The Two-Dimensional Liquid Crystal Droplet Problem with a Tangential Boundary Condition

ZHIYUAN GENG & FANGHUA LIN

Communicated by E. VIRGA

Abstract

This paper studies a shape optimization problem which reduces to a nonlocal free boundary problem involving perimeter. It is motivated by a study of liquid crystal droplets with a tangential anchoring boundary condition and a volume constraint. We establish in 2D the existence of an optimal shape that has two cusps on the boundary. We also prove that the boundary of the droplet is a chord–arc curve with its normal vector field in the VMO space, and its arc-length parameterization belongs to the Sobolev space $H^{3/2}$. In fact, the boundary curves of such droplets closely resemble the so-called Weil–Petersson class of planar curves. In addition, the asymptotic behavior of the optimal shape when the volume becomes extremely large or small is studied.

1. Introduction

1.1. Background

Liquid crystal droplets are of great interest in terms of both theory and applications. They are important in studies of topological defects in the bulk or on the surface of liquid crystals, and they are useful in the understanding of anisotropic surface energies and variety anchoring conditions. Determining the shape of the droplets and the associated equilibrium configurations of the liquid crystals leads to a shape optimization problem that, in some cases, becomes a nonlocal free boundary problem.

The authors are partially supported by the NSF Grant DMS1955249. The first author is partially supported by the Basque Government through the BERC 2018-2021 program and by the Spanish State Research Agency through BCAM Severo Ochoa excellence accreditation SEV-2017-0718 and through project PID2020-114189RB-I00 funded by Agencia Estatal de Investigación (PID2020-114189RB-I00/AEI/10.13039/501100011033).
We are particularly interested in the elongated droplets known as tactoids, which usually possess a characteristic eye shape. After a quick examination, one finds the boundary anchoring condition for the molecular orientation to achieve such a desired shape needs to be a tangential anchoring, that is, the director is orthogonal to the normal of the droplet boundary.

Mathematically, the most commonly used continuum theory to describe nematic liquid crystals is the Oseen–Frank theory, proposed by Oseen [35] in 1933 and Frank [15] in 1958. In the Oseen–Frank theory, the local state of the liquid crystal is described by a $\mathbb{S}^1$- or $\mathbb{S}^2$-valued vector $n$ that represents the mean local orientation of molecule’s optical axis. Let $\Omega$ be the region occupied by a nematic liquid crystal droplet, the Oseen–Frank bulk energy associated with the director field is the functional

$$E_{OF}(n, \Omega) = \int_{\Omega} w(n, \nabla n) \, dx,$$

where

$$w(n, \nabla n) = k_1 (\text{div} \, n)^2 + k_2 (n \cdot \text{curl} \, n)^2 + k_3 |n \times \text{curl} \, n|^2$$

$$+ (k_2 + k_4) \left( \text{tr}(\nabla n)^2 - (\text{div} \, n)^2 \right).$$

We shall consider the one-constant approximation, that is, $k_1 = k_2 = k_3 = 1$ and $k_4 = 0$, where the energy functional (1.1) reduces to

$$E_{OF}(n, \Omega) = \int_{\Omega} |\nabla n|^2 \, dx,$$

which is the energy functional for harmonic maps. Harmonic maps have been extensively studied in the past several decades, which are much better understood. Interested readers can refer to [30] and the references therein.

Liquid crystal droplets are often either dispersed in a polymeric medium or surrounded by another fluid such as water. There is an interfacial energy which will play an essential role in determining the optimal shapes. Following [16] and [35], the surface energy may be written as

$$E_s(\Omega, n) = \int_{\partial \Omega} f(n \cdot \nu) \, dA,$$

where $\nu$ is the outer normal on $\partial \Omega$ and for simplicity, $f$ is assumed to have the form (see [10])

$$f(\rho) = \mu (1 + \lambda \rho^2)$$

for some $\mu > 0$ and $-1 < \lambda < \infty$. Thus, the total energy for a liquid crystal droplet configuration is given by

$$E(\Omega, n) = E_{OF}(\Omega, n) + E_s(\Omega, n).$$

As both the shape of $\Omega$ and the director $n$ are varying, determining the stable configuration leads to the following free boundary problem:
Problem 1.1. Find a pair \((\Omega, n)\), that minimizes the functional

\[
E(\Omega, n) = \int_{\Omega} w(n, \nabla n) \, dx + \int_{\partial\Omega} f(n \cdot \nu) \, dA,
\]

subject to the constraint \(\text{vol}(\Omega) = V\).

Here \(\text{vol}\) denotes Lebesgue measure and \(V\) is a positive constant.

Problem 1.1 has drawn great attention from both physicists and mathematicians. There are many research works on Problem 1.1 with physical experiments, numerical simulations and formal analysis, see, for example, \([9, 26, 27, 32, 34, 36, 37, 39, 42]\). On the other hand, rigorous theoretical treatment of this problem is more challenging because of the difficulty of determining the shape and the director at the same time. One way to overcome such a difficulty is to assume the droplets have a simple geometry, such as a disk, an ellipse or a intersection region of two disks, see, for example, \([24, 42, 44]\). In these works, the shape of the droplet is either fixed or determined by only one or two parameters (such as the eccentricity of an ellipse). The minimization often involves finding the best shape parameter and the director field under various boundary conditions and different Oseen–Frank elastic constants. Another way is to presume the configuration of the director field (such as a constant vector field) and then find the best shape that minimizes the surface energy alone, subject to the fixed volume constraint, see, for example, \([39, 43]\). These two methods are useful to partially justify the phenomena observed in experiments but are not satisfactory from a mathematical point of view.

A more rigorous study of Problem 1.1 was conducted by the second author and Poon in \([29]\). Under the key assumption that all admissible domains are convex, they establish the existence and partial regularity of Problem 1.1 (see \([29, \text{Theorem 2.4}]\)). The convexity assumption on the shape of droplets, on one hand, makes the problem more accessible mathematically, and on the other hand, it does match many experimental observed liquid crystals droplets which are of shapes of ellipsoids (balls) and cigars. In this connection, they also studied the cases when the surface energy favors the normal boundary anchoring condition or the tangential boundary anchoring condition. When \(\lambda > 0\) and \(\mu\) is very large, for any minimizing pair \(\{\Omega, n\}\) of Problem 1.1, \(n \cdot \nu\) has to be close to zero almost everywhere on \(\partial\Omega\). This leads to the so-called tangential anchoring boundary condition: \(n \cdot \nu = 0\) on \(\partial\Omega\). Problem 1.1 is then reformulated as follows:

Problem 1.2. (Problem B in \([29]\)) Find a pair \((\Omega, n)\) that minimizes

\[
\int_{\Omega} w(n, \nabla n) \, dx + \mu \text{Area}(\partial\Omega)
\]

such that (i) \(\text{vol}(\Omega) = V\) and (ii) \(n \cdot \nu = 0\) on \(\partial\Omega\).

When \(-1 < \lambda < 0\) and \(\mu\) is very large, \(n \cdot \nu\) needs to be close to 1 on \(\partial\Omega\). In this case, one gets the normal anchoring boundary condition: \(n \cdot \nu = 1\) on \(\partial\Omega\), which leads to the following problem:
Problem 1.3. (Problem C in [29]) Find a pair \((\Omega, n)\) that minimizes
\[
\int_{\Omega} w(n, \nabla n) \, dx + \mu \text{Area}(\partial \Omega)
\]
such that (i) \(\text{vol}(\Omega) = V\) and (ii) \(n \cdot \nu = 1\) on \(\partial \Omega\).

It is proved in [29] that there are minimizers among convex domains \(\Omega\) for both Problem 1.2 and Problem 1.3. Moreover, the only solution to Problem 1.3 (up to a Euclidean motion) is \((B_R, \frac{x}{|x|})\), such that \(|B_R| = V\).

Li and Wang recently extend the previous result in which they replace the convexity assumption by a notion of M-uniform domains, see [28]. It is worth noting that Problems 1.1, 1.2 and 1.3 thus presented were all derived from a phenomenological theory, see [35] and [10]. In a recent work [31], it is shown that one can rigorously establish these model problems from a general theory of Ericksen (for liquid crystals with variable degree of orientations [11]) or from the de Gennes–Landau model of liquid crystals [13] in suitable physical regimes.

From our experience, one can likely establish a general existence and partial regularity theory for Problems 1.1, 1.2 and 1.3 without the convexity assumption on the shape of \(\Omega\). However, one also expects such a theory will not be able to tell certain particular shapes and configurations (that are observed in experiments and numerical simulations) are minimizers and it is usually difficult to construct solutions for the Euler–Lagrange equation. In particular, one likely will not be able to deduce that tactoid-, ball-, cigar- and apple-shaped droplets are minimizers. The latter are in fact commonly observed in experiments and of interest to many researchers.

In this article, we will concentrate on the two-dimensional case of Problem 1.2, where the tangential anchoring boundary condition and the fixed volume constraint are presumed. The minimizer is expected to have a spindle shape, which is known as tactoids, and a bipolar director field. Here the bipolar director field refers to an axially symmetric configuration with tangential anchoring boundary condition, such that two boojums are located at opposite ends of the axis. If one investigates thin liquid crystal samples in experiments, the region of nematic liquid crystals will form a planar domain (tactoid) whose boundary consists of two curves that meet at two singular points and form angles or cusps. For more experimental evidence and numerical simulations of tactoids with such bipolar director configurations, readers are referred to [9,26,36–39,42] for more details. These works also manifest the significance of tactoids as an object of study.

There are several works that focus on the rigorous mathematical analysis of tactoids with tangential anchoring of the director on the surface. Shen et al. [40] discussed such bipolar configurations of droplet in the fixed spherical domain case as well as the free boundary case. For the latter, they introduce a relaxed energy to establish the existence of critical points and some stability results. Recently, a model problem based on highly disparate elastic constants is proposed by Golovaty, Novack, Sternberg and Venkatraman in [20] to understand corners and cusps that form on the nematic–isotropic interface. They prove some \(\Gamma\)-convergence results (when some elastic constant \(\epsilon\) goes to 0) and study the role played by the boundary
tangency requirement and the elastic anisotropy on the formation of interfacial singularities.

In this work, we investigate the planar tactoids by solving Problem 1.2. What distinguishes our work from the previous work of Lin and Poon is that we drop the convexity assumption on the domain $\Omega$. Instead, we only assume a symmetry assumption with respect to the $x$-axis as well as some basic technical assumptions (see conditions (i)–(v) in Section 1.2) for the boundary of the droplet. Note that in most of experiments, it is observed that liquid crystal droplets possess the axial symmetry. We first prove some geometric properties of the free boundary. The main property is that away from two cusps, the boundary curve $\Gamma$ is a vanishing chord–arc curve and the boundary normal vector $\nu$ is in VMO. Furthermore, we notice that our curve $\Gamma$ has many similar properties with the so-called Weil–Petersson curve (see Section 2.3). As a consequence, the arc-length parameterization of the curve is in the Sobolev space $H^{3/2}$. Then using these properties, we demonstrate the existence of a global minimizer with two cusps on the boundary, which verifies the shape of tactoids. In fact, we show that two cusps must appear at the intersection points of the interface and the $x$-axis for all global minimizers. Moreover, an Euler–Lagrange equation is also derived under extra regularity assumptions on $\Gamma$. Finally, we study the asymptotic shape of the nematic drop when the volume tends to be very large or very small. Note that due to the very strong nonlocal character of this problem, currently we are not able to show that $\nu$ is continuous on the boundary. We hope to prove higher regularity results in the future.

1.2. Mathematical formulation

Now we give the precise formulation of the model problem. Note that what we have in mind is the tactoid that forms two cusps on the boundary. Set $\Omega \subset \mathbb{R}^2$ as the simply connected region which is a domain enclosed by a Jordan curve with finite length. We denote by $n \in S^1$ the unit vector that represents the director of liquid crystal. The Oseen–Frank bulk energy is given by (1.3). Then the variational problem is

**Problem 1.4. (2D case of Problem 1.2)** Find a pair $\{\Omega, n\}$ that minimizes

$$
\int_\Omega |\nabla n|^2 \, dx + \text{Per}(\partial \Omega)
$$

such that $\text{vol}(\Omega) = V$ and $n \cdot \nu = 0$ on $\partial \Omega$. Here Per means the perimeter.

Here we want to point out that this formulation already implies that the boundary of the minimizer $\Omega$ cannot be smooth everywhere. We can explain it in this way: If $\partial \Omega$ is a closed smooth curve and the boundary tangential vector is continuous, then the topological degree of tangential vector is at least one, and therefore, there is no finite Dirichlet energy extension of $n|_{\partial \Omega}$ inside the 2D domain $\Omega$ (see [4, p. xiii]).

Now we refine this problem by adding more constraints and then introduce the final version of the problem that we will study.

First we assume $\Omega$ is symmetric with respect to $x$-axis. And therefore we only consider half of the domain located in the upper half plane. Let $\Gamma$ be a rectifiable curve that satisfies following conditions:
(i) $\Gamma = \{(x(t), y(t)) : x, y \in AC([0, l(\Gamma)]), where l(\Gamma)$ is the length of $\Gamma$. 

(ii) $(x(0), y(0)) = (-a, 0)$, $(x(1), y(1)) = (a, 0)$ for some $a > 0$. 

(iii) $\mathcal{H}^1(\Gamma \cap \{(x, 0) : x \in \mathbb{R}) = 0.$

(iv) $x'(t) \geq 0$, $y'(t) \geq 0$, $(x(t), y(t)) \neq (x(s), y(s))$ for $s \neq t$.

(v) $\sqrt{|x'|^2 + |y'|^2} = 1$ almost everywhere.

Note that here condition (i) and (v) mean that we parameterize $\Gamma$ by unit length; condition (ii) implies two endpoints of $\Gamma$ belong to $x$-axis; condition (iv) tells that $\Gamma$ does not touch itself and will always “go from left to right.” Now we define $\Omega_{\Gamma}$ as the region enclosed by $\Gamma$ and $x$-axis. Note that so far $\Omega_{\Gamma}$ might not be a simply connected region since $\Gamma(t)$ may touch $x$-axis at some other point between two endpoints. However, we will show later, in Lemma 2.1, that for a minimizer, $\Omega_{\Gamma}$ has to be simply connected.

The boundary condition for director $n$ on $\partial \Omega_{\Gamma} = \{(x, 0) : x \in [-a, a]\} \cap \Gamma$ is given by

$$n(x, y) = (1, 0) \text{ on } \{(x, 0) : x \in [-a, a]\},$$

$$n(x(t), y(t)) = (x'(t), y'(t)) \text{ on } (x(t), y(t)) \in \Gamma.$$ 

Here the condition $n(x, y) = (1, 0)$ on $\{(x, 0) : x \in [-a, a]\}$ is due to the axial symmetry assumption with respect to the $x$-axis.

Note that in 2D, for $n \in H^1(\Omega_{\Gamma}, S^1)$, we can write it as $(n_1, n_2) = (\cos \Theta, \sin \Theta)$ for some $\Theta \in H^1(\Omega_{\Gamma}, \mathbb{R})$ (see [6, Theorem 1] for the existence of such lifting). Then by the chain rule we have that

$$|\nabla n|^2 = \sin^2 \Theta |\nabla \Theta|^2 + \cos^2 \Theta |\nabla \Theta|^2 = |\nabla \Theta|^2.$$ 

We will work with this angle function $\Theta$. Then the corresponding boundary condition for $\Theta$ is

$$\Theta(x, y) = 0 \text{ on } \{(x, 0) : x \in [-a, a]\}$$

$$\Theta(x(t), y(t)) = \arcsin y'(t) \text{ on } (x(t), y(t)) \in \Gamma.$$  

(1.7)

Here arcsin is defined on $[-1, 1]$ and maps to $[-\pi/2, \pi/2]$. Now we are ready to define the following admissible set for $\Gamma$:

$$\mathcal{G}_V := \{\Gamma \text{ satisfies condition (i–v), and } \Theta|_{\partial \Omega_{\Gamma}} \text{ has a harmonic extension } \Theta \text{ defined in } \overline{\Omega_{\Gamma}} \text{ such that } \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy < \infty \text{ and } |\Omega_{\Gamma}| = V\}.$$ 

Here $V$ is a positive constant representing the volume of $\Omega_{\Gamma}$. Figure 1 shows our assumptions on $\Gamma$, $\Omega_{\Gamma}$ and the tangential anchoring condition for $\Theta$.

To this end, we consider the following variational problem

**Problem 1.5. (Final Problem)** Find $\Gamma \in \mathcal{G}_V$ that minimizes the functional 

$$E(\Gamma) = \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy + l(\Gamma),$$ 

(1.8)
where $\Theta$ is determined by $\Gamma$ in the following way:

$$\begin{cases}
\Delta \Theta = 0, & \text{in } \Omega^\Gamma, \\
\Theta \mid_{\partial \Omega^\Gamma} & \text{is defined as in (1.7).}
\end{cases}$$

We will study the existence and properties of global energy minimizers of Problem 1.5 in the rest of the article. In Section 2, we prove various geometric properties of $\Gamma$ and $\Omega^\Gamma$. When the energy $E(\Gamma)$ is finite (not necessarily a minimizer), we show that $\Gamma$ is a vanishing chord–arc curve and $v \in \text{VMO}$ on $\Gamma$. Moreover, the arc-length parameterization belongs to $H^{3/2}(0, l)$. As a consequence, the function $\Theta$ defined on $\Omega^\Gamma$ can be extended to a $H^1$ function on $\mathbb{R}^2$ according to the classical theory on the relationship of quasidisks and Sobolev extension domains. The existence of a global minimizer for Problem 1.5 is established in Section 3. The proof relies heavily on the properties proved in Section 2. We also show that for all the global minimizers, $\Gamma$ and $x$-axis will form two cusps near two intersection points. Under the assumption that $\Gamma$ can be written as the graph of a sufficiently regular function $f$, the Euler–Lagrange equation for $\Gamma$ is also derived. Finally in Section 4 we study asymptotic profiles of $\Gamma$ when the volume $V$ tends to be very large or small.

We would like to point out that this article just represents an initial investigation of Problem 1.5, and there are many open problems to be studied in the future.

### 2. Geometric Properties of $\Gamma$ and $\Omega^\Gamma$

#### 2.1. Sobolev extension domain

We assume $V = 1$ throughout this section. And if there exists an energy minimizer for Problem 1.5, we denote it by $\Gamma_m$. We further write the corresponding $\Omega_{\Gamma_m}$ and $\Theta$ function as $\Omega_m$ and $\Theta_m$. We start with the observation that

**Claim.** $\mathcal{G}_1$ is not empty. There is at least one smooth curve $\Gamma \in \mathcal{G}_1$.

Actually we can find a smooth curve $\Gamma_0 \in \mathcal{G}_1$ by directly constructing a curve $\Gamma_0$. Let $\Gamma_0$ be the graph of function $f_0(x) = \frac{\cos x + 1}{2\pi}$, $x \in [-\pi, \pi]$. By definition, $\Omega_{f_0} = \{(x, y) : -\pi \leq x \leq \pi, 0 \leq y \leq f_0(x)\}$ and we set $\Theta_0(x, y) = -\frac{2\pi y}{\cos x + 1} \arctan \frac{\sin x}{2\pi}$ for $(x, y) \in \Omega_{f_0}$. It is straightforward to check that $\Gamma_0$ satisfies...
the condition (i–v), \(|\Omega_{\Gamma_0}| = 1\), and \(\Theta_0\) satisfies the boundary condition (1.7). Then we compute the energy directly

\[
E(\Gamma_0) = \int_{-\pi}^{\pi} \sqrt{1 + \left(\frac{df_0}{dx}\right)^2} \, dx + \int_{-\pi}^{\pi} \int_0^{\cos x + 1/2} |\partial_x \Theta_0|^2 + |\partial_x \Theta_0|^2 \, dy \, dx
\]

\[
= \int_{-\pi}^{\pi} \left\{ \sqrt{1 + \frac{\sin^2 x}{4\pi^2}} + \frac{2\pi |\arctan(\frac{\sin x}{2\pi})|^2}{\cos x + 1}
\right. \\
\left. + \frac{\frac{\cos x(\cos x + 1)}{2\pi(1 + \frac{\sin^2 x}{4\pi^2})} + \arctan(\frac{\sin x}{2\pi}) \cdot \sin x}{6\pi(\cos x + 1)} \right\} \, dx
\]

\[
\leq C,
\]

where \(C\) is a constant. To see the integral is finite, we only need to examine the integrand when \(\cos x + 1 \to 0\), that is, \(x \to \pm \pi\). Assume \(x = \pi - \alpha\) for \(0 < \alpha < 1\), then \(\cos x + 1 \approx \frac{1}{2} \alpha^2\), \(|\arctan(\frac{\sin x}{2\pi})| \approx \frac{\alpha}{2\pi}\) and \(\sin x \approx \alpha\). It follows that the integrand is uniformly bounded on \(x \in (-\pi, \pi)\), which implies the finiteness of the integral.

Therefore, we have verified that \(\Gamma_0 \in \mathcal{G}_1\). And if Problem 1.5 admits a global minimizer \(\Gamma_m\), then we get the following upper bound for the energy infimum:

\[
M := E(\Gamma_0) \geq E(\Gamma_m).
\]

The next lemma tells us that the minimizing curve \(\Gamma_m\), if exists, will not touch \(x\)-axis besides two endpoints, which means that \(\Omega_m\) is simply connected.

**Lemma 2.1.** If \(\Gamma_m\) is the global minimizer of \(E(\Gamma)\) among all \(\Gamma \in \mathcal{G}_1\) and it is parameterized by arc length as in condition (i–v), then for any \(t \in (0, l(\Gamma_m))\), we have \(y(t) > 0\).

**Proof.** The proof is by contradiction. Assume \(y(t_0) = 0\) for some \(t_0 \in (0, l(G(m)))\), then the point \((x(t_0), y(t_0))\) cuts \(\Gamma_m\) into two parts, which are denoted by \(\Gamma_1\) and \(\Gamma_2\), respectively. We call the domain enclosed by \(\Gamma_i\) and \(x\)-axis as \(\Omega_i\) for \(i = 1, 2\). Let \(\alpha := |\Omega_1|\). We can further assume that \(\alpha \in (0, 1)\), because if \(\alpha = 0\) or 1, then one of \(\Gamma_i\) will coincide with the \(x\)-axis which contradicts with the fact that \(\Gamma_m\) is a minimizer. To see this, assume \(\Gamma_1\) coincides with the \(x\)-axis, then we can remove \(\Gamma_1\) from \(\Gamma_m\) and find that the remaining curve \(\Gamma_2\) still belongs to \(\mathcal{G}_1\) and \(E(\Gamma_2)\) is strictly less than \(E(\Gamma_m)\). Now we set

\[
\tilde{\Gamma}_1 = \frac{1}{\sqrt{\alpha}} \Gamma_1, \quad \tilde{\Omega}_1 = \frac{1}{\sqrt{\alpha}} \Omega_1, \quad \tilde{\Theta}_1 \left( \frac{x}{\sqrt{\alpha}}, \frac{y}{\sqrt{\alpha}} \right) = \Theta_m(x, y) \text{ for } (x, y) \in \Omega_1
\]

\[
\tilde{\Gamma}_2 = \frac{1}{\sqrt{1-\alpha}} \Gamma_2, \quad \tilde{\Omega}_2 = \frac{1}{\sqrt{1-\alpha}} \Omega_2, \quad \tilde{\Theta}_2 \left( \frac{x}{\sqrt{1-\alpha}}, \frac{y}{\sqrt{1-\alpha}} \right) = \Theta_m(x, y) \text{ for } (x, y) \in \Omega_2.
\]
We can check that for $i = 1, 2$, $(\tilde{F}_i, \tilde{\Omega}_i, \tilde{\Theta}_i)$ are energy competitors (after some horizontal translations) for $(\Gamma_m, \Omega_m, \Theta_m)$. By basic scaling property we get

$$l(\tilde{F}_1) = \frac{1}{\sqrt{\alpha}} l(\Gamma_1), \quad l(\tilde{F}_2) = \frac{1}{\sqrt{1 - \alpha}} l(\Gamma_2),$$

$$\int_{\tilde{\Omega}_i} |\nabla \tilde{\Theta}_i|^2 = \int_{\Omega_i} |\nabla \Theta|^2 \quad \text{for} \quad i = 1, 2.$$

The minimizing property yields

$$\frac{1}{\sqrt{\alpha}} l(\Gamma_1) + \int_{\Omega_1} |\nabla \Theta|^2 \geq l(\Gamma_1) + l(\Gamma_2) + \int_{\Omega_1} |\nabla \Theta|^2 + \int_{\Omega_2} |\nabla \Theta|^2,$$

$$\frac{1}{\sqrt{1 - \alpha}} l(\Gamma_2) + \int_{\Omega_2} |\nabla \Theta|^2 \geq l(\Gamma_1) + l(\Gamma_2) + \int_{\Omega_1} |\nabla \Theta|^2 + \int_{\Omega_2} |\nabla \Theta|^2.$$

Combining these two inequalities, we arrive at

$$l(\Gamma_1) \geq \frac{\sqrt{\alpha}}{1 - \sqrt{\alpha}} l(\Gamma_2) \geq \frac{\sqrt{\alpha}}{1 - \sqrt{\alpha}} \cdot \frac{\sqrt{1 - \alpha}}{1 - \sqrt{1 - \alpha}} l(\Gamma_1),$$

$$\Rightarrow \sqrt{\alpha}(1 - \alpha) \leq (1 - \sqrt{\alpha})(1 - \sqrt{1 - \alpha}) \Rightarrow \alpha = 0 \text{ or } 1,$$

which yields a contradiction. \qed

We define the following “two-point condition”:

**Definition.** A rectifiable curve $\Gamma$ is said to satisfy the “two-point condition” if and only if there is a constant $C > 0$ such that for any $z_1, z_2 \in \Gamma$, it holds that $\operatorname{diam} \gamma_{z_1 z_2} \leq C|z_1 - z_2|$, where $\gamma_{z_1 z_2}$ denotes the arc of $\Gamma$ between $z_1, z_2$ (if there are two arcs, take the one with smaller length).

Now we want to prove some geometric properties of $\Gamma \in \mathcal{G}_1$ (not necessarily a minimizer). The next statement says that for any three points on $\Gamma$, they are supposed to satisfy a reversed triangle inequality, with a constant depending only on $E(\Gamma)$.

**Lemma 2.2.** If $\Gamma \in \mathcal{G}_1$ and $E(\Gamma) \leq M$, then there exists a constant $C = C(M)$ such that for any three points $z_1 = (x(t_1), y(t_1))$, $z_2 = (x(t_2), y(t_2))$ and $z_3 = (x(t_3), y(t_3))$ on $\Gamma$ such that $t_1 < t_2 < t_3$, it holds that

$$\max \{\operatorname{dist}(z_1, z_2), \operatorname{dist}(z_2, z_3)\} \leq C \operatorname{dist}(z_1, z_3). \quad (2.9)$$

Moreover, $\Gamma$ satisfies the “two-point condition.”

**Proof.** By definition, the “two-point condition” follows directly from (2.9). So we just prove (2.9). Assume $C$ is a large enough number (say larger than 100) which will be determined later. We simply write $(x(t_i), y(t_i))$ as $(x_i, y_i)$ for $i = 1, 2, 3$. Then, for the value of $y_2$, there are three cases:

1. $\max\{y_1, y_3\} \geq y_2 \geq \min\{y_1, y_3\},$
2. $y_2 > \max\{y_1, y_3\},$
3. \( \min\{y_1, y_3\} > y_2 \).

The inequality (2.9) for the first case is trivial, because by simple geometry we can get

\[
\max \{\text{dist}(z_1, z_2), \text{dist}(z_2, z_3)\} \leq \text{dist}(z_1, z_3).
\]

Now we study the second case and assume (2.9) is false. By triangle inequality, we have

\[
\min \{\text{dist}(z_1, z_2), \text{dist}(z_2, z_3)\} \geq (C - 1)\text{dist}(z_1, z_3).
\]

Therefore, it holds that

\[
\min\{y_2 - y_1, y_2 - y_3\} \geq (C - 2)|x_1 - x_3|.
\]

For convenience we assume \( y_2 = \max_{t \in (t_1, t_2)} y(t) \). Otherwise we can take \( z_2 \) to be the point with the maximum value of \( y \) on \( z_1 \) and \( z_3 \). Note that such choice will not violate any of the above estimates.

We set the curve \( \Gamma \) between \( z_1, z_2 \) and \( z_2, z_3 \) as \( \Gamma_1, \Gamma_2 \), written as \( \Gamma_1 := \Gamma_{z_1z_2}, \Gamma_2 := \Gamma_{z_2z_3} \). Set \( l_i := l(\Gamma_1) \) for \( i = 1, 2 \). Also we reparameterize \( \Gamma_1 \) and \( \Gamma_2 \) as follows:

\[
\Gamma_1 := \{(x(s), y(s)) : s \in [0, l_1], (x(0), y(0)) = (x_2, y_2), (x(l_1), y(l_1)) = (x_1, y_1), x'(s) \leq 0, |x'(s)|^2 + |y'(s)|^2 = 1 \text{ almost everywhere}\},
\]

\[
\Gamma_2 := \{(x(s), y(s)) : s \in [0, l_2], (x(0), y(0)) = (x_2, y_2), (x(l_2), y(l_2)) = (x_3, y_3), x'(s) \geq 0, |x'(s)|^2 + |y'(s)|^2 = 1 \text{ almost everywhere}\}.
\]

Note that for such reparameterization, \( \Gamma_1 \) starts at \( z_2 \) and ends at \( z_1 \), while \( \Gamma_2 \) starts at \( z_2 \) and ends at \( z_3 \). Also we have \( \Theta(x(s), y(s)) = -\arcsin y'(s) \) on \( \Gamma_1 \) and \( \Theta(x(s), y(s)) = \arcsin y'(s) \) on \( \Gamma_2 \).

We first look at \( \Gamma_1 \). Set

\[
\tilde{r}(s) := \sqrt{|x(s) - x_2|^2 + |y(s) - y_2|^2}, \quad s \in [0, l_1],
\]

\[
I(r) := \{s \in [0, l_1] : \tilde{r}(s) = r\}.
\]

For \( 0 < r < |z_1 - z_2| \), the circle \( \{|z - z_2| = r\} \) will intersect with \( \Gamma_1 \), and therefore, \( I_r \) is not empty. By definition, we have

\[
\int_0^{l_1} y'(s) \, ds = y_1 - y_2, \quad (2.10)
\]

\[
\int_0^{l_1} x'(s) \, ds = x_1 - x_2. \quad (2.11)
\]

For \( \tilde{r}(s) \), we can estimate its derivative by

\[
|\tilde{r}'(s)| = \left| \frac{(x(s) - x_2) \cdot x'(s) + (y(s) - y_2) \cdot y'(s)}{r(s)} \right| \leq \sqrt{|x'(s)|^2 + |y'(s)|^2} = 1.
\]
Then by the coarea formula, we have
\[ l_1 \geq \int_0^{l_1} |\tilde{r}'(s)| \, ds = \int_0^{[z_1 - z_2]} \mathcal{H}^0(I_r) \, dr. \]

This tells us that for almost every \( r \in [0, |z_1 - z_2|] \), \( \mathcal{H}^0(I_r) \) is finite. Note that \( \mathcal{H}^0 \) is just the counting measure, and we will simply write it as \( |I_r| \). Denote by \( A \) the subset of \([0, l_1]\) such that for any \( s \in A \), \( \tilde{r}'(s) = 0 \). Again coarea formula gives
\[ 0 = \int_A |\tilde{r}'(s)| \, ds = \int_0^{[z_1 - z_2]} \mathcal{H}^0(A \cap I_r) \, dr, \]
so \( A \cap I_r = \emptyset \) for almost everywhere \( r \in [0, |z_1 - z_2|] \). We define
\[ R_0 := \{ r \in [0, |z_1 - z_2|] : |I_r| \text{ is finite, and } |\tilde{r}'(s)| > 0 \text{ for any } s \in I_r \}. \]
We have \( m([0, |z_1 - z_2|]\backslash R_0) = 0 \). For any \( r \in R_0 \), we pick a representative from \( I_r \) in the following way:
\[ s' = \min\{s : s \in I_r\}. \]
We define the following two subsets:
\[ R_1 := \{ r \in [2|z_1 - z_3|, |z_1 - z_2|] \cap R_0 : x'(s') \leq -1/2 \}, \]
\[ R_2 := ([2|z_1 - z_3|, |z_1 - z_2|] \cap R_0) \backslash R_1. \]
Note that \( R_1 \) corresponds to the part of curve on \( \Gamma_1 \) where is not “too vertical.” Using coarea formula again, we get
\[ \frac{1}{2} m(R_1) \leq \left| \int_{R_1} \frac{dx(s')}{ds} \cdot \left| \frac{dr(s')}{ds} \right|^{-1} \, dr \right| \leq \left| \int_{\Gamma^{-1}(R_1)} x'(s) \, ds \right| \leq |x_1 - x_2|. \]
As a consequence, we get
\[ m(R_2) \geq |z_1 - z_2| - 2|z_1 - z_3| - 2|x_1 - x_2| \geq |z_1 - z_2| - 4|z_1 - z_3|. \tag{2.12} \]
Now we make the following observation:
\[ \text{For any } r \in R_2, y'(s') < -\frac{\sqrt{3}}{2}. \]
This is a consequence of definition of \( R_2 \) and \( s' \). Since \( r \in R_2 \), we have
\[ y'(s') > \frac{\sqrt{3}}{2} \text{ or } y'(s') < -\frac{\sqrt{3}}{2}, \]
\[ y(s') < y_2 - \sqrt{3}|z_1 - z_3|, \quad x_2 - |z_1 - z_3| \leq x(s') < x_2, \]
\[ |y(s') - y_2| > \sqrt{3}|x(s') - x_2|. \]

We also have that \( \frac{df(s')}{ds} > 0 \) because \((x(s'), y(s'))\) is the first point that \( \Gamma_1 \) touches \( \{|z - z_2| = r\}\). If \( y'(s') > \frac{\sqrt{3}}{2} \), then
\[
\tilde{r}'(s') = \frac{x'(s')(x(s') - x_2) + y'(s')(y(s') - y_2)}{r} < 0,
\]
which yields a contradiction. Therefore, we have verified the observation.

Now we deal with \( \Gamma_2 \) in the same way with several minor modifications. We can show that there exists a \( R_3 \) such that
\[
R_3 \subset \{2|z_1 - z_3|, |z_2 - z_3|\}, \quad m(R_3) \geq |z_2 - z_3| - 4|z_1 - z_3|,
\]
and \( \forall r \in R_3, \; y'(s_r) < -\frac{\sqrt{3}}{2} \).

Here \( s_r \) is the point that \( \Gamma_2 \) first touches \( \{|z - z_2| = r\} \).

We are now ready to derive a contradiction. Denoting \( R := R_2 \cap R_3 \), then we have
\[
R \subset \{r : 2|z_1 - z_3| \leq r \leq \min\{|z_1 - z_2|, |z_2 - z_3|\}\},
\]
\[
m(R) \geq \min\{|z_1 - z_2|, |z_2 - z_3|\} - 8|z_1 - z_3|.
\]

For any \( r \in R \), \( \Gamma_1 \) first intersects \( \{|z - z_2| = r\} \) at \( z_1(r) := (x(s'), y(s')) \) and \( \Gamma_2 \) first intersects with \( \{|z - z_2| = r\} \) at \( z_2(r) := (x(s_r), y(s_r)) \). The arc \( z_1(r)z_2(r) \) is contained in \( \Omega_r \) because of the definitions of \( s', s_r \). Moreover, \( \Theta = -\arcsin y'(s') > \frac{\pi}{3} \) at \( z_1(r) \) and \( \Theta = \arcsin y'(s_r) < -\frac{\pi}{3} \) at \( z_2(r) \). Then we are ready to estimate the Dirichlet energy of \( \Theta \) in \( \Omega_r \),
\[
\int_{\Omega_r} |\nabla \Theta|^2 \, dx \, dy \geq \int_0^{C|z_1 - z_3|} dr \int_{\{|z - z_2| = r\} \cap \Omega_r} |\nabla \Theta(z_2 + re^{i\theta})|^2 \, r \, d\theta
\]
\[
\geq \int_0^{C|z_1 - z_3|} dr \int_{\{\theta: z_2 + re^{i\theta} \in \Omega_r\}} \left| \frac{\partial \Theta(z_2 + re^{i\theta})}{\partial \theta} \right|^2 \frac{1}{r} \, d\theta
\]
\[
\geq \int_{r \in R} \frac{|\Theta(z_1(r)) - \Theta(z_2(r))|^2}{\pi r} \, dr
\]
\[
\geq \int_{|z_1 - z_3|}^{(C-1)|z_1 - z_3|} \frac{4\pi}{9} \frac{1}{r} \, dr
\]
\[
\geq \log \frac{C - 1}{8}.
\]

Here, from the second line, to the third line we use the Cauchy–Schwarz inequality to estimate the integral with respect to \( \theta \).

Now, by choosing \( C \) satisfying \( \log \frac{C - 1}{8} \geq 2M \), we arrive at a contradiction with the energy bound. Thus, we have proved (2.9) for case (2).

For case (3) when \( \min\{|y_1, y_3| \geq y_2 \) \}, the proof follows similar arguments. Assume \( y_2 = \min_{t \in [t_1, t_3]} y(t) \). We still call the curve between \( z_1, z_2 \) and \( z_2, z_3 \)
as \( \Gamma_1, \Gamma_2 \) and reparameterize them as before. And \( \tilde{r}(s), I(r), R_0, s^r, s_r, z_1(r), z_2(r) \) are all defined in the same way. Recall that \( z_1(r) := (x(s^r), y(s^r)) \in \Gamma_1 \) and \( z_2(r) := (x(s_r), y(s_r)) \in \Gamma_2 \). Similarly, we can find \( R_2 \subset [2|z_1 - z_3|, |z_1 - z_2|] \) such that for any \( r \in R_2, \Theta(z_1(r)) < -\frac{\pi}{3} \). Also there exists \( R_3 \subset [2|z_1 - z_3|, |z_1 - z_3|] \) such that for \( r \in R_3, \Theta(z_2(r)) > \frac{\pi}{3} \).

Now we claim that, for any \( r \in R := R_2 \cap R_3 \), it holds that

\[
\int_{\{|z - z_2| = r\} \cap \Omega_r} |\nabla \Theta (z_1 + re^{i\theta})|^2 r \, d\theta \geq \frac{C_1}{r}. \tag{2.14}
\]

Here \( C_1 \) is a constant that can be chosen as \( \frac{\pi}{18} \). This is the place where case (3) differs from case (2), because in case (2) the set \( \{|z - z_2| = r\} \cap \Omega_r \) is just the arc \( z_1(r)z_2(r) \). However, in case (3), \( \{|z - z_2| = r\} \cap \Omega_r \) is more complicated. We prove the claim by discussing following three situations (see Fig. 2):

1. \( \{|z - z_2| = r\} \) only intersects with \( \Gamma \) at \( z_1(r), z_2(r) \) and does not intersect with \( x \)-axis. Since \( \Theta(z_1(r)) < -\frac{\pi}{3} \) and \( \Theta(z_2(r)) > \frac{\pi}{3} \), we have

\[
\int_{\{|z - z_2| = r\} \cap \Omega_r} |\nabla \Theta (z_2 + re^{i\theta})|^2 \, d\theta \geq \frac{1}{r} \int_{z_2 + re^{i\theta} \in \Omega_r} |\frac{\partial \Theta}{\partial \theta}|^2 d\theta \geq \frac{C_1}{r}.
\]

2. \( \{|z - z_2| = r\} \) only intersects with \( \Gamma \) at \( z_1(r), z_2(r) \) and also intersects with \( x \)-axis at \( z_3(r) \). Without loss of generality we can assume the arc \( z_1(r)z_3(r) \) is contained in \( \Omega_f \). Then since \( \Theta = 0 \) on \( x \)-axis, we have \( |\Theta(z_1(r)) - \Theta(z_3(r))| \geq \frac{\pi}{3} \); then, we can verify (2.14) by the same calculation.

3. \( \{|z - z_2| = r\} \) intersects with \( \Gamma \) at more than two points. Let \( z_3(r) = (x_3(r), y_3(r)) \) be another point of intersection besides \( z_1(r), z_2(r) \). Without loss of generality, we assume \( x_3(r) < x_1(r) \). In our construction, we make sure that \( r'(s^r) > 0 \) at \( z_1(r) \). And we can assume \( \overline{z_1(r)z_3(r)} \subset \overline{\Omega_f} \). Therefore, we have \( \Theta(z_3(r)) \geq 0 \) because at \( z_3(r), \Gamma'(t) \) is “leaving” the disk \( \{|z - z_2| \leq r\} \) as \( t \) increases. This implies that \( |\Theta(z_1(r)) - \Theta(z_3(r))| \geq \frac{\pi}{3} \). Then (2.14) follows immediately in the same way.

With (2.14), we can repeat the computation in (2.13) and finally verifies (2.9) for case (3). This completes our proof of Lemma2.2. \( \Box \)

It was proved by Ahlfors in [1] that a Jordan curve is a quasicircle if and only if it satisfies the “two-point condition.” A quasicircle is the image of the unit circle \( \mathbb{T} \) under a quasiconformal mapping of the complex plane onto itself. And in 2D a quasidisk (domain enclosed by a quasicircle) is equivalent to a Sobolev extension domain, see [22]. However, in our problem, \( \partial \Omega_r = \Gamma \cap \{(x,0): x \in [-a,a]\} \) is not a quasicircle because near two endpoints \((-a,0) \) and \((a,0)\) the “two-point condition” will be violated. The next lemma says that even though we cannot directly use the property of a quasidisk, we can still extend \( \Theta \) to the whole plane with a uniform control on its \( H^1 \)-norm.

**Lemma 2.3.** (Extension domain) Assume \( \Gamma \in \mathcal{G}_1 \) and \( E(\Gamma) \leq M \), then there exists a constant \( C_2 \) that depends on \( M \) such that \( \Theta|_{\overline{\Omega_r}} \) can be extended to the whole plane with a norm control

\[
\|\Theta\|_{H^1(\mathbb{R}^2)} \leq C_2 \|\Theta\|_{H^1(\Omega_r)}.
\]
Fig. 2. Three different situations of $I_r$ and $\{|z - z_2| = r\} \cap \Omega_r$, when $\min\{y_1, y_3\} > y_2$
The idea of the proof is to glue a rectangle together with $\Omega_\Gamma$ to make the combined domain a quasidisk. Assume the intersection points of $\Gamma$ and $x$-axis are $(-a, 0)$ and $(a, 0)$, we set

$$D_1 := \{(x, y) : -a < x < a, \ -a < y \leq 0\}, \quad D_\Gamma = \Omega_\Gamma \cup D_1.$$  

We claim that $D_\Gamma$ is a quasidisk. For any two points $z_1, z_2 \in \partial D_\Gamma$, if $z_1, z_2 \in \Gamma$, then Lemma 2.2 says they satisfy the “two-point condition.” If $z_1, z_2 \in \partial D_1 \cap \partial D_\Gamma$, they automatically satisfy the “two-point condition” because a rectangle is a quasidisk. Thus, we are left with the case $z_1 \in \Gamma$, $z_2 \in \partial D_1 \cap \partial D_\Gamma$. In such a case, there are two situations:

1. $z_2 \in \{(x, -a) : -a \leq x \leq a\}$. Then $|z_1 - z_2| \geq a$ and Lemma 2.2 implies that $\diam(D_\Gamma) \leq (C + 2)a$ where $C$ is the constant in (2.9). So the “two-point condition” holds for this situation.

2. $z_2 \in \{-(a, y) : -a \leq y \leq 0\} \cup \{(a, y) : -a \leq y \leq 0\}$. Without loss of generality we assume $z_2 = (a, y)$ and set $z_0 := (-a, 0)$. Let $\gamma$ be the arc of $\Gamma$ between $z_0$ and $z_1$, then we get

$$|z_1 - z_2| \geq \max(|y|, |z_1 - z_0|), \quad \diam(\overline{z_2z_0} \cup \gamma) \leq |y| + \diam(\gamma),$$

where $\overline{z_2z_0}$ is the line segment between $z_0$ and $z_2$. One can easily shows that $\diam(\overline{z_2z_0} \cup \gamma) \leq (C + 1)|z_1 - z_2|$, since $\diam \gamma \leq C|z_1 - z_0|$ by (2.9). The “two-point condition” is verified.

Therefore, by Ahlfors’ result, we prove the claim. Next we can trivially extend $\Theta$ to $D_\Gamma$ by letting $\Theta(x, y) \equiv 0$ for $(x, y) \in D_1$, because $\Theta$ vanishes on $\{(x, 0) : -a \leq x \leq a\}$. Obviously, $\|\Theta\|_{H^1(D_\Gamma)} = \|\Theta\|_{H^1(\Omega_\Gamma)}$. Moreover, we can further extend $\Theta$ to the whole plane $\mathbb{R}^2$, since a 2D domain is a quasidisk if and only if it is a Sobolev extension domain. Also from the above derivation and the proof of Lemma 2.2, the constant $C$ in the “two-point condition” for $\partial D_\Gamma$ only depends on $M$. By [22, Theorem C and Theorem 4] and [33, Theorem 2.24], we can show that the norm of the extension operator only depends on $M$, that is, there is a $C_2 := C_2(M)$ such that

$$\|\Theta\|_{H^1(\mathbb{R}^2)} \leq C_2\|\Theta\|_{H^1(\Omega_\Gamma)}.$$  

This completes our proof of Lemma 2.3. □

2.2. $\Gamma$ is a Chord–Arc curve

We will give more geometric properties of $\Gamma$ by showing that it is a chord–arc curve, which means the length of the chord is comparable with the length of the arc (see [21] for a detailed discussion on chord–arc curves).

**Proposition 2.4.** Let $\Gamma \in \mathcal{G}_1$ and $E(\Gamma) \leq M$. There exists a constant $C_3(M)$ such that for any two points $z_1, z_2 \in \Gamma$ and the arc $\gamma := \Gamma_{z_1z_2}$, we have

$$l(\gamma) < C_3|z_1 - z_2|.$$  

In other words, $\Gamma$ is a chord–arc curve.
First assume $C_3$ is a very large number that will be determined later. We prove by contradiction. Suppose $\mathcal{H}_1(\gamma) = c|z_1 - z_2|$ for some $c > C_3$, our goal is to show that the Dirichlet energy “generated” by this part of boundary will be very large, which contradicts to the uniform bounds of Dirichlet energy ($E(\Gamma) \leq M$).

The basic idea can be roughly stated as follows: If the length of curve is way too long compared with the chord length, then there will be lots of fluctuations of the curve, which will lead to large energy. The coarea formula will be used repeatedly in the proof.

Since 2D Dirichlet energy is scaling invariant, we simply let $|z_1 - z_2| = 1$ and reparameterize the curve $\gamma$ in the following way:

$$
\gamma = \{(x(t), y(t)) : x, y \in AC[0, c]; x'(t) \geq 0; z_1 = (x(0), y(0)) = (0, 0),
$$

$$
z_2 = (x(c), y(c)) = (a, \pm \sqrt{1-a^2}) \text{ for some } a \in (0, 1]; |x'(t)|^2 + |y'(t)|^2 = 1 \text{ almost everywhere}\}.
$$

According to Lemma 2.2, we have $|y(t)| \leq C$ for $t \in [0, c]$, where $C$ is the constant in (2.9). So there exists $Y_1 \leq 0, Y_2 \geq 0$ such that $|Y_i| \leq C$ for $i = 1, 2$ and $\min y(t) = Y_1, \max y(t) = Y_2$. Furthermore, we have

$$
\Gamma \subset [0 \leq x \leq a, Y_1 \leq y \leq Y_2] =: Q. \quad (2.15)
$$

We have the following upper bound for the energy:

$$
\int_{\Omega_\gamma} |\nabla \Theta|^2 \, dx \, dy \leq M, \text{ where } \Omega_\gamma := Q \cap \{(x, y) \text{ below } \gamma\}.
$$

Note that by Lemma 2.3, we can extend the domain of $\Theta$ to all of $Q$ such that

$$
\int_Q |\nabla \Theta|^2 \, dx \, dy \leq C_2 M =: C_4.
$$

Here this constant $C_4$ only depends on $M$. Also we make the following definitions:

$$
T_s := \{t \in [0, c] : y(t) = s\}, \quad \forall s \in [Y_1, Y_2]
$$

$$
U := \{s \in [Y_1, Y_2] : |T_s| \text{ is infinite}\}, \quad W := \{t \in [0, c] : y(t) \in U\}.
$$

$$
S := \{s \in [Y_1, Y_2] : |T_s| = 1\}, \quad A := \{t \in [0, c] : y(t) \in S\}.
$$

$$
V := [Y_1, Y_2] \setminus (S \cup U), \quad B := [0, c] \setminus (A \cup W).
$$

Here $| \cdot |$ denotes the cardinality of a set.

Now we have set up all the assumptions and are ready to derive a contradiction. First we point out several elementary observations:

(i) The following estimate holds:

$$
\int_0^c |y'(t)|^2 \, dt = c - \int_0^c |x'(t)|^2 \, dt \geq c - 1, \quad (2.16)
$$

where we have used $x'(t) \geq 0$ and $\int_0^c x'(t) \leq 1.$
(ii) If $Y_2 > 1$, then for any $s \in [1, Y_2)$, we have $|T_s| \geq 2$ by mean value theorem for continuous function. Similarly, if $Y_1 < -1$, for any $s \in (Y_1, -1]$, it holds that $|T_s| \geq 2$. In other words, we have

$$S \subset [-1, 1] \cap \{Y_1, Y_2\}.$$ 

(iii) We can estimate the measure of $A$ by

$$m(A) = \int_A \sqrt{\left| x'(t) \right|^2 + \left| y'(t) \right|^2} \, dt$$

$$\leq \int_A \left| x'(t) \right| \, dt + \int_A \left| y'(t) \right| \, dt$$

$$\leq 1 + \int_S \mathcal{H}^0(T_s) \, ds \text{ (by coarea formula)}$$

$$= 1 + |S| \leq 3.$$ 

(2.17)

(iv) By coarea formula, one can easily check that

$$m(U) = 0, \quad \int_W |y'(t)| \, dt = 0$$

For any $s \in V$, by definition we have $2 \leq T_s < \infty$, we want to derive a lower bound for the following quantity:

$$E(s) := \int_0^a |d_x \Theta(x, s)|^2 \, dx.$$ 

Assume $T_s = \{t_1, \ldots, t_n\}$ for some $n \geq 2$, and by definition, we have

$$\sin(\Theta(x(t_i), s)) = y'(t_i), \quad \text{for } i = 1, \ldots, n.$$ 

An easy observation is that for each two adjacent points, say $t_i$ and $t_{i+1}$,

$$y'(t_i) \cdot y'(t_{i+1}) \leq 0.$$ 

We deduce that

$$|\Theta(x(t_i), s) - \Theta(x(t_{i+1}), s)|$$

$$\geq |\sin(\Theta(x(t_i), s)) - \sin(\Theta(x(t_{i+1}), s)| = \left| y'(t_i) \right| + \left| y'(t_{i+1}) \right|.$$ 

Then we estimate $E(s)$ as follows:

$$E(s) = \int_0^a |d_x \Theta(x, s)|^2 \, dx$$

$$\geq \sum_{i=1}^{n-1} \int_{x(t_i)}^{x(t_{i+1})} |d_x \Theta(x, s)|^2 \, dx$$

$$\geq \sum_{i=1}^{n-1} \int_{x(t_i)}^{x(t_{i+1})} \left| \frac{\Theta(x(t_{i+1}), s) - \Theta(x(t_i), s)}{x(t_{i+1}) - x(t_i)} \right|^2 \, dx.$$
\begin{align*}
\sum_{i=1}^{n-1} \frac{(|y'(t_i)| + |y'(t_{i+1})|)^2}{x(t_{i+1}) - x(t_i)} \\
\geq \frac{\left(\sum_{i=1}^{n} |y'(t_i)|\right)^2}{x(t_n) - x(t_1)} \\
\geq \sum_{t \in T_s} |y'(t)|^2.
\end{align*}
(Cauchy–Schwarz) \hfill (2.18)

Using the coarea formula, we get
\[ \int_B |y'(t)|^3 \, dt = \int_U \left( \sum_{t \in T_s} |y'(t)|^2 \right) \, ds. \tag{2.19} \]

Then by estimating the Dirichlet energy inside \( Q \) using (2.18) and (2.19), we have that
\[ C_4 \geq \int_Q |\nabla \Theta(x, y)|^2 \, dx \, dy \\
\geq \int_V E(s) \, ds \\
\geq \int_V \left( \sum_{t \in T_s} |y'(t)|^2 \right) \, ds \\
= \int_B |y'(t)|^3 \, dt. \tag{2.20} \]

Hölder inequality further implies that
\[ \left( \int_B |y'(t)|^3 \, dt \right)^{3/2} \geq \left( \int_B |y'(t)|^2 \, dt \right)^{3/2} \cdot m(B)^{-1/2}. \tag{2.21} \]

By (2.16) and (2.17), we have that
\[ \int_B |y'(t)|^2 \, dt \geq c - 1 - \int_A |y'(t)|^2 \, dt - \int_W |y'(t)|^2 \, dt \geq c - 4. \tag{2.22} \]

As a result, combining (2.20), (2.21) and (2.22) leads to
\[ C_4 \geq \frac{(c - 4)^{3/2}}{c^{1/2}}, \]
which yields a contradiction if we choose the constant \( C_3 \) to be large enough at first (recall that \( c \) is a real number larger than \( C_3 \)). Now that since \( C_4 \) only depends on \( M \), \( C_3 \) also only depends on \( M \). This completes our proof of Proposition 2.4. \( \square \)

Actually, we can examine the chord–arc property of \( \Gamma \) more closely and prove that it is indeed a vanishing chord–arc (also called “approximately smooth”) curve, which is the following lemma:
Proposition 2.5. Let $\Gamma \in \mathcal{G}_1$ and $E(\Gamma) \leq M$. For any $\varepsilon > 0$, there exists a $r = r(\varepsilon, \Gamma)$ such that for any two points $z_1, z_2 \in \Gamma$ that satisfy $|z_1 - z_2| \leq r$, we have

$$l(\gamma) \leq (1 + \varepsilon)|z_1 - z_2|,$$

where $\gamma = \Gamma_{z_1z_2}$. That is to say, $\Gamma$ is a vanishing chord–arc (approximately smooth) curve.

Proof. The technique here will be very similar to the proof of Proposition 2.4. We will only present our main ingredients and omit some computational details. Take any $z_1, z_2 \in \Gamma$ such that $|z_1 - z_2| = r$. By Lemma 2.2, $\gamma = \Gamma_{z_1z_2}$ must be contained in a rectangular domain $Q_{z_1z_2}$ with width $r$ and length $2Cr$ (see (2.15) for the existence of such rectangle). Let $\Theta$ be the angle function determined by $\Gamma$, we again extend $\Theta$ to $\mathbb{R}^2$ such that $\int_{\mathbb{R}^2} |\nabla \Theta|^2 \, dx < C_2M$. Then for any $\delta > 0$, there exists a $\sigma > 0$ such that

$$\int_E |\nabla \Theta|^2 \, dx \leq \delta, \quad \text{whenever } |E| < \sigma.$$

Therefore, as $r \to 0$, the Dirichlet energy of $\Theta$ inside $Q_{z_1z_2}$ will go to zero. The convergence rate does not depend on the choice of $z_1, z_2$ but only depends on their distance $r$. As a consequence, in order to prove the lemma, we only need to prove the following statement: For any $\varepsilon > 0$, there exists a constant $C(\varepsilon) > 0$ such that

$$\int_{Q_{z_1z_2}} |\nabla \Theta|^2 \, dx \geq C(\varepsilon), \quad \text{whenever } l(\gamma) \geq (1 + \varepsilon)|z_1 - z_2| \quad (2.23)$$

Now we fix $\varepsilon > 0$. By scaling invariant property, we assume without loss of generality that $|z_1 - z_2| = 1$ and $l(\gamma) = 1 + \varepsilon$, $z_1 = (0, 0), z_2 = (\cos \alpha, \sin \alpha)$ for some $\alpha \in (0, \frac{\pi}{2})$. Note that here $|\alpha| \neq \frac{\pi}{2}$, otherwise $\gamma$ would be the line segment orthogonal to $x$-axis and $l(\gamma) = 1$. We parameterize $\gamma$ as

$$\gamma := \{(x, y) : (x(0), y(0)) = z_1, (x(1 + \varepsilon), y(1 + \varepsilon)) = z_2, |x'(t)|^2 + |y'(t)|^2 = 1, \text{ almost everywhere}\}$$

Set

$$h(t) := \cos \alpha \cdot y(t) - \sin \alpha \cdot x(t), \quad g(t) := \sin \alpha \cdot y(t) + \cos \alpha \cdot x(t).$$

We have

$$\int_0^{1+\varepsilon} x'(t) \, dt = \cos \alpha, \quad \int_0^{1+\varepsilon} y'(t) \, dt = \sin \alpha, \quad h(0) = h(1 + \varepsilon) = 0 \quad (2.24)$$

Set $h_{\max} = \max_{0 \leq t \leq 1+\varepsilon} h(t)$ and $h_{\min} = \min_{0 \leq t \leq 1+\varepsilon} h(t)$, and define

$$T_s := \{t \in [0, 1 + \varepsilon] : h(t) = s\} \text{ for } s \in [h_{\min}, h_{\max}],$$

$$B := \{t \in [0, 1 + \varepsilon] : 2 \leq T_{h(t)} < \infty\}.$$
Obviously for any \( s \in (h_{\min}, h_{\max}) \) we have \(|T_s| \geq 2\). Also we should deduct the subset of \([h_{\min}, h_{\max}]\) such that \(|T_s|\) is infinite (see the definition of set \( U, W \) in the proof of Proposition 2.4). But from the argument in the proof of Proposition 2.4 we know it is a measure zero set and would not affect our computation, so we may simply assume \( 2 \leq |T_s| < \infty \) for any \( s \in (h_{\min}, h_{\max}) \).

We discuss things in two cases.

**Case 1.** If \( g'(t) = \sin \alpha \cdot y'(t) + \cos \alpha \cdot x'(t) \geq 0 \) for almost everywhere \( t \in [0, 1 + \varepsilon] \). We firstly define

\[
\partial_g \Theta := \sin \alpha \partial_y \Theta + \cos \alpha \partial_x \Theta, \quad \partial_h \Theta := \cos \alpha \partial_y \Theta - \sin \alpha \partial_x \Theta.
\]

We calculate in the same way as (2.18), (2.19) and (2.20) (the only difference is we replace \( y(t) \) with \( h(t) \)) and obtain

\[
\int_{Qz_1 z_2} |\nabla \Theta|^2 \, dx \, dy \geq \int_{Qz_1 z_2} |\partial_g \Theta|^2 \, dx \, dy \geq C \int_B |h'(t)|^2 \, dt. \tag{2.25}
\]

Here \( C \) is a positive constant only depend on \( M \). Also, from (2.24) and the assumption \( g'(t) \geq 0 \) we have that

\[
\int_0^{1+\varepsilon} |\sin \alpha \cdot y'(t) + \cos \alpha \cdot x'(t)|^2 \, dt = \int_0^{1+\varepsilon} |(\sin \alpha \cdot y'(t) + \cos \alpha \cdot x'(t))| \cdot (\sin \alpha \cdot y'(t) + \cos \alpha \cdot x'(t)) \, dt \leq \int_0^{1+\varepsilon} (\sin \alpha \cdot y'(t) + \cos \alpha \cdot x'(t)) \, dt = 1 \tag{2.26}
\]

and

\[
\int_0^{1+\varepsilon} |\cos \alpha \cdot y'(t) - \sin \alpha \cdot x'(t)|^2 \, dt = 1 + \varepsilon.
\]

The above two inequalities imply that

\[
\int_0^{1+\varepsilon} |h'(t)|^2 \, dt \geq \varepsilon.
\]

By coarea formula, we know that the set where \( h(t) = h_{\min} \) or \( h_{\max} \) contributes nothing in the above integral, so we have

\[
\int_B |h'(t)|^2 \, dt \geq \varepsilon. \tag{2.27}
\]

Then we combine (2.25), (2.27) and Hölder inequality to conclude that

\[
\int_{Qz_1 z_2} |\nabla \Theta|^2 \, dx \, dy \geq C \frac{\varepsilon^{3/2}}{(1 + \varepsilon)^{1/2}}. \tag{2.28}
\]
Case 2. Assume \( g'(t) \geq 0 \) does not hold almost everywhere, then we may lose the estimate (2.26). If we still have \( \int_{0}^{1+\varepsilon} |g'(t)|^{2} \leq 1 \), then all the estimates in Case 1 still hold and there is nothing to prove. Thus, we assume

\[
\int_{0}^{1+\varepsilon} |g'(t)|^{2} \, dt = 1 + \delta \quad \text{for some } 0 < \delta \leq \varepsilon.
\]  

Then

\[
\int_{B} |h'(t)|^{2} \, dt = \varepsilon - \delta.
\]  

Then the same computation leads to

\[
\int_{B_{2}} |\partial_{\Theta} g|^2 \, dx \, dy \geq C \frac{(\varepsilon - \delta)^{3/2}}{(1 + \varepsilon)^{1/2}}.
\]  

Now we set

\[
g_{\max} := \max_{0 \leq t \leq 1+\varepsilon} g(t), \quad g_{\min} := \min_{0 \leq t \leq 1+\varepsilon} g(t),
\]

\[
The_s := \{ t \in [0, 1 + \varepsilon] : g(t) = s \} \text{ for } s \in [g_{\min}, g_{\max}],
\]

\[
B_2 := \{ t \in [0, 1 + \varepsilon] : 2 \leq |T_{g(t)}^{2}| < \infty \},
\]

\[
A_2 := \{ t \in [0, 1 + \varepsilon] : g'(t) < 0 \}.
\]

Again we can ignore the set where \( |T_{g(t)}^{2}| = \infty \) since it may lead to more complicated notations but would not affect any of our estimates. So we assume for every \( t \in [0, 1 + \varepsilon] \), we have \( |T_{g(t)}^{2}| < \infty \). Then simple geometry tells us that \( A_2 \subseteq B_2 \).

Also, since \( \int_{0}^{1+\varepsilon} g'(t) \, dt = 1 \) and \( \int_{0}^{1+\varepsilon} |g'(t)| \geq 1 + \delta \), it holds that

\[
\int_{B_2} |g'(t)| \, dt \geq \int_{A_2} |g'(t)| \, dt \geq \frac{\delta}{2}.
\]  

Similar techniques as to those in (2.18), (2.19) and (2.20) imply that

\[
\int_{Q_{z_1 z_2}} |\partial_{\Theta} g|^2 \, dx \, dy \geq C \int_{B_2} |g'(t)|^{3} \, dt \geq C \frac{(\delta/2)^{3}}{(1 + \varepsilon)^{2}}, \quad \text{(Hölder inequality)}
\]

where \( C \) is a constant that only depends on \( M \). We can combine this with (2.31) to get

\[
\int_{Q_{z_1 z_2}} |\nabla \Theta|^2 \, dx \, dy \geq C \int_{Q_{z_1 z_2}} |\partial_{\Theta} g|^2 \, dx \, dy + \int_{Q_{z_1 z_2}} |\partial_{\Theta} h|^2 \, dx \, dy
\]

\[
\geq C \left( \frac{(\varepsilon - \delta)^{3/2}}{(1 + \varepsilon)^{1/2}} + \frac{(\delta/2)^{3}}{(1 + \varepsilon)^{2}} \right)
\]

\[
\geq C(\varepsilon, M).
\]

This implies (2.23) and completes our proof of Proposition 2.5. \( \Box \)
Corollary 2.6. The normal vector $v$ along the curve $\Gamma$ belongs to VMO (vanishing mean oscillation space), that is,
\[
\lim_{r \to 0} \left( \frac{1}{l(B(x, r) \cap \Gamma)} \int_{B(x, r) \cap \Gamma} |v - v_{B(x, r)}| \, dl \right) = 0 \quad \text{uniformly for } x \in \Gamma,
\]
where
\[
v_{B(x, r)} = \frac{1}{l(B(x, r) \cap \Gamma)} \int_{B(x, r) \cap \Gamma} v \, dl.
\]

Proof. We already have that $\Gamma$ is a vanishing chord–arc curve. Then we can directly apply results of Kenig and Toro [25, Theorem 2.1] to conclude that $v \in \text{VMO}$. $\square$

### 2.3. Weil–Petersson curve and $H^{3/2}$ characterization

Recall that a quasicircle is the image of the unit circle $\mathbb{T}$ under a quasiconformal map $f$ of $\mathbb{R}^2$, that is, a homeomorphism of the plane that is conformal outside the unit disk $\mathbb{D}$, whose dilatation $\mu = f_z/f_{\bar{z}}$ satisfies $\|\mu\|_{L^\infty(\mathbb{D})} < 1$. The collection of planar quasicircles corresponds to the universal Teichmüller space $\mathcal{T}(1)$ and the metric is defined in terms of $\|\mu\|_{\infty}$. We refer to [18,19] for an introduction to the uniform Teichmüller space and more details. In Takhtajan and Teo [41] defined a Weil–Petersson metric on the universal Teichmüller space $\mathcal{T}(1)$ that makes it into a Hilbert manifold. A Weil–Petersson curve is the image of $\mathbb{T}$ under a quasiconformal map $f$ on the plane and satisfies $|\mu| \in L^2(dA_{\rho})$, where $dA_{\rho} = \frac{4}{(1-|z|^2)^2} d^2 z$ is the hyperbolic metric on $\mathbb{D}$ (see [8,41]). Another characterization for the Weil–Petersson curve is in terms of conformal mapping $f : \mathbb{D} \to \Omega$, where $\Omega$ is the domain bounded by $\Gamma$. $\Gamma$ is a Weil–Petersson curve if and only if $(\log f')' \in L^2(\mathbb{D})$ (see [41, Chapter 2]).

In our problem, the curves in $\mathcal{G}_{V}$ strongly resemble the Weil–Petersson curves in the following way. For a Weil–Petersson curve $\Gamma$, let $f : \mathbb{D} \to \Omega$ be a conformal mapping. We focus on the boundary map $f : \mathbb{T} \to \Gamma$. Since $\log f'$ is in the Dirichlet space, we have that $\text{arg} f'(z)$ (arg means the argument of a complex number) as a function on $\mathbb{T}$, has an extension with finite Dirichlet energy inside $\mathbb{D}$. One can check that for any $a \in \mathbb{T}$, it holds that $\text{arg} f'(a) = \text{arg} \nu_f (f(a)) - 2\pi a$, where $\nu_f (f(a))$ is the outer normal vector of $\Gamma$ at the point $f(a)$. Thus, $\arg \nu_f (b) - 2\pi f^{-1}(b)$, as a function of $b \in \Gamma$, has a finite Dirichlet energy inside $\Omega$. Note that in our definition of $\mathcal{G}_{V}$, we require the $\theta = \arg \nu_f - \frac{\pi}{2}$ on the curve $\Gamma$, and it has a finite energy extension inside $\Omega_{\Gamma}$. Such characterization is very similar to the Weil–Petersson curve. The difference is that in our problem $\Gamma$ is not a closed curve and the domain $\Omega_{\Gamma}$ is not a quasicircle.

In a recent work [5], Christopher Bishop gives 26 equivalent characterizations of the Weil–Petersson class. In particular, he shows that a curve $\Gamma$ is Weil–Petersson if and only if it has arc-length parameterization in $H^{3/2}(\mathbb{T})$, has finite Möbius energy or can be well approximated by polygons in some precise sense. Another equivalent characterization is that Weil–Petersson curve has local curvature that is square integrable over all locations and scales, where local curvatures are measured.
using various quantities such as Peter Jone’s $\beta$-numbers, conformal welding and Menger curvature. We will show that some of these function theoretic and geometric characterizations can be generalized to our curve $\Gamma \in \mathcal{G}_V$, which greatly deepen our understanding of the class $\mathcal{G}_V$. The proofs will follow Bishop’s paper [5] closely, with some necessary modifications.

Given $\Gamma \in \mathcal{G}_V$, we denote the length of $\Gamma$ by $l$. Let $z(t) = (x(t), y(t)) : [0, l] \to \Gamma$ be the arc-length parameterization of $\Gamma$, that is, $\sqrt{x'(t)^2 + y'(t)^2} = 1$ almost everywhere. Then $\Gamma$ has the following properties:

**Proposition 2.7.** 1. The arc-length parameterization $z(t) : [0, l] \to \Gamma$ is in the Sobolev space $H^{3/2}([0, l])$.

2. Let $v$ be the normal vector, it holds that

$$\int_{\Gamma} \int_{\Gamma} \left( \frac{|v(z) - v(w)|}{|z-w|} \right)^2 |dz||dw| < \infty,$$

where $|dz|, |dw|$ denote the element of arc length in the line integral on $\Gamma$.

**Proof.** (1) As in the proof of Lemma 2.3, we construct a quasidisk $D_{\Gamma}$ which is the combination of $\Omega_{\Gamma}$ and a rectangle with length $2a$ and width $a$

$$D_{\Gamma} = \Omega_{\Gamma} \cup \{(x, y) : -a < x < a, -a < y \leq 0\}.$$

The length of $\partial D_{\Gamma}$ is $l + 4a$. We denote the arc-length between $z \in \Gamma$ and $(-a, 0)$ as $l(z)$. Define the function $\phi : \mathbb{T} \to \mathbb{T}$ as

$$\phi(\theta) = \begin{cases} \arg v((l + 4a)\theta)), & 0 \leq \theta \leq \frac{l}{l+4a}, \\ \frac{\pi}{2}, & \frac{l}{l+4a} < \theta < 1. \end{cases} \tag{2.34}$$

One can easily check that in order to show $z \in H^{3/2}([0, l])$, it suffices to show $\phi \in H^{1/2}(\mathbb{T})$. We also define an orientation preserving arc-length parameterization $w : \mathbb{T} \to \partial D_{\Gamma}$, such that $|w'| = l + 4a$, $w(0) = (-a, 0)$ and $w(\theta) = z((l + 4a)\theta)$ for $\theta \in [0, \frac{l}{l+4a}]$. Since $D_{\Gamma}$ is a quasidisk, we can find a map $f$ that is conformal in $D_{\Gamma}$ and can be extended to a quasiconformal mapping in the entire plane. Then on the boundary, $f$ maps $\mathbb{T}$ to the quasicircle $\partial D_{\Gamma}$.

Let $\phi_f := \phi \circ w^{-1} \circ f$. By the definition of $\mathcal{G}_V$, one has $\phi_f \in H^{1/2}(\mathbb{T})$. The rest of the proof is exactly the same as that of [5, Lemma 8.1]. The idea is to show $f^{-1} \circ w$ is a quasisymmetric map by definition and then use the arguments by BEURLING and AHLFORS [3] that $H^{1/2}$ is invariant under composition with a quasisymmetric homeomorphism of $\mathbb{T}$.

(2) By the $H^{3/2}$ characterization, we know $\int_0^l \int_0^l \left| \frac{z'(t) - z'(s)}{t-s} \right|^2 dsdt < \infty$. Since $\Gamma$ is chord–arc, $\frac{|z(t) - z(s)|}{|t-s|} \in [\frac{1}{C}, 1]$ for some constant $C$. We have

$$\int_{\Gamma} \int_{\Gamma} \left( \frac{|v(z) - v(w)|}{|z-w|} \right)^2 |dz||dw| = \int_0^l \int_0^l \left( \frac{|z'(t) - z'(s)|}{|z(t) - z(s)|} \right)^2 dsdt \lesssim \int_0^l \int_0^l \left( \frac{z'(t) - z'(s)}{t-s} \right)^2 dsdt < \infty.$$
Remark 2.8. A direct consequence of the $H^{3/2}$ characterization is $\Gamma$ has finite Möbius energy, that is,

$$M\ddot{\text{ob}}(\Gamma) = \int_{\Gamma} \int_{\Gamma} \left( \frac{1}{|z - w|^2} - \frac{1}{l(z, w)^2} \right) |dz| |dw| < \infty. \quad (2.35)$$

Here $l(z, w)$ is the length of $\Gamma$ between $z$ and $w$. For the proof, one can refer to the proof of [5, Lemma 9.1]. The brief idea is to show that $M\ddot{\text{ob}}(\Gamma) \simeq \int_{\Gamma} \int_{\Gamma} \frac{|l(z, w) - |z - w||}{|z - w|^3} |dz| |dw|$ and then change the order of integration. Furthermore, since $\Gamma$ is chord–arc, it holds that

$$\frac{1}{|z - w|^2} - \frac{1}{l(z, w)^2} = \left( \frac{l(z, w) + |z - w|}{|z - w|^2} \right) \frac{l(z, w) - |z - w|}{|z - w|^3} \simeq \frac{l(z, w) - |z - w|}{|z - w|^3}.$$

Then (2.35) implies that $\int_{\Gamma} \int_{\Gamma} \frac{l(z, w) - |z - w|}{|z - w|^3} |dz| |dw| < \infty$.

Remark 2.9. Other characterizations of Weil–Petersson curve in [5] include approximation by polygons in a precise sense and the square integrability of $\beta$-numbers. The arguments also work for curves in $\mathcal{G}_V$ and we state them here without proof. Again we consider the arc-length parameterization $z(t) : [0, l] \to \Gamma$. For each $n$, let $z^n_j = z\left(\frac{j}{2^n}\right)$ for $j = 0, 1, \ldots, 2^n$. Then it is obvious that $\{z^n_j\}$ divides $\Gamma$ into $2^n$ intervals with equal length. Let $\Gamma^n$ be the curve that consists of all the line segments $z^n_j z^n_{j+1}$ for $j = 0, \ldots, 2^n - 1$. Then one has

$$\sum_{n=1}^{\infty} 2^n |l(\Gamma) - l(\Gamma^n)| < \infty.$$

Recall one of the equivalent definitions of Peter Jone’s $\beta$-number (see [23]): given a curve $\Gamma$, $x \in \mathbb{R}^2$ and $t > 0$,

$$\beta_\Gamma(x, t) := \inf_L \sup_{z \in B(x, t) \cap \Gamma} \frac{\text{dist}(z, L)}{t},$$

where the infimum is over all lines hitting $B(x, t) \cap \Gamma$. Then, for $\Gamma \in \mathcal{G}_V$, this satisfies

$$\int_{\Gamma} \int_{0}^{\infty} \beta_\Gamma^2(x, t) \frac{dt \, dx}{t^2} < \infty.$$

3. Existence of Minimizers

The primary goal of this section is to establish the existence for Problem 1.5. Before we state the theorem, we need to clarify some basic settings. Throughout this section we assume the volume $V = 1$. We will consider $\Gamma \in \mathcal{G}_1$ such that $E_{\Gamma} \leq M$ for some constant $M > 0$ and $\Gamma$ will only intersects with $x$-axis at two endpoints. As a consequence, $\Gamma$ has all the geometric properties that we have shown in Section 2 (Lemmas 2.2, 2.3, Propositions 2.4, 2.5 and 2.7).
Also we need to discuss different notions of boundary since we will perform integration by parts in $\Omega_G$. In geometric measure theory, there are three different kinds of boundary for a set $E$ of finite perimeter: topological boundary $\partial E$, measure-theoretical boundary $\partial^e E$ and reduced boundary $\partial^* E$. We refer to [14] for detailed definitions of these notions. It is well known that $\partial^* E \subset \partial^e E \subset \partial E$. For our domain $\Omega_G$, it is obvious that $\partial^* \Omega_G = \Gamma \cup \{(x,0), -a \leq x \leq a\}$. By Lemma 2.2, one can verify that for any $z \in \Gamma \backslash \{(-a,0), (a,0)\}$, we have

$$\liminf_{r \to 0} \frac{|\Omega_G \cap B(z,r)|}{\pi r^2} > 0, \quad \limsup_{r \to 0} \frac{|\Omega_G \cap B(z,r)|}{\pi r^2} < 1$$

This means $z \in \partial^* \Omega_G$, and therefore, $\partial \Omega_G \backslash \partial^* \Omega_G \subset \{(-a,0), (a,0)\}$. As for the relation between measure-theoretical boundary and reduced boundary, a well-known result by Federer says that $\mathcal{H}^1(\partial^e E \backslash \partial^* E) = 0$ (see, for instance, [12, Lemma 1 in Section 5.8]). In the proof below, we do not distinguish these different notions of a boundary when we write boundary integral.

**Theorem 3.1.** There exists a $\Gamma \in \mathcal{G}_1$ minimizing the functional $E(\Gamma)$ defined by (1.8).

**Proof.** Let $\{\Gamma_i\}_{i=1}^\infty$ be a minimizing sequence in $\mathcal{G}_1$.

$$\lim_{i \to \infty} E(\Gamma_i) = M_0 := \inf_{\Gamma \in \mathcal{G}_1} E(\Gamma).$$

Let $\Omega_i, \Theta_i$ denote the corresponding $\Omega_{\Gamma_i}, \Theta_{\Gamma_i}$, respectively. For each $i$, we set $(\pm a_i, 0)$ as the two endpoints of $\Gamma_i$. Because $l(\Gamma_i) \leq M$ for every $i$, we have $a_i < \frac{M}{2}$. Also by Lemma 2.2 and the fact that $|\Theta_i| = 1$ we have $a_i \leq \sqrt{2}$ where $C$ is the constant in (2.9). Now we summarize all the properties (independent of $i$) we need for $\{(\Gamma_i, \Omega_i, \Theta_i, a_i)\}$ before taking a limit.

(a) $\frac{2}{C} \leq a_i \leq \frac{M}{2}, l(\Gamma_i) \leq M$.

(b) $\Omega_i \subset B(0,2M), |\Omega_i| = 1$ and $\partial \Omega_i = \Gamma_i \cup \{x,0): -a_i \leq x \leq a_i\}$.

(c) $\Gamma_i$ can be parameterized by $(x_i(t), y_i(t))$ such that

\begin{align*}
&x_i(0) = -a_i, \quad x_i(l(\Gamma_i)) = a_i, \quad y_i(0) = y_i(l(\Gamma_i)) = 0, \\
x_i'(t) \geq 0, \quad y_i(t) \geq 0, \quad |x_i'(t)|^2 + |y_i'(t)|^2 = 1, \text{ almost everywhere} \\
&\sqrt{|x_i(t + s) - x_i(t)|^2 + |y_i(t + s) - y_i(t)|^2} \geq \frac{s}{C_3} \quad \text{for } t,s > 0, \ t + s < l(\Gamma_i),
\end{align*}

where $C_3$ is the constant in Proposition 2.4.

(d) $\Theta_i$ can be extended to a $H^1$ function on $B(0, 2M)$ such that $\|\Theta_i\|_{H^1(B(0, 2M))} \leq C_5$ for some universal constant $C_5$.

Then we claim that there is a subsequence, still denoted by $\{(\Gamma_i, \Omega_i, \Theta_i, a_i)\}$ that converges in the following sense:

1. $\chi_{\Omega_i} \to \chi_{\Omega}$ weakly in $BV(B(0, 2M))$ and strongly in $L^1(B(0, 2M))$, for some $\Omega$ which is a set of finite perimeter in $B(0, 2M)$ with volume 1.
2. $\Theta_i \rightarrow \Theta$ weakly in $H^1(B(0, 2M))$ and strongly in $L^2(B(0, 2M))$ for some $\Theta \in H^1(B(0, 1))$.
3. $l(\Gamma_i) \rightarrow l$, $a_i \rightarrow a$ for some constant $l > 0$, $a > 0$.
4. $\Gamma_i \rightarrow \Gamma$ in Hausdorff distance for some chord–arc curve $\Gamma$. $\Gamma$ can be parameterized by $x(t)$, $y(t)$ such that

- $x(0) = -a$, $x(l) = a$, $y(0) = y(l) = 0$,
- $x'(t) \geq 0$, $y(t) \geq 0$, $|x'(t)|^2 + |y'(t)|^2 \leq 1$, almost everywhere
- $\sqrt{|x(t+s) - x(t)|^2 + |y(t+s) - y(t)|^2} \geq \frac{s}{C_3}$ for $t, s > 0$, $t + s < l$

5. $\partial^e \Omega \subset \Gamma \cup \{(x, 0) : -a \leq x \leq a\}$, $v \cdot (\cos \Theta, \sin \Theta) = 0$ almost everywhere on $\partial^* \Omega$.

**Proof of the convergence claim.** (1), (2), (3) are straightforward to check. (4) is a direct consequence of Arzela–Ascoli lemma and Property (c) that we list before, we omitted the detail of the proof. So we only prove (5). First we show $\partial^e \Omega \subset \Gamma \cup \{(x, 0) : -a \leq x \leq a\}$. Assume there exists a point $z \in \partial^e \Omega$ such that $z \notin \Gamma \cup \{(x, 0) : -a \leq x \leq a\}$. Then by convergence properties (3) and (4), there exists a $r_0 > 0$ and $n \in \mathbb{N}$ such that

$$B(z, r_0) \cap \partial \Omega_i = \emptyset, \forall i \geq n.$$ 

For any $i \geq n$, we have

$$\frac{|\Omega_i \cap B(z, r)|}{|B(z, r)|} = 0 \text{ or } 1, \text{ for any } r \leq r_0,$$

however, by the convergence property (1), we have that

$$\frac{|\Omega \cap B(z, r)|}{|B(z, r)|} = \lim_{i \rightarrow \infty} \frac{|\Omega_i \cap B(z, r)|}{|B(z, r)|} = 0 \text{ or } 1, \text{ for any } r \leq r_0,$$

which contradicts our assumption that $z \in \partial^e \Omega$. Therefore, we have proved that $\partial^e \Omega \subset \Gamma \cup \{(x, 0) : -a \leq x \leq a\}$.

Now we set

$$\Omega_{in} := \text{the domain enclosed by } \Gamma \text{ and x-axis},$$
$$\Omega_{out} := \mathbb{R}^2 \setminus (\Gamma \cup \{(x, 0) : -a \leq x \leq a\} \cup \Omega_{in}).$$

By similar density argument one can show $\Omega_{in} \subset \Omega^0$ and $\Omega_{out} \subset \Omega^1$, where $\Omega^t$ is defined as $\{z : \lim_{r \rightarrow 0} \frac{|\Omega \cap B(z, r)|}{\pi r^2} = t\}$. After a modification of a measure zero set, we can simply identify $\Omega$ as $\Omega_{in}$. Now we are left to show the second part of (5), which says the tangential anchoring boundary condition still holds for the limit domain. Let $\phi$ be an arbitrary $C^\infty$ function in $\mathbb{R}^2$, we define

$$n_i := (\cos \Theta_i, \sin \Theta_i), \quad n := (\cos \Theta, \sin \Theta), \quad v_i = \text{normal vector on } \partial \Omega_i.$$
Note that here all $n_i$ and $n$ are defined on the larger domain $B(0, 2M)$. We first deduce that

$$\lim_{i \to \infty} \int_{\Omega_i} \text{div} (\phi n_i) \, dx = \int_{\Omega} \text{div} (\phi n) \, dx. \quad (3.36)$$

In fact,

$$\left| \int_{\Omega_i} \text{div} (\phi n_i) \, dx - \int_{\Omega} \text{div} (\phi n) \, dx \right| \leq \int_{\Omega} \left| \text{div} (\phi n - \phi n_i) \right| \, dx + \int_{\Omega \Delta \Omega_i} |\text{div} (\phi n_i)| \, dx.$$

As $i \to \infty$, the first term goes to zero because $n_i$ converges to $n$ weakly in $H^1$; the second term goes to zero since $\Omega_i$ converges to $\Omega$ in $L^1$ and $n_i$ are uniformly bounded in $H^1$. We also have that the following Gauss–Green formula holds:

$$\int_{\Omega_i} \text{div} (\phi n_i) \, dx = \int_{\partial^* \Omega_i} \phi n_i \cdot v_i \, d\mathcal{H}^1, \quad \int_{\Omega} \text{div} (\phi n) \, dx = \int_{\partial^* \Omega} \phi n \cdot v \, d\mathcal{H}^1. \quad (3.37)$$

We want to point out that (3.37) is not trivial here since $\partial \Omega_i$ is not in $C^1$. However, in our problem, it is valid because all $\Omega_i$ and $\Omega$ are Sobolev extension domains and one can define the trace of $H^1$ function on the reduced boundary. We refer to [28, Proposition 3.4.4] or [2, Theorem 3.84] for more details. We may now combine (3.37) with (3.36) and get that

$$0 = \lim_{i \to \infty} \int_{\partial \Omega_i} \phi n_i \cdot v_i \, d\mathcal{H}^1 = \int_{\partial \Omega} \phi n \cdot v \, d\mathcal{H}^1.$$

Thus, the tangential anchoring boundary condition is proved for $\Omega$ and $n$. \hfill \Box

On the boundaries $\partial \Omega_i$ or $\partial \Omega$, we define the tangent vector $\tau_i$, or correspondingly $\tau$, by rotating the normal vector $v_i$ or $v$ by $\frac{\pi}{2}$ clockwise. One can check that

$$n_i = \tau_i \text{ on } \Gamma_i \backslash \{(x, 0) : x \in [-a_i, a_i]\},$$

$$n_i = -\tau_i \text{ on } \{(x, 0) : x \in [-a_i, a_i]\} \backslash \Gamma_i. \ \forall i \in \mathbb{N}$$

Using similar arguments as to those in the proof of tangential anchoring condition above again, we can show that

$$n = \tau \text{ almost everywhere on } \Gamma \backslash \{(x, 0) : x \in [-a, a]\},$$

$$n = -\tau = (1, 0) \text{ almost everywhere on } \{(x, 0) : x \in [-a, a]\} \backslash \Gamma. \quad (3.38)$$

The idea is to carefully choose a cutoff function $\phi$ and calculate $\int_{\partial^* \Omega} \phi n \cdot \tau \, d\mathcal{H}^1$ using Gauss–Green formula. To be more specific, for any point $x \in \Gamma \backslash \{(x, 0) : x \in [-a, a]\}$, and any small radius $r$, we take a nonnegative smooth function $\phi$ such
that $\phi \equiv 1$ in $B_r(x)$ and $\phi \equiv 0$ in $\mathbb{R}^2 \setminus B_{2r}(x)$. Then by calculating $\int_{\partial^* \Omega} \phi n \cdot \tau \, d\mathcal{H}^1$ as in (3.37) and letting $x$ and $r$ vary, one can obtain that $n \cdot \tau \geq 0$ (further implies $n \cdot \nu = 0$) almost everywhere on $\Gamma \setminus \{(x,0) : x \in [-a,a]\}$. The points on $x$-axis can be treated in the same way and we omit the details here. Note that (3.38) is equivalent to our original boundary condition (1.7), therefore we have verified that $\Gamma \in \mathcal{G}_1$ and $\Omega, \Theta$ are just the corresponding $\Omega_{\Gamma}, \Theta_{\Gamma}$.

Finally, by convergence result (1–5) and lower semi-continuity we conclude that

$$\int_{\Omega} |\nabla \Theta|^2 + l(\Gamma) \leq \liminf_{i \to \infty} E(\Gamma_i) = M_0,$$

and by Lemma 2.1, $\Gamma$ would not touch $x$-axis besides two endpoints, so $(\Gamma, \Omega, \Theta)$ is a minimizer of Problem 1.5. The proof is complete.

Next we want to study the behavior of $\Gamma \in \mathcal{G}_1$ near $(-a,0)$ and $(a,0)$. The following lemma indicates that $\Gamma$ and $x$-axis form approximately cusps near two ends. Note that here we do not assume that $\Gamma$ is a minimizer.

**Lemma 3.2.** Let $\Gamma \in \mathcal{G}_1$ satisfy $E(\Gamma) \leq M$. $\Gamma$ only intersects with $x$-axis at $z_1 = (-a,0)$ and $z_2 = (a,0)$. For any $k > 0$, there exists a constant $r$ that depends on $k$ and $\Gamma$ such that

If $z = (x,y) \in \Gamma \cap B(z_1, r)$, then $\frac{y}{x+a} \leq k$,

If $z = (x,y) \in \Gamma \cap B(z_2, r)$, then $\frac{y}{a-x} \leq k$.

**Remark 3.3.** This lemma implies that as $z \in \Gamma$ approaches $z_1$ (or $z_2$), the angle between the ray $z - z_1$ (or $z - z_2$) and $x$-axis converges to 0.

**Proof of Lemma 3.2.** Without loss of generality, we only prove the lemma near $z_1 = (-a,0)$. We argue by contradiction. Assume the Lemma is false, there would be a constant $k > 0$, a sequence of radiuses $\{r_i\}_{i=1}^\infty$ and a sequence of points $\{(x_i, y_i)\}_{i=1}^\infty \subset \Gamma$ such that

$$r_i \to 0, \quad \sqrt{(x_i + a)^2 + y_i^2} = r_i, \quad \frac{y_i}{x_i + a} = k_i \geq k.$$

By Lemma 2.3, we can extend $\Theta$ from $\Omega_{\Gamma}$ to the whole $\mathbb{R}^2$ such that $\|\Theta\|_{H^1(\mathbb{R}^2)} \leq C$. For every $i$, we introduce the following rescaled functions:

$$\Gamma_i := \left\{ \frac{z - z_1}{r_i} : z \in \Gamma \cap B(z_1, r_i) \right\},$$

$$\Omega_i := \left\{ \frac{z - z_1}{r_i} : z \in \Omega_{\Gamma} \cap B(z_1, r_i) \right\},$$

$$\Theta_i(z) := \Theta(z_1 + r_i z) \quad \text{for} \quad z \in B(0,1)$$

One can easily check that the following properties hold:

(a) $l(G_i) \leq C_3$ for the constant $C_3$ from Proposition 2.4.
The proof of the above convergence property is the same as Theorem 3.1. By lower semi-continuity and weak convergence of \( \Theta_i \) in \( H^1(B(0, 1)) \) we have

\[
\int_{B(0, 1)} |\nabla \Theta_i|^2 \, dx \leq \lim_{i \to \infty} \int_{B(0, 1)} |\nabla \Theta_i|^2 \, dx = 0
\]

Therefore, \( \Theta \) is a constant function, which contradicts with (5) since the normal vector of \( \partial \Omega \) obviously cannot be orthogonal to a constant vector by simple geometry. \( \square \)

As for the regularity of \( \Gamma \) away from two endpoints, Proposition 2.5 and Proposition 2.7 tell that \( \nu \) belongs to VMO and \( H^{1/2}([0, l]) \). Unfortunately this is the best regularity result we have now. Here we give the following natural open problems:

1. \( \chi_{\Omega_i} \to \chi_{\Omega} \) weakly in \( BV(B(0, 1)) \) and strongly in \( L^1(B(0, 1)) \), for some \( \Omega \) with the volume lower bound \( |\Omega| \geq C_6 \).
2. \( \Theta_i \to \Theta \) weakly in \( H^1(B(0, 1)) \) and strongly in \( L^2(B(0, 1)) \) for some \( \Theta \in H^1(B(0, 1)) \).
3. \( I_i \to l \) for a constant \( l > 0 \).
4. \( k_i \to k_0 \) for some \( k_0 \in [k, \infty] \).
5. \( I_i \to I^\ast \) in the sense of Hausdorff distance for some chord-arc curve \( I^\ast \). \( I^\ast \)
can be parameterized by \( (x(t), y(t)) \) such that

\[
(x(0), y(0)) = (0, 0),
\]

\[
(x(l), y(l)) = \begin{cases} 
(-\frac{1}{\sqrt{1+k_0^2}}, -\frac{k_0}{\sqrt{1+k_0^2}}), & k_0 \neq +\infty, \\
(0, 1), & k_0 = +\infty.
\end{cases}
\]

\[
x'(t) \geq 0, \quad y(t) \geq 0, \quad \frac{1}{C_3} \leq |x'(t)|^2 + |y'(t)|^2 \leq 1, \quad \text{almost everywhere}
\]

6. \( \partial^c \Omega \subset I^\ast \cup \{(x, 0) : 0 \leq x \leq 1\} \cup \partial B(0, 1), \quad \nu \cdot (\cos \Theta, \sin \Theta) = 0 \) almost everywhere on \( \partial^c \Omega \).

The proof of the above convergence property is the same as Theorem 3.1. By lower semi-continuity and weak convergence of \( \Theta_i \) in \( H^1(B(0, 1)) \) we have

\[
\int_{B(0, 1)} |\nabla \Theta_i|^2 \, dx \leq \lim_{i \to \infty} \int_{B(0, 1)} |\nabla \Theta_i|^2 \, dx = 0
\]

Therefore, \( \Theta \) is a constant function, which contradicts with (5) since the normal vector of \( \partial \Omega \) obviously cannot be orthogonal to a constant vector by simple geometry. \( \square \)
Problem 3.4. Is \( \Gamma \) a \( C^\infty \) curve, or at least \( C^1 \)?

Problem 3.5. Can one write \( \Gamma \) as a curve of function \( f(x) \), such that \( |\frac{df}{dx}| \leq C \) for some constant \( C < \infty \)?

The difficulty in answering these questions is due to the strong nonlocal character of the tangential anchoring boundary condition. It prevents us from modifying \( \Gamma \) locally to obtain an energy competitor and then deduce decay of some energy quantities. Therefore, some new ideas and methods are needed in order to utilize the minimality. We now assume \( \Gamma \) is the graph of function \( f \in C^3([-a, a]) \), and we compute the Euler–Lagrange equation that \( f \) should satisfy.

Let \( \Gamma = \{(x, f(x)) : x \in [-a, a]\} \) such that

\[
f(-a) = f(a) = 0, \quad f(x) > 0 \text{ for } x \in (-a, a), \quad \text{and } \int_{-a}^{a} f(x) \, dx = 1.
\]

We write \( \Omega_{\Gamma} \) as \( \Omega_f \). Then we consider the perturbation of \( f(x) \) and \( \Omega_f \)

\[
f_t(x) = f(x) + tg(x), \quad \Omega_{f_t}(x) = \{(x, y) : x \in [-a, a], \ y \in [0, f(x) + tg(x)]\},
\]

where \( g \in C^\infty_0([-a, a]) \). We denote the domain variation by \( \Phi(t, x) \) such that

\[
\Phi(t, \Omega_f) = \Omega_{f_t}, \quad \Phi(t, (x, y)) = (x, y + \frac{y}{f(x)}tg(x)).
\]

By this definition, we can see that \( \Phi(t) \) satisfies that

\[
\Phi(0) = 1, \quad \xi(x, y) := \Phi'(0) = \lim_{t \to 0^+} \frac{1}{t} (\Phi(t) - I) = (0, \frac{y}{f(x)}g(x)).
\]

\( \Theta(t, z) \) solves the equation

\[
\begin{cases}
-\Delta \Theta(t, z) = 0 & \text{in } \Omega_{f_t}, \\
\Theta(t) = \arctan(f' + tg') & \text{on } \{(x, f_t(x)) : x \in [-a, a]\},
\end{cases}
\]

(3.39)

(3.39)

Here \( z = (x, y) \in \mathbb{R}^2 \) and \( f', g' \) denote the derivatives of functions \( f, g \) with respect to \( x \). The functional becomes

\[
F(f_t) = \int_{-a}^{a} \sqrt{1 + |f'_t(x)|^2} \, dx + \int_{-a}^{a} \int_{0}^{f_t(x)} |\nabla \Theta(t, z)|^2 \, dx \, dy =: F_1(f_t) + F_2(f_t).
\]

Suppose \( t \to \Theta(t) \) has good differentiability properties (denote by \( \Theta' \) its derivative at \( 0 \)). We can differentiate (3.39) inside \( \Omega_f \) and at the boundary, by differentiating the following identity:

For \( z = (x, f(x)), \quad \Theta(t, \Phi(t, z)) = \arctan(f' + tg') \).

We obtain

\[
-\Delta \Theta' = 0 \text{ in } \Omega_f
\]
\[ \Theta'(x, f(x)) + \nabla \Theta(x, f(x)) \cdot \xi = \frac{g'(x)}{1 + |f'(x)|^2} \text{ on } \Gamma \]
\[ \Theta' = 0 \text{ on } \{(x, 0) : x \in [-a, a]\} . \]

Therefore, \( \Theta' \) is the harmonic function with a Dirichlet boundary condition (depending on \( f, g \)). We compute the derivative of \( F(f_t) \) at \( t = 0 \). For the first part, we easily obtain
\[
\frac{d}{dt} F_1 = \int_{-1}^{1} \frac{f'g'}{\sqrt{1 + |f'|^2}} \, dx.
\]

For the second part, we have
\[
\frac{d}{dt} F_2 = \int_{\Omega_f} \left\{ 2 \nabla \Theta' \cdot \nabla \Theta + \text{div}(|\nabla \Theta|^2 \xi) \right\} \, dx \, dy
\]
\[
= \int_{\Gamma} \left\{ 2 \frac{\partial \Theta}{\partial v} \left( \frac{g'}{1 + |f'|^2} - \nabla \Theta \cdot \xi \right) + |\nabla \Theta|^2 (\xi \cdot v) \right\} \, dH^1
\]
\[
= \int_{-a}^{a} \left\{ 2 \frac{\partial \Theta}{\partial v} \frac{g'}{\sqrt{1 + |f'(x)|^2}} - 2(\nabla \Theta \cdot v)
\cdot (\nabla \Theta \cdot \xi) \frac{1}{\sqrt{1 + |f'(x)|^2} + g(x)|\nabla \Theta|^2} \right\} \, dx,
\]

where \( v \) is the normal vector on \( \Gamma \). Here we have used the boundary condition of \( \Theta' \) and integration by parts. Also, we have used the following formula:
\[
\xi(z) = (0, g(x)), \quad v(z) = \frac{(-f'(x), 1)}{\sqrt{1 + |f'(x)|^2}} \quad \text{for } z = (x, f(x)) \in \partial \Omega_f.
\]

Let \( \frac{d}{dt} F(f_t) = 0 \) and take into account the volume constraint, we obtain the following Euler–Lagrange equation
\[
\lambda = -\frac{d}{dx} \left( \frac{f'}{\sqrt{1 + |f'|^2}} \right) - 2 \frac{d}{dx} \left( \frac{\partial \Theta}{\partial v} \frac{1}{\sqrt{1 + |f'(x)|^2}} \right)
- \frac{\partial \Theta}{\partial v} \frac{\partial \Theta}{\partial y} \frac{1}{\sqrt{1 + |f'|^2} + |\nabla \Theta|^2}, \tag{3.40}
\]

where \( \lambda \) is the Lagrange multiplier and the derivative of \( \Theta \) takes value at \( (x, f(x)) \). Note that (3.40) is complicated and contains some highly nonlocal terms, such as the Dirichlet-to-Neumann map \( \frac{\partial \Theta}{\partial v} \). The first part of the equation is the minimal surface equation while the rest comes from the Dirichlet energy with tangential anchoring condition and domain variation. It will be very interesting to study the well-posedness of (3.40) and we believe that the key of solving the regularity problem of \( \Gamma \) is to understand this equation.
4. Large Volume Limit and Small Volume Limit

In this section we study the behavior of the minimizer as the volume \( V \) tends to be extremely large or small. A naive idea is to analyze the functional (1.8) from a scaling point of view. The curve length term is of dimension one while the Dirichlet energy term is of dimension zero. Therefore, when the volume is very large, the first term will be the dominating term and the minimizer is expected to be close to a semicircle (minimizes length of graph under fixed volume constraint). On the other hand, when the volume is very small, the domain is energy preferable to be very thin to avoid large elastic energy. We will present more rigorous analysis in the rest of this section.

4.1. Large volume limit

Since we are only interested in the shape of \( \Gamma \), we will modify Problem 1.5 and restrict \( a = 1 \). First we make the following notations:

\[
\mathcal{G}_V^a := \{ \Gamma \in \mathcal{G}_V : \Gamma \text{ only intersects with x-axis at } (a, 0), (-a, 0) \}, \quad \mathcal{G}_a := \bigcup_{V > 0} \mathcal{G}_V^a.
\]

Then we can write Problem 1.5 as

\[
\min_{a > 0} \min_{\Gamma \in \mathcal{G}_V^a} \left\{ \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy + l(\Gamma) \right\}.
\]

Let \( \bar{x} = \frac{x}{a}, \bar{y} = \frac{y}{a}, \bar{\Theta}(\bar{x}, \bar{y}) = \Theta(ax, ay) \), the minimization problem becomes

\[
\min_{a > 0} \min_{\Gamma \in \mathcal{G}_V^1} \left\{ \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy + a \cdot l(\Gamma) \right\}.
\]

Setting

\[
\tilde{a} = \frac{a}{\sqrt{V}}
\]

(4.41)

leads to

\[
\min_{\tilde{a} > 0} \min_{\Gamma \in \mathcal{G}_V^1} \left\{ \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy + \tilde{a} \sqrt{V} \cdot l(\Gamma) \right\}.
\]

(4.42)

This is equivalent to

\[
\min_{\Gamma \in \mathcal{G}_V^1} \left\{ \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy + \sqrt{V} \frac{l(\Gamma)}{\sqrt{\Omega_{\Gamma}}} \right\}.
\]

(4.43)

When \( V \gg 1 \), we consider the following functional for \( \Gamma \in \mathcal{G}_V^1 \):

\[
E_V(\Gamma) = \frac{1}{\sqrt{V}} \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy + \frac{l(\Gamma)}{\sqrt{\Omega_{\Gamma}}}.
\]
We denote by $\Gamma_V$ the minimizer of functional $E_V(\Gamma)$. As $V \to +\infty$, one expects that $\Gamma_V$ will “converge” in some proper sense to $\Gamma^* := \{(x, \sqrt{1-x^2}) : x \in [-1, 1]\}$, which is well known to minimize the following functional:

$$F(\Gamma) = \frac{l(\Gamma)}{\sqrt{|\Omega_{\Gamma}|}}$$

for $\Gamma \in \mathcal{G}^1$.

We have the following lemma:

**Lemma 4.1.** $\lim_{V \to \infty} E_V(\Gamma_V) = \sqrt{2\pi} = F(\Gamma^*)$

**Proof.** We borrow the idea of “adding two cusps” from [20]. We modify $\Gamma^*$ near $x = -1$ and $x = 1$ by adding two cusps. For $\epsilon << 1$, we define a function $\bar{f}^\epsilon$ as follows:

$$\bar{f}^\epsilon(x) = \begin{cases} \sqrt{1-x^2}, & |x| \leq \sqrt{1-\epsilon^2}, \\ \frac{\epsilon}{1-\epsilon} - \sqrt{\left(\frac{\epsilon}{1-\epsilon}\right)^2 - \left(x + \sqrt{1+\frac{\epsilon}{1-\epsilon}}\right)^2}, & x \in \left(-\sqrt{1+\frac{\epsilon}{1-\epsilon}}, -\sqrt{1-\epsilon^2}\right), \\ \frac{\epsilon}{1-\epsilon} - \sqrt{\left(\frac{\epsilon}{1-\epsilon}\right)^2 - \left(-x + \sqrt{1+\frac{\epsilon}{1-\epsilon}}\right)^2}, & x \in \left(\sqrt{1-\epsilon^2}, \sqrt{1+\frac{\epsilon}{1-\epsilon}}\right). \end{cases}$$

Note that here we change the graph near two endpoints of $\Gamma^*$ into two circular arcs to make sure the derivative of $\bar{f}^\epsilon$ vanishes near two endpoints (See Fig. 3).

Then we set, for any $\epsilon \in (0, \frac{1}{4})$,

$$f^\epsilon(x) = \bar{f}^\epsilon\left(\sqrt{\frac{1+\epsilon}{1-\epsilon} x}\right),$$

$$\Gamma^\epsilon = \{(x, f^\epsilon(x)) : x \in [-1, 1]\},$$

$$\Theta^\epsilon(x, y) = \arctan \frac{d}{dx} f^\epsilon(x) \quad \text{for} \quad (x, y) \in \Gamma^\epsilon$$

$$\Theta^\epsilon(x, y) = \frac{\arctan \frac{d}{dx} f^\epsilon(x)}{f^\epsilon(x)} \cdot y \quad \text{for} \quad (x, y) \in \Omega_{\Gamma^\epsilon}.$$
2. \( \lim_{\varepsilon \to 0} F(\Gamma^\varepsilon) = \sqrt{2\pi} \),

3. \( \int_{\Omega_{\Gamma^\varepsilon}} |\nabla \Theta|^2 \, dxdy = O(\frac{1}{\varepsilon}) \).

For \( V \gg 1 \), we set \( \varepsilon = V^{-\frac{1}{4}} \). Then
\[
\lim_{V \to \infty} E_V(\Gamma_V) \leq \lim_{V \to \infty} E_V(\Gamma^\varepsilon) = \sqrt{2\pi} \leq \lim_{V \to \infty} E_V(\Gamma_V).
\]

\[ \square \]

Remark 4.2. If \( \lim_{v \to \infty} F(\Gamma_V) = \sqrt{2\pi} \), then
\[
\lim_{v \to \infty} |\Omega_{\Gamma_V} \Delta \Omega_{\Gamma^*}| = 0, \quad \lim_{v \to \infty} d_{H}(\Gamma_V, \Gamma^*) = 0,
\]
where \( d_{H} \) is the Hausdorff distance. This is an easy consequence of the stability of isoperimetric inequality (see [17]).

### 4.2. Small volume limit

First we prove the following lemma which provides a rough estimate for the Dirichlet energy when the volume of droplet is sufficiently small:

**Lemma 4.3.** Take \( \varepsilon \ll 1 \), there exist constants \( c \) and \( C \) which are independent of \( \varepsilon \), such that for any \( \Gamma^\varepsilon \in \mathcal{G}^1_\varepsilon \), it holds that
\[
c\varepsilon \leq \int_{\Omega_{\Gamma^\varepsilon}} |\nabla \Theta|^2 \, dxdy \leq C\varepsilon.
\]

**Proof.** Given \( \Gamma^\varepsilon \in \mathcal{G}^1_\varepsilon \), \( \Theta \) is the corresponding angle function. We first estimate the lower bound of energy. We set
\[
\tilde{\Gamma} = \{(x, y) : (x, \varepsilon y) \in \Gamma\}, \quad \tilde{\Theta}(x, y) = \arctan \left( \frac{\tan \Theta(x, \varepsilon y)}{\varepsilon} \right) \quad \text{for} \quad (x, y) \in \Omega_{\tilde{\Gamma}}.
\]

Then we can check that \( |\Omega_{\tilde{\Gamma}}| = 1 \) and \( \tilde{\Theta} \) satisfies the boundary condition (1.7) corresponding to \( \tilde{\Gamma} \). Thus, there exists a constant \( c \) such that
\[
\int_{\Omega_{\tilde{\Gamma}}} |\partial_y \tilde{\Theta}|^2 \, dxdy \geq c \quad (4.44)
\]

Otherwise one can use the similar argument in Section 3 to get a contradiction. On the other hand, by definition of \( \tilde{\Gamma} \) and \( \tilde{\Theta} \) we have
\[
\int_{\Omega_{\tilde{\Gamma}}} |\partial_y \tilde{\Theta}|^2 \, dxdy = \int_{\Omega_{\tilde{\Gamma}}} \frac{|\partial_y \Theta|^2}{\varepsilon \cdot \left( 1 + \left( \frac{\tan \Theta(x, y)}{\varepsilon} \right)^2 \right)^2 \cdot |\cos \Theta(x, y)|^4} \, dxdy \leq \frac{1}{\varepsilon} \int_{\Omega_{\tilde{\Gamma}}} |\partial_y \Theta|^2 \, dxdy. \quad (4.45)
\]
Therefore,
\[
\int_{\Omega_\Gamma} |\nabla \Theta|^2 \, dx \, dy \geq c \varepsilon,
\]
by (4.44) and (4.45). Meanwhile, we can construct a \( \Gamma \in \mathcal{G}_\varepsilon \) such that
\[
\int_{\Omega_\Gamma} |\nabla \Theta|^2 \, dx \, dy \leq C \varepsilon
\]
for some larger constant \( C \). Set
\[
\Gamma = \{(x, f(x)) : x \in [-1, 1], f(x) = \varepsilon^2 (\cos \pi x + 1)\}
\]
\[
\Theta(x, y) = \frac{\arctan f'(x)}{f(x)} y, \quad \text{for } x \in (-1, 1), \ y \in [0, f(x)].
\]
We can directly verify that \( \Gamma \in \mathcal{G}_\varepsilon \) and \( \int_{\Omega_{\Gamma}} |\nabla \Theta|^2 \, dx \, dy \leq C \varepsilon \) for some constant \( C \) independent of \( \varepsilon \). This proves Lemma 4.3. \( \square \)

**Remark 4.4.** Now we consider the minimization problem (4.42) with \( V = \varepsilon^2 \ll 1 \).
We can determine the appropriate order of \( \tilde{\alpha} \) which is defined in (4.41). Assume \( \tilde{\alpha} \sim O(\varepsilon^{-\alpha}) \) for some \( \alpha \in \mathbb{R} \). Then the second term (surface energy term) is of order \( \varepsilon^{1-\alpha} \). For the Dirichlet energy term since \( \Gamma \in \mathcal{G}_{\varepsilon^{2\alpha}} \), by Lemma 4.3 we know it is of order \( \varepsilon^{2\alpha} \). Matching these two terms gives \( \alpha = \frac{1}{3} \). According to the deduction of (4.42) we know that if we do not fix two endpoints of \( \Gamma \), then the energy-minimizing droplet with volume \( \varepsilon^2 \) will be a elongated drop with length of the order \( \varepsilon^{\frac{2}{3}} \) and the total energy is of order \( \varepsilon^{\frac{5}{3}} \).

Next we study the asymptotic shape of the rescaled droplet. For such purpose, we add some extra regularity assumption on the curve \( \Gamma \). Consider a subset of \( \mathcal{G}^1 \), denoted by \( \tilde{\mathcal{G}}^1 \), which consists of all the curves in \( \mathcal{G}^1 \) that are graphs of \( H^2 \) functions,
\[
\tilde{\mathcal{G}}^1 := \{ \Gamma \in \mathcal{G}^1, \ \Gamma = \{(x, f(x))\} \},
\]
where \( f \) satisfies
\[
f \in H^2_0([-1, 1]), \quad f'(\pm 1) = 0, \quad f(x) > 0 \text{ on } (-1, 1).
\]
(4.46)

Given \( \varepsilon \ll 1 \), we define a transformation operator \( \mathcal{T}_\varepsilon \), which compresses \( \Gamma \in \tilde{\mathcal{G}}^1 \) in the vertical direction:
\[
\mathcal{T}_\varepsilon(\Gamma) = \{(x, \varepsilon^2 f(x)) : x \in [-1, 1]\}, \quad \Gamma = \{(x, f(x))\}.
\]
Now after taking \( V = \varepsilon^2 \) in (4.43) and multiplying \( \varepsilon^{-\frac{2}{3}} \), we obtain the functional
\[ E_\varepsilon(f) = E_\varepsilon(\Gamma) \]

\[ = \varepsilon^{-2/3} \int_{\Omega_{\mathcal{T}_\varepsilon(\Gamma)}} \left| \nabla \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 \, dx \, dy + \varepsilon^{1/3} \frac{l(\mathcal{T}_\varepsilon(\Gamma))}{\sqrt{\Omega_{\mathcal{T}_\varepsilon(\Gamma)}}} \]

\[ = \varepsilon^{-2/3} \int_{\Omega_{\mathcal{T}_\varepsilon(\Gamma)}} \left| \nabla \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 \, dx \, dy + \varepsilon^{1/3} \frac{l(\mathcal{T}_\varepsilon(\Gamma))}{\sqrt{\Omega_{\mathcal{T}_\varepsilon(\Gamma)}}} \]

\[ = \varepsilon^{-2/3} \int_{-1}^{1} \int_{-1}^{\varepsilon^2/3} f(x) \left\{ \left| \partial_x \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 + \left| \partial_y \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 \right\} \, dy \, dx \]

\[ + \frac{\int_{-1}^{1} \sqrt{1 + \varepsilon^2} |f'(x)|^2 \, dx}{\sqrt{\int_{-1}^{1} f(x) \, dx}}. \] (4.47)

Then for a sequence of positive numbers \( \varepsilon \to 0 \), we consider the sequence of functionals on \( H^2_0([-1, 1]) \)

\[ E_\varepsilon(f) := \begin{cases} E_\varepsilon(f) \text{ defined in (4.47),} \\ +\infty \end{cases} \quad \text{if} \quad \Gamma = \{ x, f(x) \} \in \mathcal{G}^1. \] (4.48)

We also define the candidate functional \( E_0(f) \) for \( \Gamma \)-convergence as

\[ E_0(f) := \int_{-1}^{1} \frac{|f'(x)|^2}{f(x)} \, dx + \frac{2}{\sqrt{\int_{-1}^{1} f(x) \, dx}}, \quad f \in H^2_0([-1, 1]). \]

For the definition and general properties of \( \Gamma \)-convergence, we refer to the book [7]. We have the following result:

**Proposition 4.5.** As \( \varepsilon \to 0 \), the sequence \( \{ E_\varepsilon \} \) \( \Gamma \)-converges to \( E_0 \) in the \( H^2 \) topology.

**Proof.** First we prove the lower semi-continuity condition, that is, for any \( g \in C^1_0[-1, 1] \) and for any sequence \( \{ g_\varepsilon \} \) in \( C^1_0[-1, 1] \),

\[ g_\varepsilon \to g \text{ in } H^2[-1, 1] \text{ implies } \liminf_{\varepsilon \to 0} E_\varepsilon(g_\varepsilon) \geq E_0(g). \] (4.49)

The case \( \liminf E_\varepsilon(g_\varepsilon) = +\infty \) is trivial. We therefore assume that \( \liminf E_\varepsilon(g_\varepsilon) = C < +\infty \). And by the \( C^1 \) convergence of \( g_\varepsilon \), we also suppose that \( |g_\varepsilon'(x)| \leq c \) for some constant \( c \) holds for any \( \varepsilon > 0 \) and \( x \in [-1, 1] \). Now we examine the first term of \( E_\varepsilon(g_\varepsilon) \) more closely

\[ \varepsilon^{-2/3} \int_{-1}^{1} \int_{0}^{\varepsilon^2/3} g_\varepsilon(x) \left\{ \left| \partial_x \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 + \left| \partial_y \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 \right\} \, dy \, dx \]

\[ > \varepsilon^{-2/3} \int_{-1}^{1} \int_{0}^{\varepsilon^2/3} g_\varepsilon(x) \left\{ \left| \partial_y \Theta_{\mathcal{T}_\varepsilon(\Gamma)} \right|^2 \right\} \, dy \, dx \]
\[
\geq \varepsilon^{-\frac{2}{3}} \int_{-1}^{1} \frac{|\Theta \mathcal{F}(r) (x, \varepsilon^{\frac{2}{3}} g_{\varepsilon}(x))|}{\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x)} \, dx
\]
\[
= \varepsilon^{-\frac{2}{3}} \int_{-1}^{1} \frac{\|\arctan (\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x))\|}{\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x)} \, dx.
\]

Since \(|g_{\varepsilon}(x)| \leq c\), we have that for any \(\sigma > 0\), there exists \(\varepsilon_{\sigma} > 0\) such that for any \(\varepsilon < \varepsilon_{\sigma}\), \(\|\arctan (\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x))\| \geq (1 - \sigma) \|\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x)\|\). Therefore, we have

\[
\geq \varepsilon^{-\frac{2}{3}} (1 - \sigma)^2 \int_{-1}^{1} \frac{\varepsilon^{\frac{2}{3}} |g_{\varepsilon}(x)|}{\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x)} \, dx = (1 - \sigma)^2 \int_{-1}^{1} \frac{|g_{\varepsilon}(x)|}{g_{\varepsilon}(x)} \, dx, \quad \text{when } \varepsilon < \varepsilon_{\sigma}.
\]

We obtain

\[
\liminf_{\varepsilon \to 0} E_{\varepsilon} (g_{\varepsilon})
= \liminf_{\varepsilon \to 0} \left\{ \varepsilon^{-\frac{2}{3}} \int_{-1}^{1} \int_{0}^{\varepsilon^{\frac{2}{3}} g_{\varepsilon}(x)} \left\{ |\partial_{x} \Theta \mathcal{F}(r)|^2 + |\partial_{y} \Theta \mathcal{F}(r)|^2 \right\} \, dy \, dx \right. \\
+ \left. \frac{\int_{-1}^{1} \sqrt{1 + \varepsilon^{\frac{2}{3}} |g_{\varepsilon}(x)|^2} \, dx}{\sqrt{\int_{-1}^{1} g_{\varepsilon}(x) \, dx}} \right\}
\geq \liminf_{\varepsilon \to 0} \left\{ \int_{-1}^{1} \frac{|g_{\varepsilon}(x)|^2}{g_{\varepsilon}(x)} \, dx + \frac{2}{\sqrt{\int_{-1}^{1} g_{\varepsilon}(x) \, dx}} \right\} \geq E_{0} (g).
\]

Here, in the last step, we used the \(C^1\) convergence of \(g_{\varepsilon}\) and Fatou’s lemma. This gives the proof of the lower semi-continuity (4.49).

The second part of proving Gamma-convergence is to find a recovery sequence for each \(f\) satisfying (4.46). We can simply take \(f_{\varepsilon} = f\) for any \(\varepsilon > 0\). By the same argument in the proof of the lower semi-continuity, we have

\[
\lim_{\varepsilon \to 0} E_{\varepsilon} (f) \geq E_{0} (f).
\]

On the other hand, take \(\Theta_{\varepsilon}(x, y) = \frac{y}{\varepsilon^{\frac{2}{3}} f(x)} \arctan (\varepsilon^{\frac{2}{3}} f'(x))\) for \((x, y)\) satisfying

\(-1 \leq x \leq 1, \ 0 \leq y \leq \varepsilon^{\frac{2}{3}} f(x)\). It holds that

\[
\varepsilon^{-\frac{2}{3}} \int_{-1}^{1} \int_{0}^{\varepsilon^{\frac{2}{3}} f(x)} |\partial_{x} \Theta_{\varepsilon}|^2 \, dy \, dx
= \int_{-1}^{1} \frac{\varepsilon^{\frac{4}{3}} f(x)^3}{3} \left| \frac{f''}{f (1 + \varepsilon^{\frac{2}{3}} f'|^2)} - \frac{f' \arctan (\varepsilon^{\frac{2}{3}} f')}{\varepsilon^{\frac{2}{3}} f^2} \right|^2 \, dx
\]
\[ \sim O(\varepsilon^{\frac{4}{3}}). \]
\[ \varepsilon^{-\frac{2}{3}} \int_{-1}^{1} \int_{0}^{\varepsilon^2 f(x)} |\nabla \theta_\varepsilon|^2 \, dy \, dx \]
\[ = \int_{-1}^{1} \frac{|\arctan(\varepsilon^2 f')|^2}{\varepsilon^{\frac{4}{3}} f} \, dx \sim O(1). \]

After comparing the above two identities, we conclude that
\[ \varepsilon^{-\frac{2}{3}} \int_{-1}^{1} \int_{0}^{\varepsilon^2 f(x)} |\nabla \theta_\varepsilon|^2 \, dy \, dx + \frac{\int_{-1}^{1} \sqrt{1 + \varepsilon^{\frac{4}{3}} |f'(x)|^2} \, dx}{\sqrt{\int_{-1}^{1} f(x) \, dx}} \]
\[ = (1 + o(1)) \int_{-1}^{1} \frac{f''(x)^2}{f} \, dx + \frac{2}{\sqrt{\int_{-1}^{1} f(x) \, dx}} + o(1) = E_0(f) + o(1). \]

Therefore, we obtain \( \lim_{\varepsilon \to 0} E_\varepsilon(f) = E_0(f) \) for any \( f \in H^2_0([-1, 1]) \). The proof is complete.

Proposition 4.5 inspires us to study the following minimization problem:

\[ \min_{g \in H^2_0([-1, 1])} \left\{ \frac{2}{\sqrt{\int_{-1}^{1} g(x) \, dx}} + \int_{-1}^{1} \frac{|g'(x)|^2}{g(x)} \, dx \right\}. \quad (4.50) \]

Letting \( g = h^2 \), the problem becomes

\[ \min_{h^2 \in H^2_0([-1, 1])} \left\{ \frac{2}{\sqrt{\int_{-1}^{1} h(x)^2 \, dx}} + 4 \int_{-1}^{1} |h'(x)|^2 \, dx \right\}. \quad (4.51) \]

The Euler Lagrange equation is

\[ h''(x) = -\frac{h(x)}{4(\int_{-1}^{1} h^2(x) \, dx)^{\frac{1}{2}}}, \quad h \in H^2_0([-1, 1]). \]

This ODE can be solved explicitly as

\[ h(x) = \pi^{-\frac{2}{3}} \cos \frac{\pi}{2} x, \]

and therefore,

\[ g(x) = \pi^{-\frac{4}{3}} \left( \frac{1 + \cos \frac{\pi x}{2}}{2} \right) \]

is the minimizer for the minimization problem (4.50). Using the above \( \Gamma \) -convergence result, we conclude that when \( \varepsilon \) have the volume \( V = \varepsilon^2 << 1 \), the approximated profile of \( \Gamma \) is
The Two-Dimensional Liquid Crystal Droplet

\[ \left\{ \left(x, \varepsilon^{\frac{4}{3}} \pi^{-\frac{2}{3}} \left( 1 + \cos \left( \varepsilon^{-\frac{2}{3}} \pi^{\frac{1}{3}} x \right) \right) \right) : x \in [ -\varepsilon^{\frac{2}{3}} \pi^{\frac{2}{3}}, \varepsilon^{\frac{2}{3}} \pi^{\frac{2}{3}} ] \right\}. \]
