X_t, Y_t, c_t) - F(t, X'_t, Y'_t, c'_t, c'_t) \) and \( \Delta G := G(X'_t, c'_t, c_t) - G(X'_t, c'_t, c_t) \). We get by Itô’s formula to \( \langle \Delta X, \Delta Y \rangle \),

\[
\mathbb{E}[\langle \Delta X_T, \Delta G + \delta G \rangle] = \mathbb{E}[\langle \Delta \xi, \Delta Y_0 \rangle + \int_0^T (\langle \delta F(t), \Delta X_t \rangle + \langle \delta B(t), \Delta Y_t \rangle \\
+ \langle \delta\sigma_0(t), \Delta Z^0_t \rangle + \langle \delta\sigma(t), \Delta Z_t \rangle + (\langle \Delta F(t), \Delta X_t \rangle + \langle \Delta B(t), \Delta Y_t \rangle)dt] .
\]

Using (4.3), we obtain

\[
\gamma \mathbb{E}[\langle \Delta X_T \rangle^2 + \int_0^T |\Delta X_t|^2 dt] \leq \mathbb{E}[\langle \Delta \xi, \Delta Y_0 \rangle - \langle \Delta X_T, \delta G \rangle \\
+ \int_0^T (\langle \delta F(t), \Delta X_t \rangle + \langle \delta B(t), \Delta Y_t \rangle + \langle \delta\sigma_0(t), \Delta Z^0_t \rangle + \langle \delta\sigma(t), \Delta Z_t \rangle)dt] .
\]

On the other hand, the standard estimates for Lipschitz SDEs and BSDEs give

\[
\mathbb{E}\left[ \sup_{t \in [0,T]} |\Delta Y_t|^2 + \int_0^T (|\Delta Z^0_t|^2 + |\Delta Z_t|^2) dt \right]
\leq C\mathbb{E}\left[ |\delta G|^2 + \int_0^T |\delta F(t)|^2 dt \right] + C\mathbb{E}\left[ |\Delta X_T|^2 + \int_0^T |\Delta X_t|^2 dt \right] ,
\]

(4.10)

\[
\mathbb{E}\left[ \sup_{t \in [0,T]} |\Delta X_t|^2 \right] \leq C\mathbb{E}\left[ |\Delta \xi|^2 + \int_0^T [|\delta B(t)|^2 + |\delta\sigma_0(t)|^2 + |\delta\sigma(t)|^2] dt \right] + C\mathbb{E}\int_0^T |\Delta Y_t|^2 dt .
\]

Combining the above inequalities (4.9) and (4.10) gives

\[
\mathbb{E}\left[ \sup_{t \in [0,T]} |\Delta X_t|^2 + \sup_{t \in [0,T]} |\Delta Y_t|^2 + \int_0^T (|\Delta Z^0_t|^2 + |\Delta Z_t|^2) dt \right]
\leq C\mathbb{E}\left[ |\Delta \xi|^2 + |\delta G|^2 + \int_0^T [|\delta F(t)|^2 + |\delta B(t)|^2 + |\delta\sigma_0(t)|^2 + |\delta\sigma(t)|^2] dt \right]
+ C\mathbb{E}\left[ \langle \Delta \xi, \Delta Y_0 \rangle - \langle \Delta X_T, \delta G \rangle + \int_0^T (\langle \delta F(t), \Delta X_t \rangle + \langle \delta B(t), \Delta Y_t \rangle + \langle \delta\sigma_0(t), \Delta Z^0_t \rangle + \langle \delta\sigma(t), \Delta Z_t \rangle) dt \right] .
\]

Now simple application of Young’s inequality establishes the claim.

**Corollary 4.1.** Under Assumptions \( \mathcal{A}_3, \mathcal{A}_4 \) and \( \mathcal{A}_7 \), the solution \((X, Y, Z^0, Z)\) to the FBSDE
satisfies the following estimate:

\[
\mathbb{E}\left[ \sup_{t \in [0,T]} |X_t|^2 + \sup_{t \in [0,T]} |Y_t|^2 + \int_0^T (|Z_t|^2 + |Z_t|^2) dt \right] \leq C \mathbb{E}\left[ |\xi|^2 + |\partial_x \bar{f}(0, c^0_T, c_T)|^2 \right. \\
\left. + \int_0^T \left( |\partial_x \bar{f}(t, 0, 0, c^0_t, c_t)|^2 + |l(t, 0, c^0_t, c_t)|^2 + |(\sigma_0, \sigma)(t, c^0_t, c_t)|^2 \right) dt \right],
\]

where \( C \) is a constant depending only on \( T, b \) and Lipschitz constants of the system.

Proof. By quick inspection of the proof for Proposition 4.1, one sees that we have used properties of the coefficient functions given in Assumptions 3.1, 4.1 and 4.2 only for \((l, \sigma_0, \sigma, \bar{f}, \bar{g})\). In fact, we would have gotten the same conclusion in the proposition even if the coefficients \((l', \sigma_0', \sigma', \bar{f}', \bar{g}')\) were chosen arbitrarily as long as \((X', Y', Z', \bar{f}', \bar{g}') \in \mathbb{S}^2 \times \mathbb{S}^2 \times \mathbb{H}^2 \times \mathbb{H}^2\) were well-defined. In particular, by putting \(\xi'\) and \((l', \sigma_0', \sigma', \bar{f}', \bar{g}')\) all zero, we have a trivial solution \((X', Y', Z'^0, Z') = (0, 0, 0, 0)\). The desired estimate now follows from Proposition 4.1. \(\square\)

4.3 Application to securities with exogenously specified payoff

If we consider the exchange markets of bonds and futures, or other financial derivatives with maturity \(T\), those securities cease to exist at \(T\) after paying exogenously specified amount of cash \(c^0_T\). In this case, as we have mentioned in Remark 3.2, it is natural to consider with \(b = 0\) and

\[
g(x, c^0) = \bar{g}(x, c^0) := -\langle c^0, x \rangle,
\]

since there is no reason to put penalty on the outstanding volume at \(T\). In this case, the terminal function \(g\) in (4.11) does not have the strict convexity. Fortunately, even in this case, we can prove the unique existence as well as the stability result of the same form.

Assumption 4.3.
The same conditions as in Assumption 4.2 except (iii), which is replaced by

(iii)' \(\gamma := \gamma^J - \frac{12}{\Gamma^J}\) is strictly positive and the terminal function \(g\) is given by (4.11) with \(b = 0\).

Proposition 4.2. Under Assumptions 3.1, 4.1 and 4.3, there exists a unique strong solution \((X, Y, Z^0, Z) \in \mathbb{S}^2(\mathbb{F}^1; \mathbb{R}^n) \times \mathbb{S}^2(\mathbb{F}^1; \mathbb{R}^n) \times \mathbb{H}^2(\mathbb{F}^1; \mathbb{R}^{n \times d}) \times \mathbb{H}^2(\mathbb{F}^1; \mathbb{R}^{n \times d})\) to the FBSDE (4.1). Moreover, the same form of stability and \(L^2\) estimates given in Proposition 4.1 and Corollary 4.1 hold.

Proof. Note that, in this case, the terminal condition for the BSDE is independent of \(X_T\). Thus, as in [37] Theorem 2.3], we put \(y^J_T = Y_T = -c^0_T\) in (4.4) and (4.5), respectively. Using the fact that \(\langle AX_T, AY_T \rangle = 0\), one can follow the same arguments to get the desired result. The proof of the stability result can also be done in almost exactly the same way. \(\square\)

Before closing the section, let us give a simple example of \(n\) bonds which have coupon streams represented by \(n\)-dimensional process \((c^0_t)_{t \in [0,T]}\) as well as the unit principal payment at the maturity \(T\). We introduce two measurable functions \(p : [0, T] \to \mathbb{R}^n\) and \(q : [0, T] \times \mathbb{R}^n \to \mathbb{R}^n\) satisfying

\[
|p(t)| \leq C, \quad |q(t, c)| \leq C(1 + |c|)
\]

with some constant \(C > 0\) for any \((t, c) \in [0, T] \times \mathbb{R}^n\).
Corollary 4.2. Suppose that $\sigma_0, \sigma$ are constant matrices with appropriate dimensions, $c_i^0 = (1, \cdots, 1)^T$ the n-dimensional vector, the functions $p$ and $q$ as above, and that the terminal cost is given by \( (\mathbf{1.1}) \). Moreover, the functions of running cost $J: [0, T] \times (\mathbb{R}^n)^3 \to \mathbb{R}$ as well as the OTC order flows $l: [0, T] \times \mathbb{R}^n \to \mathbb{R}$ are given by
\[
J(t, x, c^0, c) := -(c^0, x) + \frac{\theta}{2} |x - q(t, c)|^2, \\
l(t, \varpi) := \zeta(\varpi - p(t)),
\]
respectively, where $\theta, \zeta$ are positive constants. Then, there exists a unique solution to the FBSDE \( (\mathbf{1.1}) \) with corresponding coefficients.

In the above example, except the noise terms, the OTC clients of each agent tend to sell the $i$th bond (and hence increase the storage level of the agents) when $\varpi_i \geq p^i(t)$. The function $q(t, c)$ denotes some target level of the storage depending on the idiosyncratic information $c$.

5 Asymptotic Market Clearing

We are now ready to investigate if our FBSDE \( (\mathbf{1.1}) \) actually provides an approximate of the market price and if so, how accurate it is. By Theorem 3.1 if we use $(-E[Y_t|]\mathbb{F}_t^0)_{t \in [0, T]}$ as the input $(\varpi_t)_{t \in [0, T]}$, where $(Y_t)_{t \in [0, T]}$ is the unique solution to the FBSDE \( (\mathbf{4.1}) \) with the convention $\xi = \xi^1$ and $c = c^1$, the optimal strategy of the individual agent is given by
\[
\hat{\alpha}^i_{\text{inf}}(t) := \hat{\alpha}(Y^i_t, -E[Y_t|]\mathbb{F}_t^0) = -\Lambda(Y^i_t - E[Y_t|]\mathbb{F}_t^0))
\]
where $(Y^i_t)_{t \in [0, T]}$ is the solution to \( (\mathbf{4.4}) \) with $(\varpi_t = -E[Y_t|]\mathbb{F}_t^0)_{t \in [0, T]}$. The next theorem shows that the market clearing condition in the large-$N$ limit \( (\mathbf{3.5}) \) holds.

Theorem 5.1. If the conditions for Theorem 4.1, Theorem 4.2 or Proposition 4.2 are satisfied then we have
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \hat{\alpha}^i_{\text{inf}}(t) = 0.
\]
Moreover if there exists some constant $\Gamma$ such that $\sup_{t \in [0, T]} E[Y_t]^q \leq \Gamma < \infty$ for some $q > 4$, then there exists some constant $C$ independent of $N$ such that
\[
E \int_0^T \frac{1}{N} \sum_{i=1}^{N} \hat{\alpha}^i_{\text{inf}}(t)^2 dt \leq C T^2 \epsilon_N,
\]
where $\epsilon_N := N^{-2/\max(n, 4)} (1 + \log(N) 1_{\{n=4\}})$.

Proof. Let us consider the following set of FBSDEs with $1 \leq i \leq N$ on the filtered probability space $(\Omega, \mathcal{F}, \mathbb{P}; \mathbb{F})$ constructed in Section 2
\[
x_i(t) = \left(-\Lambda(Y^i_t - E[Y^i_t|]\mathbb{F}_t^0)) + l(t, -E[Y^i_t|]\mathbb{F}_t^0, c^0_t, c^i_t)\right) dt \\
+ \sigma_0(t, -E[Y^i_t|]\mathbb{F}_t^0, c^0_t, c^i_t) dW^0_t + \sigma(t, -E[Y^i_t|]\mathbb{F}_t^0, c^0_t, c^i_t) dW^i_t, \\
y_i(t) = -\partial_x J(t, x^i_t, -E[Y^i_t|]\mathbb{F}_t^0, c^0_t, c^i_t) dt + Z^i_0 dW^0_t + Z^i_t dW^i_t,
\]
with $X^i_0 = \xi^i$ and
\[
Y^i_t = \frac{b}{1 - \theta} \mathbb{E} \left[ \partial_x g(X^i_T, c^0_T, c^i_T) \big| \mathcal{F}^0_T \right] + \partial_x g(X^i_T, c^0_T, c^i_T).
\]

Thanks to the existence of unique strong solution, Yamada-Watanabe Theorem for FBSDEs (see, [14, Theorem 1.33]), there exists some measurable function $\Phi$ such that for every $1 \leq i \leq N$,
\[
(X^i_t, Y^i_t)_{t \in [0,T]} = \Phi \left( (\xi^i_t)_{t \in [0,T]}, (W^i_t)_{t \in [0,T]}, (c^i_t)_{t \in [0,T]}, (W^i_t)_{t \in [0,T]} \right).
\]

Hence, conditionally on $\mathcal{F}^0$, the set of processes $(X^i_t, Y^i_t)_{t \in [0,T]}$ with $1 \leq i \leq N$ are independently and identically distributed. In particular, we have $\mathbb{P}$-a.s.
\[
\mathbb{E}[Y^i_t | \mathcal{F}^0_t] = \mathbb{E}[Y^i_t], \quad \forall t \in [0, T],
\]
\[
\mathbb{E}[\partial_x g(X^i_t, c^0_t, c^i_t) | \mathcal{F}^0_t] = \mathbb{E}[\partial_x g(X^i_t, c^0_t, c_t) | \mathcal{F}^0_t].
\] (5.3)

Note that, under the convention $\xi^1 = \xi$ and $c^1 = c$, we actually have $(X^1, Y^1) = (X, Y)$. From (5.3), we conclude that $(X^i_t, Y^i_t, Z^i_t)_{t \in [0,T]} = (X^i_t, Y^i_t, Z^i_t)_{t \in [0,T]}$ in $S^2(\mathbb{F}^2) \times S^2(\mathbb{F}^2) \times \mathbb{H}^2(\mathbb{F}^2) \times \mathbb{H}^2(\mathbb{F}^2)$. Therefore,
\[
\frac{1}{N} \sum_{i=1}^N \hat{\alpha}_{inf}^i(t) = -\mathbb{X} \left( \frac{1}{N} \sum_{i=1}^N Y^i_t - \mathbb{E}[Y^i_t | \mathcal{F}^0_t] \right).
\] (5.4)

We can easily check that
\[
\mathbb{E} \left[ W_2 \left( \frac{1}{N} \sum_{i=1}^N \delta_{Y^i_t}, \mathcal{L}(Y^i_t | \mathcal{F}^0_t) \right)^2 \big| \mathcal{F}^0_t \right] \leq \frac{2}{N} \sum_{i=1}^N \mathbb{E}[|Y^i_t|^2 | \mathcal{F}^0_t] + 2 \mathbb{E}[|Y^i_t|^2 | \mathcal{F}^0_t] = 4 \mathbb{E}[|Y^1_t|^2 | \mathcal{F}^0_t].
\]

Since $(Y^i_t)_{1 \leq i \leq N}$ are $\mathcal{F}^0_t$-conditionally independently and identically distributed and also $Y^1 \in S^2$, the same arguments leading to (2.14) in [14] imply that the pointwise convergence holds:
\[
\lim_{N \to \infty} \mathbb{E} \left[ W_2 \left( \frac{1}{N} \sum_{i=1}^N \delta_{Y^i_t}, \mathcal{L}(Y^1_t | \mathcal{F}^0_t) \right)^2 \big| \mathcal{F}^0_t \right] = 0.
\] (5.5)

We are now going to show that the set of functions, $(f_N)_{N \in \mathbb{N}}$ defined by
\[
[0,T] \ni t \mapsto f_N(t) := \mathbb{E} \left[ W_2 \left( \overline{\mu}_t, \mu_t \right)^2 \right] \in \mathbb{R}
\]
with $\overline{\mu}_t := \frac{1}{N} \sum_{i=1}^N \delta_{Y^i_t}$ and $\mu_t := \mathcal{L}(Y^1_t | \mathcal{F}^0_t)$ are precompact in the set $C([0,T]; \mathbb{R})$ endowed with the topology of uniform convergence. In fact, uniformly in $N$,
\[
\sup_{t \in [0,T]} |f_N(t)| \leq 4 \sup_{t \in [0,T]} \mathbb{E}[|Y^1_t|^2] \leq C < \infty
\] (5.6)

where $C$ is given by the estimate in Corollary 4.1. Moreover, for any $0 \leq t, s \leq T$, Cauchy-
The estimate can be proved as follows. For any $\mu, \nu \in \mathcal{P}_1(\mathbb{R}^n)$, Jensen’s inequality implies
\[
\left| \int_{\mathbb{R}^n} x \mu(dx) - \int_{\mathbb{R}^n} y \nu(dy) \right| = \int_{\mathbb{R}^n \times \mathbb{R}^n} (x - y) \pi(dx, dy) \leq \int_{\mathbb{R}^n \times \mathbb{R}^n} |x - y| \pi(dx, dy)
\]
for any coupling $\pi \in \Pi_1(\mu, \nu)$ with marginals $\mu$ and $\nu$. Taking infimum over $\pi \in \Pi_1(\mu, \nu)$, the definition of Wasserstein distance in (2.1) gives
\[
\left| \int_{\mathbb{R}^n} x \mu(dx) - \int_{\mathbb{R}^n} y \nu(dy) \right| \leq W_1(\mu, \nu).
\]
Substituting $\frac{1}{N} \sum_{i=1}^N \delta_{X_i}$ and $\mathcal{L}(Y^i_t|\mathcal{F}^0_t)$ into $\mu$ and $\nu$ in the above relation, we obtain the desired inequality. Eq. (5.4) and the obvious relation $W_1(\mu, \nu) \leq W_2(\mu, \nu)$ for $\mu, \nu \in \mathcal{P}_2(\mathbb{R}^n)$ give
\[
\mathbb{E} \int_0^T \left| \frac{1}{N} \sum_{i=1}^N \delta_{X_i}(t) \right|^2 dt \leq C \sup_{t \in [0, T]} \mathbb{E} \left[ W_2 \left( \frac{1}{N} \sum_{i=1}^N \delta_{X_i}, \mathcal{L}(Y^i_t|\mathcal{F}^0_t) \right)^2 \right].
\] (5.8)

The first conclusion now follows from (5.7). The latter claims directly follows from the expression (5.8) and the (Fourth Step) in the proof of [14, Theorem 2.12].

Theorem 5.1 justifies our intuitive understanding and a special type of FBSDEs (4.11) derived in Section 3 as a reasonable model to approximate the market clearing price. When there exists higher integrability, Glivenko-Cantelli convergence theorem in the Wasserstein distance even
provides a specific order $\epsilon_N$ of convergence in terms of the number of agents $N$ (Eq. 5.2). See the discussions in [13] Theorem 5.8, Remark 5.9 for more details.

Remark 5.1. In [22], we have shown that it is indeed possible to construct the price process $(\pi_i^{(N)})_{t \in [0,T]}$ satisfying the market clearing condition (3.2) even when $N$ is finite, once we impose appropriate monotone conditions and also relax the information structure so that every agent $i$ has the perfect knowledge including idiosyncratic shocks to the other agents, $j \in \{1, \cdots, N\}, j \neq i$. We also need to assume that every agents behave as a price taker. Interestingly, we showed that $(\pi_i^{(N)})_{t \in [0,T]}$ strongly converges to the process $(-E[Y_t|\mathcal{F}_t^0])_{t \in [0,T]}$ studied in the current paper in the large-$N$ limit. Moreover, the idiosyncratic information to the other agents becomes irrelevant in the same limit, since the market price becomes adapted to $\mathcal{F}^0$ representing the common information. This observation further supports our claim that $(-E[Y_t|\mathcal{F}_t^0])_{t \in [0,T]}$ gives a reasonable approximation of the market price when the number of agents $N$ is large enough. These contents are closely related to the backward propagation of chaos. See, in particular, [22] Remark 4.3 and references therein.

Remark 5.2. Consider the situation treated in Proposition 4.2, for example, a market model of a Futures contract. If the contract pays unit amount of the underlying asset per contract whose value is exogenously given by $c_0^T$, our mean-field limit model (4.1) gives $Y_T = -c_0^T$. This means that the modeled Futures price satisfies $\tilde{\pi}_T = -E[Y_T|\mathcal{F}_T^0] = c_0^T$, which guarantees the convergence of the modeled price to the value of the underlying asset at the maturity $T$. This is a crucially important feature that any market model of this type of securities must satisfy.

6 Extension to Multiple Populations

The main limitation of the last model is that there exists only one type of agents who share the common cost functions as well as the coefficient functions for their state dynamics. Interestingly, it is rather straightforward to extend the model to the situation with multiple populations, where the agents in each population share the same cost and coefficient functions but they can be different population by population. From the perspective of the practical applications, this is a big advantage since we can analyze, for example, the interactions between the Sell-side and Buy-side institutions for financial applications, or consumers and producers for economic applications. For general issues of mean field games as well as mean field type control problems in the presence of multiple populations without common noise, see Fujii [20]. Although there exists a common noise in the current model, the conditional law only enters as a form of expectation. Therefore, as long as the system of FBSDEs is Lipschitz continuous, there exists a unique strong solution at least for small $T$. For general $T$, although it is rather difficult to find an appropriate set of assumptions, it is still possible for some simple cases. In this section, our main task is to find an appropriate limit model that extends (4.1) for multiple populations and the sufficient conditions that make appropriate monotone conditions hold, which guarantees the existence of unique solution.

In the following, we shall treat $m$ populations indexed by $p \in \{1, \cdots, m\}$. For each $p$, $N_p \geq 1$ agents are assumed to belong to the population. We denote by $(p,i)$ the ith agent in the population $p$. First, let us enlarge the probability space constructed in Section 2. In addition to $(\Omega,\mathcal{F},\mathbb{P};\mathcal{F}^0)$, we introduce $(\Omega^{p,i},\mathcal{F}^{p,i},\mathbb{P}^{p,i};\mathcal{F}^{p,i})$ with $1 \leq i \leq N_p$ and $1 \leq p \leq m$, each of which is generated by $(\xi^{p,i},\mathbf{W}^{p,i})$ with $d$-dimensional Brownian motion.
and a \( W^{p,i} \)-independent \( \mathbb{R}^n \)-valued square integrable random variable \( \xi^{p,i} \). For each \( p, \) \( (\xi^{p,i})_{i=1}^{N_p} \) are assumed to have the common law. We define \( (\Omega^{p,i}, \mathcal{F}^{p,i}, \mathbb{P}^{p,i}; \mathbb{F}^{p,i}) \) as the product of \( (\Omega^0, \mathcal{F}^0, \mathbb{P}^0; \mathbb{F}^0) \) and \( (\Omega^{p,i}, \mathcal{F}^{p,i}, \mathbb{P}^{p,i}; \mathbb{F}^{p,i}) \). Finally \( (\Omega, \mathcal{F}, \mathbb{P}; \mathbb{F}) \) is defined as a product of all the spaces \( (\Omega^0, \mathcal{F}^0, \mathbb{P}^0; \mathbb{F}^0) \) and \( (\Omega^{p,i}, \mathcal{F}^{p,i}, \mathbb{P}^{p,i}; \mathbb{F}^{p,i}) \), \( 1 \leq i \leq N_p, 1 \leq p \leq m \), and \( (\Omega^i, \mathcal{F}^i, \mathbb{P}^i; \mathbb{F}^i) \) as a product of \( (\Omega^0, \mathcal{F}^0, \mathbb{P}^0; \mathbb{F}^0) \) and \( (\Omega^{p,i}, \mathcal{F}^{p,i}, \mathbb{P}^{p,i}; \mathbb{F}^{p,i}) \) with \( 1 \leq p \leq m \). Every probability space is assumed to be complete and every filtration is assumed to be complete and right-continuously augmented to satisfy the usual conditions.

As we have done in Section 3, we first assume that the market price of \( n \) securities is given exogenously by \( \varepsilon_t \in \mathbb{H}^2(\mathbb{F}^0; \mathbb{R}^n) \) with \( \varepsilon_T \in \mathbb{L}^2(\mathbb{F}^0; \mathbb{R}^n) \). Under this setup, we consider the control problem for each \((p, i)\) agent defined by

\[
\inf_{\alpha^{p,i} \in A^{p,i}} J^{p,i}(\alpha^{p,i}),
\]

subject to the dynamic constraint:

\[
dx^{p,i}_t = \left( \alpha^{p,i}_t + \lambda \right) d\varepsilon_t + \sigma_{p,0}(t, \varepsilon_t, \xi^{p,i}) dW^{i}_t + \sigma_{p}(t, \varepsilon_t, \xi^{p,i}) dW^{p,i}_t
\]

with \( \xi^{p,i} = \xi^{p,i} \). As before we assume \((\xi^{0,i})_{t \geq 0} \in \mathbb{H}^2(\mathbb{F}^0; \mathbb{R}^n) \) with \( \xi^{0,i}_T \in \mathbb{L}^2(\mathbb{F}^0; \mathbb{R}^n) \) and \((\xi^{p,i})_{t \geq 0} \in \mathbb{H}^2(\mathbb{F}^{p,i}; \mathbb{R}^n) \) with \( \xi^{p,i}_T \in \mathbb{L}^2(\mathbb{F}^{p,i}; \mathbb{R}^n) \). In addition, within each population \( p \), the random sources \((\xi^{p,i}_t)_{t \geq 0} \) are assumed to have a common law \( 1 \leq i \leq N_p \). Admissible strategies \( A^{p,i} \) is the space \( \mathbb{H}^2(\mathbb{F}^{p,i}; \mathbb{R}^n) \). The measurable functions \( f_p : [0, T] \times (\mathbb{R}^n)^5 \rightarrow \mathbb{R}, \) \( g_p : (\mathbb{R}^n)^4 \rightarrow \mathbb{R}, \mathcal{T}_p : [0, T] \times (\mathbb{R}^n)^4 \rightarrow \mathbb{R} \) and \( \mathcal{G}_p : (\mathbb{R}^n)^3 \rightarrow \mathbb{R} \) are given by

\[
f_p(t, x, \alpha, \varepsilon, c, 0, c) := \langle \varepsilon, \alpha \rangle + \frac{1}{2} \langle \alpha, \Lambda \alpha \rangle + \mathcal{T}_p(t, x, \varepsilon, c, 0, c) ,
\]

\[
g_p(x, \varepsilon, c, 0, c) := -b(\varepsilon, x) + \mathcal{G}_p(x, c, 0, c) .
\]

**Assumption 6.1.** We assume the following conditions uniformly in \( p \in \{1, \cdots, m\} \).

(i) \( \Lambda \) is a positive definite \( n \times n \) symmetric matrix with \( \underline{\Lambda} I_{n \times n} \leq \Lambda \leq \overline{\Lambda} I_{n \times n} \) in the sense of 2nd-order form where \( \underline{\Lambda} \) and \( \overline{\Lambda} \) are some constants satisfying \( 0 < \underline{\Lambda} \leq \overline{\Lambda} \).

(ii) For any \((t, x, \varepsilon, c, 0, c)\),

\[
|\mathcal{T}_p(t, x, \varepsilon, c, 0, c)| + |\mathcal{G}_p(x, c, 0, c)| \leq L(1 + |x|^2 + |\varepsilon|^2 + |c|^2) .
\]

(iii) \( \mathcal{T}_p \) and \( \mathcal{G}_p \) are continuously differentiable in \( x \) and satisfy, for any \((t, x, x', \varepsilon, c, 0, c),\)

\[
|\partial_x \mathcal{T}_p(t, x, x', \varepsilon, c, 0, c) - \partial_x \mathcal{T}_p(t, x, \varepsilon, c, 0, c)| + |\partial_x \mathcal{T}_p(x', x, \varepsilon, c, 0, c) - \partial_x \mathcal{T}_p(x, x, \varepsilon, c, 0, c)| \leq L|x' - x| ,
\]

and

\[
|\partial_x \mathcal{G}_p(t, x, \varepsilon, c, 0, c)| + |\partial_x \mathcal{G}_p(x, \varepsilon, c, 0, c)| \leq L(1 + |x| + |\varepsilon| + |c|) .
\]
(iv) The functions $\bar{T}_p$ and $\bar{\pi}_p$ are convex in $x$ in the sense that for any $(t, x, x', \varpi, c^0, c)$,

$$
\bar{T}_p(t, x', \varpi, c^0, c) - \bar{T}_p(t, x, \varpi, c^0, c) - \langle x' - x, \partial_x \bar{T}_p(t, x, \varpi, c^0, c) \rangle \geq \frac{\gamma_f}{2} |x' - x|^2,
$$

$$
\bar{g}_p(x', c^0, c) - \bar{g}_p(x, c^0, c) - \langle x' - x, \partial_x \bar{g}_p(x, c^0, c) \rangle \geq \frac{\gamma_g}{2} |x' - x|^2,
$$

with some constants $\gamma_f, \gamma_g \geq 0$.

(v) $l_p, \sigma_{p,0}, \sigma_p$ are the measurable functions defined on $[0, T] \times (\mathbb{R}^n)^3$ and are $\mathbb{R}^n, \mathbb{R}^{n \times d^0}$ and $\mathbb{R}^{n \times d}$-valued, respectively. Moreover they satisfy the linear growth condition:

$$
|\langle (l_p, \sigma_{p,0}, \sigma_p)(t, \varpi, c^0, c) \rangle| \leq L(1 + |\varpi| + |c^0| + |c|)
$$

for any $(t, \varpi, c^0, c)$.

(vi) $b \in [0, 1)$ is a given constant.

Under Assumption 6.1, Theorem 3.1 guarantees that the control problem (6.1) for each agent $(p, i)$ is uniquely characterized by

$$
dX^{p,i}_t = \left(\hat{\alpha}_p(Y^{p,i}_t, \varpi_t) + l_p(t, \varpi_t, c^0_t, c_T^{p,i})\right)dt + \sigma_{p,0}(t, \varpi_t, c^0_t, c_T^{p,i})dW^0_t + \sigma_p(t, \varpi_t, c^0_t, c_T^{p,i})dW^{p,i}_t,
$$

$$
dY^{p,i}_t = -\partial_x \bar{T}_p(t, X^{p,i}_t, \varpi_t, c^0_t, c_T^{p,i})dt + Z_t^{p,i,0}dW^0_t + Z_t^{p,i}dW^{p,i},
$$

with $X^{p,i}_0 = \xi^{p,i}$ and $Y^{p,i}_0 = -b\varpi_T + \partial_x \bar{T}_p(X^{p,i}_T, c^0_T, c_T^{p,i})$. We have defined $\hat{\alpha}_p(y, \varpi) := -\bar{\Lambda}_p(y + \varpi)$ and $\bar{\Lambda}_p := (\Lambda_p)^{-1}$ as before. There exists a unique strong solution $(X^{p,i}_t, Y^{p,i}_t, Z^{p,i,0}_t, Z^{p,i}_t)_{t \in [0, T]} \in S^2(\mathbb{F}^{p,i}; \mathbb{R}^n) \times S^2(\mathbb{F}^{p,i}; \mathbb{R}^n) \times H^2(\mathbb{F}^{p,i}; \mathbb{R}^{n \times d^0}) \times H^2(\mathbb{F}^{p,i}; \mathbb{R}^{n \times d})$, and the optimal trading strategy for the agent $(p, i)$ is given by

$$
\hat{\alpha}_t^{p,i} = \hat{\alpha}_p(Y^{p,i}_t, \varpi_t), \forall t \in [0, T].
$$

Let us check the market clearing condition under this setup. In order to balance the demand and supply of the securities at the exchange, we need to have $\sum_{p=1}^m \sum_{i=1}^{N_p} \hat{\alpha}(Y^{p,i}_t, \varpi_t) = 0$. This requires the market price to satisfy

$$
\varpi_t = -\left(\sum_{p=1}^m n_p \bar{\Lambda}_p \right)^{-1} \sum_{p=1}^m n_p \bar{\Lambda}_p \left(\frac{1}{N_p} \sum_{i=1}^{N_p} Y^{p,i}_t\right),
$$

where $N = \sum_{p=1}^m N_p$ and $n_p := N_p/N$. At the moment, this is inconsistent to the initial assumption that requires $(\varpi_t)_{t \geq 0}$ to be $\mathbb{F}^0$-adapted. However, since for each $1 \leq p \leq m$, $(Y^{p,i}_t)_{i=1}^{N_p}$ are $\mathbb{F}^0$-conditionally independently and identically distributed, we may follow the same arguments used in Section 3. If we take $N \to \infty$ while keeping the relative size of populations $n_p$ constant, we can expect to obtain

$$
\varpi_t = -\hat{\varpi} \sum_{p=1}^m \hat{\Lambda}_p \mathbb{E}[Y^{p,1}_t | \mathbb{F}^0_t],
$$

(6.3)
in the large population limit where

\[ \hat{\Lambda}_p := n_p \bar{\Lambda}_p, \quad \hat{\Xi} := \left( \sum_{p=1}^{m} \hat{\Lambda}_p \right)^{-1}. \]

**Remark 6.1.** When \( \Lambda_p = \Lambda \) for every population \( p \), one can easily check that (6.3) becomes

\[ \varpi_t = - \sum_{p=1}^{m} n_p \mathbb{E}[Y_{t,1} | \mathcal{F}_t^0]. \]

Since \( Y \) of the adjoint equation represents the marginal cost i.e., the first order derivative of the value function with respect to the state variable \( x \), the above expression of \( \varpi \) implies that the market price may be given by the population-weighted average of the marginal benefit (-cost) across the entire populations.

### 6.1 Limit problem with multiple populations

By the observation we have just made, we are motivated to study the following limit problem with \( 1 \leq p \leq m \):

\[
\begin{align*}
    dX_t^p &= \left( \hat{\alpha}_p(Y_t^p, \varpi(\mathbb{E}[Y_t^p | \mathcal{F}_t^0])) + l_p(t, \varpi(\mathbb{E}[Y_t^p | \mathcal{F}_t^0]), c_t^0, c_t^p) \right) dt \\
    &\quad + \sigma_{p,0}(t, \varpi(\mathbb{E}[Y_t^p | \mathcal{F}_t^0]), c_t^0, c_t^p) dW_t^0 + \sigma_p(t, \varpi(\mathbb{E}[Y_t^p | \mathcal{F}_t^0]), c_t^0, c_t^p) dW_t^{0,1}, \\
    dY_t^p &= -\partial_x \hat{f}_p(t, X_t^p, \varpi(\mathbb{E}[Y_t^p | \mathcal{F}_t^0]), c_t^0, c_t^p) dt + Z_t^{0,0} dW_t^0 + Z_t^{0,1} dW_t^{0,1}, \quad (6.4)
\end{align*}
\]

with \( X_0^p = \xi^p \) and

\[ Y_T^p = -b \varpi(\mathbb{E}[Y_T^p | \mathcal{F}_T^0]) + \partial_x g_p(X_T^p, c_T^0, c_T^p) | \mathcal{F}_T^0 | + \partial_x \hat{g}_p(X_T^p, c_T^0, c_T^p). \]

We put as before \( \xi^p := \xi^{p,1} \) and \( c^p := c^{p,1} \) to lighten the notation. Here,

\[ \varpi(\mathbb{E}[Y_t^p | \mathcal{F}_t^0]) := -\hat{\Xi} \sum_{p=1}^{m} \hat{\Lambda}_p \mathbb{E}[Y_t^p | \mathcal{F}_t^0], \quad \hat{\alpha}_p(y, \varpi) := -\hat{\Lambda}_p(y + \varpi) \]

and hence (6.4) is actually an \( m \)-coupled system of FBSDEs of McKean-Vlasov type. One can derive the terminal condition from

\[ Y_T^p = -b \varpi(\mathbb{E}[Y_T^p | \mathcal{F}_T^0]) + \partial_x \hat{g}_p(X_T^p, c_T^0, c_T^p), \quad (6.5) \]

by summing over \( 1 \leq p \leq m \) after taking conditional expectation given \( \mathcal{F}_T^0 \). In the following, we use the notation

\[ (X_t, Y_t, Z_t^0, Z_t^1)_{t \in [0,T]} = \left( (X_t^p)_{p=1}^m, (Y_t^p)_{p=1}^m, (Z_t^{0,p})_{p=1}^m, (Z_t^{1,p})_{p=1}^m \right)_{t \in [0,T]} \quad (6.6) \]
6.2 Solvability for small $T$

For small $T$, Lipschitz continuity suffices to guarantee the existence of a unique solution.

**Assumption 6.2.** Uniformly in $p \in \{1, \ldots, m\}$, for any $(t, x, c^0, c) \in [0, T] \times (\mathbb{R}^n)^3$ and any \( \omega, \omega' \in \mathbb{R}^n \), the coefficient functions $l_p, \sigma_{p,0}, \sigma_p$ and $\mathcal{F}_p$ satisfy, with $L$ and another nonnegative constant $L_{\omega}$,

\[
|l_p(t, \omega, c^0, c) - l_p(t, \omega', c^0, c)| \leq L |\omega - \omega'|,
\]

\[
|\partial_x \mathcal{F}_p(t, x, \omega, c^0, c) - \partial_x \mathcal{F}_p(t, x, \omega', c^0, c)| \leq L_{\omega} |\omega - \omega'|.
\]

The next theorem follows exactly in the same way as Theorem 4.1.

**Theorem 6.1.** Under Assumptions 6.1 and 6.2, there exists some constant $\tau > 0$ which depends only on $(L, L_{\omega}, b, n_p, \Lambda_p)$ such that for any $T \leq \tau$, there exists a unique strong solution $(X, Y, Z^0, Z) \in S^2(\mathbb{F}; (\mathbb{R}^n)^m) \times S^2(\mathbb{F}; (\mathbb{R}^n)^m) \times H^2(\mathbb{F}; (\mathbb{R}^{n \times d})^m) \times H^2(\mathbb{F}; (\mathbb{R}^{n \times d})^m)$ to the FBSDE (6.1).

**Remark 6.2.** Note that the above system of FBSDEs becomes a linear-quadratic form by choosing $(l_p, \sigma_{p,0}, \sigma_p, \mathcal{F}_p, \mathcal{G}_p)$ appropriately. In this case, the problem reduces to solving ordinary differential equations of Riccati type. Therefore, the existence of a solution for a given $T$ can be tested, at least numerically, by checking the absence of a “blow up” in its solution.

6.3 Solvability for general $T$

We now move on to the existence result of a unique solution for general $T$. It is very difficult to find general existence criteria for fully-coupled multi-dimensional FBSDEs. At the moment, in order to apply well-known Peng-Wu’s method, let us put the following simplifying assumptions.

**Assumption 6.3.**

(i) For every $1 \leq p \leq m$, the functions $\sigma_{p,0}$ and $\sigma_p$ are independent of the argument $\omega$.

(ii) $\Lambda_p = \Lambda$ and $n_p = 1/m$ for every $p$.

(iii) For any $t \in [0, T]$, any random variables $x^p, x^{p'}, c^0, c^p \in L^2(\mathcal{F}; \mathbb{R}^n)$ and any sub-$\sigma$-field $\mathcal{G} \subset \mathcal{F}$, the functions $(l_p)_{p=1}^m$ satisfy the monotone condition, with some positive constant $\gamma > 0$,

\[
\sum_{p=1}^m \mathbb{E}\left[ l_p(t, \mathbb{E}[x^p|\mathcal{G}], c^0, c^0) - l_p(t, \mathbb{E}[x^{p'}|\mathcal{G}], c^0, c^p), x^p - x^{p'} \right] \geq m \gamma \mathbf{1}_{\{L_{\omega} > 0\}} \mathbb{E}\left[ \mathbb{E}[x^p - x^{p'}]|G|^2 \right],
\]

where $\overline{x} := \frac{1}{m} \sum_{p=1}^m x^p$ and similarly for $\overline{x'}$.

(iv) There exists a strictly positive constant $\gamma$ satisfying $0 < \gamma \leq \left( \gamma^f - \frac{L_{\omega}}{4\gamma} \right) \wedge \gamma^q$. Moreover, the functions $(\mathcal{G}_p)_{p=1}^m$ satisfy for any $x^p, x^{p'}, c^0, c^p \in L^2(\mathcal{F}; \mathbb{R}^n)$ and any sub-$\sigma$-field $\mathcal{G} \subset \mathcal{F}$,

\[
\mathbb{E}\left[ \sum_{p=1}^m \mathbb{E}\left[ \partial_x \mathcal{G}_p(x^p, c^0, c^p) - \partial_x \mathcal{G}_p(x^{p'}, c^0, c^p)|\mathcal{G}^p, \sum_{p=1}^m (x^p - x^{p'}) \right] \right] + \gamma \mathbb{E}\left[ \mathbb{E}[x^p - x^{p'}]|G|^2 \right] \geq \gamma \sum_{p=1}^m \mathbb{E}[|x^p - x^{p'}|].
\]

23
Remark 6.3. The conditions (iii) and (iv) in the above assumption are rather restrictive. The condition (iii) is satisfied, for example, if $l_p$ has a separable form $l_p = h(x) + h_p(c_1^p, c_2^p)$ with some function $h$, which is common to every population and strictly monotone. (iv) is also satisfied by requiring similar structure. Or, since $\partial_x g_p$ is Lipschitz continuous in $x$, the absolute value of the first term is bounded by $\frac{b}{1-b} \max((L_p_{m=1}) \sum_{m=1}^m E|x^m - x^{m'}|^2$, where the $L_p$ is the Lipschitz constant for $\partial_x g_p$. Thus the condition (iv) is satisfied if $b \max((L_p_{m=1})$ is sufficiently small.

The next result is the counterpart of Theorem 4.2.

Theorem 6.2. Under Assumptions 6.1, 6.2, 6.3 there exists a unique strong solution $(X,Y,Z^0,Z)$ to $S^2(F;\mathbb{R}^m) \times S^2(F;\mathbb{R}^m) \times \mathbb{H}^2(F;\mathbb{R}^n \times \mathbb{H}^2(F;\mathbb{R}^n \times \mathbb{H}^2(F;\mathbb{R}^n \times \mathbb{H}^2(F;\mathbb{R}^n)$ with the FBSDE (6.4). Moreover, the same form of stability and $L^2$ estimates given in Proposition 4.1 and Corollary 4.3 hold.

Proof. Under Assumption 6.3, (6.4) can be written as

$$dX_t^p = \{-\mathbb{A}(Y_t^p - \frac{1}{m} \sum_{m=1}^m E[Y_t^p | \mathcal{F}_t^0]) + l_p(t, -\frac{1}{m} \sum_{m=1}^m E[Y_t^p | \mathcal{F}_t^0], c_1^0, c_2^0)\} dt$$

$$+ \sigma_p(t, c_1^0, c_2^0) dW_t^0 + \sigma_p(t, c_1^0, c_2^0) dW_t^{p,1},$$

$$dY_t^p = -\partial_x \mathbb{A} p(t, X_t^p, -\frac{1}{m} \sum_{m=1}^m E[Y_t^p | \mathcal{F}_t^0], c_1^0, c_2^0) dt + Z_t^0 dW_t^0 + Z_t^1 dW_t^{p,1},$$

with $X_0^p = \xi^p$ and

$$Y_t^p = \frac{b}{1-b} \frac{1}{m} \sum_{m=1}^m E[\partial_x g_p(X_t^p, c_1^0, c_2^0) | \mathcal{F}_t^0] + \partial_x \mathbb{A} p(X_t^p, c_1^0, c_2^0).$$

For each $p$, let us define the functionals $B_p, F_p$ and $G_p$ for any $y^p, x^p, c_0, c^p \in L^2(\mathcal{F};\mathbb{R}^n)$ with $y := (y^p)_{p=1}^m, x := (x^p)_{p=1}^m$ and $c := (c^p)_{p=1}^m$ by

$$B_p(t, y, c_0, c^p) := -\mathbb{A}(y^p - \frac{1}{m} \sum_{m=1}^m E[y^p | \mathcal{F}_t^0]) + l_p(t, -\frac{1}{m} \sum_{m=1}^m E[y^p | \mathcal{F}_t^0], c_0, c^p)$$

$$F_p(t, x^p, y, c_0, c^p) := -\partial_x \mathbb{A} p(t, x^p, -\frac{1}{m} \sum_{m=1}^m E[y^p | \mathcal{F}_t^0], c_0, c^p),$$

$$G_p(x, c_0, c) := \frac{b}{1-b} \frac{1}{m} \sum_{m=1}^m E[\partial_x \mathbb{A} p(x^p, c_0, c^p) | \mathcal{F}_t^0] + \partial_x \mathbb{A} p(x^p, c_0, c^p),$$

and set $B(t, y, c_0, c) := (B_p(t, y, c_0, c^p))_{p=1}^m, F(t, x, y, c_0, c) := (F_p(t, x^p, y, c_0, c^p))_{p=1}^m$ and $G(x, c_0, c) :=$...
\((G_p(x, c^0, c))_{p=1}^m\). With \(\Delta y := y - y'\) and \(\Delta x := x - x'\), we have from Assumption 6.3 (iii),

\[
\mathbb{E}\left[\langle B(t, y, c^0, c) - B(t, y', c^0, c), \Delta y \rangle\right] := \sum_{p=1}^m \mathbb{E}\left[\langle B_p(t, y, c^0, c) - B_p(t, y', c^0, c), \Delta y^p \rangle\right]
\]

\[
\leq -\sum_{p=1}^m \mathbb{E}\left[\langle \Delta y^p, L \Delta y^p \rangle\right] + \frac{1}{m} \mathbb{E}\left[\left(\sum_{p=1}^m \mathbb{E}[\Delta y^p | F_t], \sum_{p=1}^m \Delta y^p\right) - m \gamma^l 1_{\{L > 0\}} E\left[\left(\frac{1}{m} \sum_{p=1}^m \mathbb{E}[\Delta y^p | F_t]\right)^2\right]\right]
\]

\[
\leq -m \gamma^l 1_{\{L > 0\}} E\left[\left(\frac{1}{m} \sum_{p=1}^m \mathbb{E}[\Delta y^p | F_t]\right)^2\right]. \tag{6.7}
\]

There exists a orthogonal matrix \(P\) such that \(P^T L P\) becomes diagonal. Then working on the new basis \(\tilde{y}^p = P^T \Delta y^p\), 1 \(\leq p \leq m\), the last inequality of (6.7) can be checked component by component 1 \(\leq i \leq n\) by the fact \((\sum_{p=1}^m \tilde{y}^p_i)^2 \leq m \sum_{p=1}^m |\tilde{y}^p_i|^2\). Second, from Assumptions 6.1(iv), 6.2 and Cauchy-Schwarz inequality,

\[
\mathbb{E}\left[\langle F(t, x, y, c^0, c) - F(t, x', y', c^0, c), \Delta x \rangle\right] := \sum_{p=1}^m \mathbb{E}\left[\langle F_p(t, x, y, c^0, c) - F_p(t, x', y', c^0, c), \Delta x^p \rangle\right]
\]

\[
\leq -\left(\gamma^f - \frac{L^2}{4 \gamma^l}\right) \mathbb{E}[||\Delta x||^2] + m \gamma^l 1_{\{L > 0\}} E\left[\left(\frac{1}{m} \sum_{p=1}^m \mathbb{E}[\Delta y^p | F_t]\right)^2\right]. \tag{6.8}
\]

Finally, from Assumptions 6.1 and 6.3(iv), we immediately get

\[
\mathbb{E}\left[\langle G(x, c^0, c) - G(x', c^0, c), \Delta x \rangle\right] := \sum_{p=1}^m \mathbb{E}\left[\langle G_p(x, c^0, c) - G_p(x', c^0, c), \Delta x^p \rangle\right] \geq \gamma \mathbb{E}[||\Delta x||^2] .
\]

Now we have established the monotone conditions corresponding to (4.3) for the current model. We can now repeat the same procedures in the proof of Theorem 4.2 and Proposition 4.1. \(\square\)

Let us give the results for the securities of maturity \(T\) with exogenously specified payoff.

**Assumption 6.4.**

The same conditions as in Assumption 6.3 except (iv), which is replaced by

(iv)' \(\gamma := \gamma^f - \frac{L^2}{4 \gamma^l}\) is strictly positive. Moreover, \(b = 0\) and the terminal function \(g_p\) is given by

\[
g_p(x, c^0) = \varpi_p(x, c^0) := -\langle c^0, x \rangle \tag{6.9}
\]

for every 1 \(\leq p \leq m\).

**Proposition 6.1.** Under Assumptions 6.1, 6.2 and 6.4, there exists a unique strong solution \((X, Y, Z, 0, Z) \in S^2\left(F^1; (\mathbb{R}^n)^m\right) \times S^2\left(F^1; (\mathbb{R}^n)^m\right) \times H^2\left(F^1; (\mathbb{R}^{n \times d})^m\right) \times H^2\left(F^1; (\mathbb{R}^{n \times d})^m\right)\) to the FBSDE (6.4). Moreover, the same form of the stability and \(L^2\) estimates given in Proposition 4.7 and Corollary 4.7 holds.

**Proof.** Using the inequalities (6.7) and (6.8) with \(\sum_{p=1}^m \langle \Delta X^p_T, \Delta Y^p_T \rangle = 0\), we can follow the same arguments in the proof of Proposition 4.2. \(\square\)
6.4 Asymptotic market clearing for multi-population model

At the last part of this section, we investigate the asymptotic market clearing in the presence of multiple populations. As in Section 5, we define \( (\varpi_t)_{t \in [0,T]} \) using the solution to the system of the mean-field FBSDEs:

\[
\varpi_t = \varpi(\mathbb{E}[Y_t|\mathcal{F}^0_t]) := -\hat{\varepsilon} \sum_{p=1}^{m} \hat{\Lambda}_p \mathbb{E}[Y^p_t|\mathcal{F}^0_t]
\]

where \( (Y^p_t)_{p=1}^{m} \) is the solution of (6.4). In order to test the accuracy of the above \( (\varpi_t)_{t \in [0,T]} \) as a market clearing price, we solve the individual agent problem (6.1) with this \( \varpi \) as an input. The corresponding individual problem (6.1) for the agent \((p,i)\) is given by the unique strong solution \((X^{p,i}, Y^{p,i}, Z^{p,i,0}, Z^{p,i})\) of (6.2). The optimal strategy for the agent \((p,i)\) is then given by

\[
\tilde{\alpha}_{\text{mf}}^{p,i}(t) := -\hat{\Lambda}_p \left( Y^{p,i}_t - \hat{\varepsilon} \sum_{q=1}^{m} \hat{\Lambda}_q \mathbb{E}[Y^q_t|\mathcal{F}^0_t] \right), \forall t \in [0,T].
\]

**Theorem 6.3.** If the conditions for Theorem 6.1, Theorem 6.2 or Proposition 6.1 are satisfied then we have

\[
\lim_{N \to \infty} \mathbb{E} \int_0^T \left| \frac{1}{N} \sum_{p=1}^{m} \sum_{i=1}^{N_p} \tilde{\alpha}_{\text{mf}}^{p,i}(t) \right|^2 dt = 0,
\]

where \(N := \sum_{p=1}^{m} N_p\) and the limit is taken while keeping \((n_p := N_p/N)_{1 \leq p \leq m}\) constant. Moreover if there exists some constant \(\Gamma\) such that \(\sup_{t \in [0,T]} \mathbb{E}[|Y_t|^q]^{\frac{1}{q}} \leq \Gamma < \infty\) for some \(q > 4\), then there exists some constant \(C\) independent of \(N\) such that

\[
\mathbb{E} \int_0^T \left| \frac{1}{N} \sum_{p=1}^{m} \sum_{i=1}^{N_p} \tilde{\alpha}_{\text{mf}}^{p,i}(t) \right|^2 dt \leq C \Gamma^2 \epsilon_N,
\]

where \(\epsilon_N := N^{-2/\max(n,4)} (1 + \log(N)1_{\{n=4\}})\).

**Proof.** By the definition of \(\tilde{\alpha}_{\text{mf}}^{p,i}\), we have

\[
\frac{1}{N} \sum_{p=1}^{m} \sum_{i=1}^{N_p} \tilde{\alpha}_{\text{mf}}^{p,i}(t) = -\frac{1}{N} \sum_{p=1}^{m} \sum_{i=1}^{N_p} \hat{\Lambda}_p \left( Y^{p,i}_t - \hat{\varepsilon} \sum_{q=1}^{m} \hat{\Lambda}_q \mathbb{E}[Y^q_t|\mathcal{F}^0_t] \right)
\]

\[
= -\sum_{p=1}^{m} \hat{\Lambda}_p \left( \frac{1}{N_p} \sum_{i=1}^{N_p} Y^{p,i}_t - \mathbb{E}[Y^p_t|\mathcal{F}^0_t] \right).
\]

On the other hand, we have for each 1 \(\leq p \leq m, 1 \leq i \leq N_p\),

\[
dX^{p,i}_t = \left( \tilde{\alpha}_p (Y^{p,i}_t, \varpi(\mathbb{E}[Y_t|\mathcal{F}^0_t])) + l_p (t, \varpi(\mathbb{E}[Y_t|\mathcal{F}^0_t]), c^0_t, c^{p,i}_t) \right) dt
\]

\[
+ \sigma_{p,0} (t, \varpi(\mathbb{E}[Y_t|\mathcal{F}^0_t]), c^0_t, c^{p,i}_t) dW^0_t + \sigma_p (t, \varpi(\mathbb{E}[Y_t|\mathcal{F}^0_t]), c^0_t, c^{p,i}_t) dW^{p,i}_t,
\]

\[
dY^{p,i}_t = -\partial_2 \tilde{\alpha}_p (t, X^{p,i}_t, \varpi(\mathbb{E}[Y_t|\mathcal{F}^0_t]), c^0_t, c^{p,i}_t) dt + Z^{p,i,0}_t dW^0_t + Z^{p,i}_t dW^{p,i}_t,
\]

26
with $X_0^{p,i} = \xi^{p,i}$,
\[ Y_t^{p,i} = -b(\mathbb{E}[Y_T^p | \mathcal{F}_t]) + \partial_x g_p(X_t^{p,i}, c_t^0, c_t^{p,i}). \]

By the unique strong solvability, Yamada-Watanabe theorem implies that there exists some function $\Phi_p$ for each $1 \leq p \leq m$ such that for every $1 \leq i \leq N_p$,
\[ (Y_t^{p,i})_{t \in [0,T]} = \Phi_p\left(c_0^0, (W_t^0)_{t \in [0,T]}, (\mathbb{E}[Y_T^p | \mathcal{F}_t])_{t \in [0,T]} \right) \]

Hence $(Y_t^{p,i})_{t \in [0,T], 1 \leq i \leq N_p}$ are independently and identically distributed conditionally on $\mathcal{F}^0_t$. In particular, we have $\mathbb{E}[Y_t^{p,i} | \mathcal{F}_t] = \mathbb{E}[Y_t^{p,i} | \mathcal{F}_t]$. We now compare $(X_t^{p,1}, Y_t^{p,1}, Z_t^{p,1,0}, Z_t^{p,1})_{t \in [0,T]}$ with $(X_t^0, Y_t^0, Z_t^0, Z_t^0)_{t \in [0,T]}$ by treating $\varpi(\mathbb{E}[Y_t^0 | \mathcal{F}_t])$ as external inputs. Note that the terminal condition of the latter satisfies the relation (6.5). Then the standard stability result of the Lipschitz FBSDEs implies $(Y_t^{p,1})_{t \in [0,T]} = (Y_t^0)_{t \in [0,T]}$ in $\mathbb{S}^2(\mathbb{F}^{p,1}; \mathbb{R})$. As a result we have obtained $\mathbb{E}[Y_t^{p,i} | \mathcal{F}_t] = \mathbb{E}[Y_t^{p,1} | \mathcal{F}_t]$. Using the expression (6.10), we obtain
\[ \frac{1}{N} \sum_{p=1}^{m} \sum_{i=1}^{N_p} \hat{\alpha}^{p,i}(t) = - \frac{1}{N_p} \sum_{i=1}^{N_p} Y_t^{p,i} - \mathbb{E}[Y_t^{p,1} | \mathcal{F}_t]. \]

We can now repeat the last part of the proof for Theorem 5.1.\hfill \Box

7 Extensions and Concluding Remarks

In this work, we have studied endogenous formation of market clearing price using a stylized model of the securities exchange. We have derived a special type of FBSDE of McKean-Vlasov type with common noise whose solution provides an approximate of the equilibrium price. In addition to the existence of strong unique solution to the FBSDE, we have proved that the modeled price asymptotically clear the market in the large $N$-limit. We also gave the order of convergence $\epsilon_N$ when the solution of the FBSDE possesses higher order of integrability. In the following, let us list up of a further extension of our technique and some interesting topics for future projects:

- Dependence on the conditional law of the state: For applications to energy and commodity markets, or economic models with producers and consumers, one may want to study the cost functions $(\mathcal{F}, \mathcal{G})$ depending on the empirical distribution of the state $X$ of the agents such as $\mathcal{F}(t, X_t, \frac{1}{N} \sum_{j=1}^{N} \delta_{X_j^t}, \varpi_t, c_t^0, c_t^i)$. Under the setup with conditional independence, the cost function for the limit problem is naturally given by $\mathcal{F}(t, X_t, \mathcal{L}(X_t | \mathcal{F}_t), \varpi_t, c_t^0, c_t^i)$. Even in this case, the resultant FBSDE (11.1) is solvable, at least for small $T$, if $(\partial_x \mathcal{F}, \partial_x \mathcal{G})$ are Lipschitz continuous in the measure argument with respect to $W_2$-distance. Under the stronger assumption guaranteeing the monotone conditions (1.3), one can even achieve the existence of unique solution in general $T$. As long as the common noise is solely from the filtration $\mathcal{F}_t^0$ generated by $W^0$, we can avoid subtleties regarding the admissibility (so-called $H$-hypothesis). See [14, Remark 2.10] as a useful summary for this issue.
• **Explicit solution**: If we chose $\mathcal{F}$ as quadratic functions and $l, \sigma_0, \sigma$ as affine functions, we obtain a linear-quadratic mean field game with common noise. In this case, an explicit solution may be available where the coefficients functions are given as the solutions to differential equations of Riccati type.

• **Property of market price process**: It seems interesting to study the properties of the market clearing price theoretically and numerically. For example, if $n = d^0$ the equivalent martingale measure (EMM) can be uniquely determined. Based on the payoff distribution $c^0$ and the cost functions of the agents $(\mathcal{F}, \mathcal{G})$, one may study how the market price process under the EMM behaves, for example, the relation between the skew of its implied volatility and the risk-averseness of the agents.

• **Market clearing equilibrium with a major agent**: The problem of equilibrium price formation in the presence of a major agent is an important problem. In our recent work Fujii & Takahashi (2021) [23], we provide the extension of the current model in the presence of a major financial firm who has a non-negligible market share even in the large-population limit of the minor financial firms.
