Flexible chiral pyrazolate-based metal–organic framework containing saddle-type Cu\textsuperscript{4}(pyrazolate)\textsubscript{4} units\textsuperscript{†}

Maciej Grzywa, Dmytro Denysenko, Andreas Schaller, Andreas Kalytta-Mewes and Dirk Volkmer*

The syntheses and crystal structures of [CuI\textsubscript{2}(phbpz)].MeOH (lp-CFA-9, lp = large-pore) and [CuI\textsubscript{2}(phbpz)] (np-CFA-9, np = narrow-pore; H\textsubscript{2}-phbpz = 3,3′,5,5′-tetraphenyl-1H,1′H-4,4′-bipryrazole) are described. The copper(i)-containing metal–organic framework (termed Coordination Framework Augsburg University-9, lp-CFA-9) crystallizes in the trigonal crystal system, within the chiral space group P\textsubscript{3}2\textsubscript{1}2\textsubscript{1} (no. 154) and with the following unit cell parameters: a = 18.2348(6), c = 16.3950(4) Å, and \( V \) = 4721.1(2) Å\textsuperscript{3}. lp-CFA-9 features a 3-D microporous framework structure of Cu_{4}pz_{4} (pz = pyrazolate) SBUs with the \( D_{3d} \) (\( \approx 42m \)) symmetry connected by single bonds creating one-dimensional channels expanding in the \( c \)-direction of the crystal lattice. The framework flexibility of CFA-9 has been demonstrated by single-crystal and powder X-ray analyses as well as by sorption measurements. CFA-9 exhibits weak binding of carbon monoxide on Cu(i) centers. The reactivity of CFA-9 towards oxidizing agents, such as H\textsubscript{2}O\textsubscript{2}, t-BuOOH and Br\textsubscript{2} was also investigated. Additionally, CFA-9 shows luminescence upon exposure to UV radiation.

On the other hand, copper-based MOFs have attracted particular interest, which relates to the role of copper centers in the active sites of metalloenzymes, such as oxidases or oxygenases.\textsuperscript{16} Biologically inspired MOF catalysts hold great promise for a wide range of synthetic applications in the oxidation of organic intermediates containing non-activated C–H bonds. Few reports on applications of Cu-MOFs as oxidation catalysts have appeared in the literature. In particular, Cu-catalyzed hydroxylation of phenol,\textsuperscript{17} oxidation of trimethylsilyl enolates to \( \alpha \)-hydroxyketones,\textsuperscript{18} allylic oxidation of cyclohexene,\textsuperscript{19} cross-dehydrogenative coupling reactions of ethers with 2-carbonyl-substituted phenols,\textsuperscript{20} oxidation of benzene derivatives and benzylic compounds\textsuperscript{21} and arylation of heteroarenes\textsuperscript{22} have been described.

Moreover, poly(azololate)-based MOFs (pyrazolate, imidazolate, triazolate, and tetrazolate) are often characterized by superior chemical and thermal stability as compared to their widespread carboxylate-based counterparts, the latter often exhibiting low stability against acidic or basic media and moisture.\textsuperscript{23} As part of our long-term research on functional Cu-MOFs, we have previously described the catalytic activity of CFA-5...
(a Cu(n)-containing MOF) in the aerobic oxidation of tetralin\textsuperscript{24} and the reactivity of Cu\textsuperscript{I}-MFU-\textit{A} towards \textit{C}_{8}H_{8} and CO.\textsuperscript{25} Cu\textsuperscript{I}-MFU-\textit{A} contains highly reactive, coordinatively unsaturated (= “open”) Cu(i)-metal sites, showing fully reversible chemisorption of small molecules such as O\textsubscript{2}, N\textsubscript{2} or H\textsubscript{2} with high isosteric heats of adsorption. Our former studies on the reactivity of a Cu(i)-containing MOF CFA-2 toward molecular oxygen have shown that this compound is stable during the oxidation and reduction of the Cu ions, suggesting its potential usage in liquid-phase oxidation reactions.\textsuperscript{26}

Here, we report on the synthesis and characterization of a new Cu(i)-MOF, termed CFA-9 (Coordination Framework Augsburg University-9), featuring a flexible 3-D microporous framework structure of \textit{Cu}_{4}pz\textsubscript{4} (pz = pyrazolate) SBUs connected to each other by single bonds (Scheme 1). The \textit{Cu}_{4}pz\textsubscript{4} structure motif is rather uncommon and only a few examples of crystalline compounds containing a \textit{Cu}_{4}pz\textsubscript{4} unit can be found in the literature, e.g. a discrete metal complex [\textit{Cu}_{4}(HL\textsubscript{2})\textsubscript{2}] ([H\textsubscript{2}L\textsuperscript{2} = 1,3,5-tris[(3,5-diphenyl-1H-pyrazol-4-yl)methyl]benzene]\textsuperscript{27} and a metal-organic framework \textit{Cu}_{4}L\textsubscript{2} (L = 3,3',5,5'-tetraethyl-4,4'-bipyrazolate)\textsuperscript{28} including two types of SBUs, namely, triangular \textit{Cu}_{3}pz\textsubscript{3} units and saddle-type \textit{Cu}_{4}pz\textsubscript{4} units.\textsuperscript{28} The flexibility of the CFA-9 framework is demonstrated by single-crystal and powder X-ray analyses as well as by gas sorption measurements. CFA-9 is characterized by elemental and thermogravimetric analyses, variable temperature powder X-ray diffraction, and IR and luminescence spectroscopy. Additionally, the reactivity of CFA-9 towards oxidizing agents, such as H\textsubscript{2}O\textsubscript{2}, t-BuOOH and Br\textsubscript{2} is reported.

**Results and discussion**

**Syntheses and characterization**

The 3,3',5,5'-tetraphenyl-1\textsuperscript{H},1'H-4,4'-bipyrazole ligand (H\textsubscript{2}-phbpz) was synthesized according to a modified published procedure.\textsuperscript{26,29} \textit{Lp-CFA-9} was synthesized by a solvothermal reaction starting from a Cu(i)-salt Cu(OAc)\textsubscript{2}-H\textsubscript{2}O and a 3,3',5,5'-tetraphenyl-1\textit{H},1'H-4,4'-bipyrazole ligand in a MeOH/2,6-lutidine system, giving colourless hexagonal prismatic crystals (Fig. 1).

Interestingly, slight changes of reaction conditions (a mixed-solvent system \textit{N},\textit{N}-diethylformamide/EtOH/Et\textsubscript{3}N was used instead of the aforementioned solvent) results in the formation of the Cu(i)-MOF CFA-2 (Scheme 1). CFA-2, featuring a 3-D three-connected two-fold interpenetrated porous structure constructed of triangular Cu(i) subunits and 3,3',5,5'-tetraphenyl-1\textit{H},1'H-4,4'-bipyrazole (phbpz) ligands, exhibits a pronounced breathing effect upon exposure to different guest molecules.

Additionally, applying microwave irradiation in the synthesis of CFA-9, instead of conventional heating, allowed us to reduce the reaction time drastically, from 3 d to 25 min.

**Single crystal structure analysis**

\textit{[CuI\textsubscript{4}(phbpz)]·MeOH (lp-CFA-9)}. \textit{lp-CFA-9} crystallizes in the trigonal crystal system within the chiral space group \textit{P}\textsubscript{3}\textsubscript{1} (no. 154). The asymmetric unit consists of three copper, four nitrogen, thirteen carbon and twenty hydrogen atoms. An Ortep-style plot of the asymmetric unit of \textit{lp-CFA-9} is shown in the ESI,† Fig. S1. \textit{lp-CFA-9} features a 3-D non-interpenetrated microporous structure constructed from \textit{Cu}_{4}pz\textsubscript{4} secondary building units with the \textit{D}_{2d} (= 4\textit{m}\textsubscript{2}) symmetry, each containing a tetranuclear coordination unit of four Cu(i) ions and four pyrazolate ligands, as shown in Fig. 2a and b. The Cu(i) ions within each SBU are two-fold coordinated in a nearly linear arrangement by pyrazolate N-donor atoms from the ligand molecules; the N-Cu-N dihedral angles, therefore, are close to 180° (171.6(3), 172.9(2), 177.7(3)\textdegree). The four central Cu(i) ions are in the same plane, whereas two phbpz\textsuperscript{2-} ligands are positioned above and below this plane, thus building a saddle-shaped structure (see Fig. 2a).

The intramolecular Cu⋯Cu distances range from 3.0252(7) to 3.1829(1) Å. The Cu-N distances range from 1.840(3) to 1.847(3) Å. These values are in good agreement with those found in the structurally related Cu-MOF, \textit{Cu}_{4}L\textsubscript{2} (L = 3,3',5,5'-tetraethyl-4,4'-bipyrazolate),\textsuperscript{28} and copper(i)-containing compounds.\textsuperscript{27} The phenyl groups of each bipyrazole linker are twisted with respect to each other and are disordered.

**Scheme 1** Syntheses of [CuI\textsubscript{4}(phbpz)]·2DEF·MeOH (CFA-2) and [CuI\textsubscript{4}(phbpz)]·MeOH (CFA-9) from the H\textsubscript{2}-phbpz ligand and copper(i) acetate (DEF = \textit{N},\textit{N}-diethylformamide).

**Fig. 1** SEM image (left) and optical micrograph (right) of CFA-9 crystals.
The SBUs of \textit{lp-CFA-9} are connected by single bonds and create one-dimensional channels expanding in the \textit{c}-direction of the crystal lattice (see Fig. 2c and d). Taking the van der Waals radii of hydrogen atoms (1.2 Å) into account, the narrowest channel diameter calculated between the hydrogen atoms of the phenyl groups is 5.96 Å. Estimation using the SQUEEZE\textsuperscript{30} program reveals that the initial solvent accessible void volume is 664.7 Å\textsuperscript{3}, or 0.118 cm\textsuperscript{3} g\textsuperscript{-1}, which is 14.1\% of the unit cell volume (4721.1(2) Å\textsuperscript{3}) for a probe radius of 2.07 Å, corresponding to the approximate van der Waals radius of carbon dioxide.\textsuperscript{31} In the crystal structure of \textit{lp-CFA-9}, the channels are occupied by disordered MeOH molecules. The positions of the solvent molecules were impossible to resolve and refine from the electron density distribution. According to the crystallographic data, there is an electron count of 114 per unit cell, which corresponds to 6.5 MeOH molecules in the unit cell of \textit{lp-CFA-9}. Removal of the solvent by drying and/or heating the sample leads to structural changes. Due to the fact that the \textit{lp-CFA-9} and \textit{np-CFA-9} structures are described in different crystal systems with different space groups which do not have a direct group–subgroup relation between them, the hexagonal unit cell of \textit{lp-CFA-9} was transformed to the orthorhombic one (see Fig. 2c–f). Direct comparison of the unit cells indicates that the structural transition from the solvated sample (\textit{lp-CFA-9}) to a desolvated one (\textit{np-CFA-9}) is connected with the dynamic shortening of the \(a\)- (from 18.23 to 18.09 Å) and \(b\)-lattice parameters (from 31.58 Å to 28.18 Å) and slight elongation of the \(c\)-parameter.
(from 16.40 to 16.72 Å). This process is accompanied by the unit cell volume change from 9442 Å³ (lp-CFA-9) to 8524 Å³ (np-CFA-9). The framework flexibility results from the properties of the tetraphenylbipyrazolate ligand where two pyrazolate rings can rotate around the central C–C single bond. In lp-CFA-9, the angle between the planes created by pyrazolate rings is 60.7°, while in np-CFA-9 the angle value ranges from 65.0 to 65.5° (see Fig. 3). The intramolecular Cu⋯Cu distances in np-CFA-9 range from 3.049(3) to 3.129(1) Å. The Cu–N distances range from 1.774(15) to 1.916(13) Å (see the ESI† Table S1). Taking the van der Waals radii of hydrogen atoms (1.2 Å) into account, the narrowest channel diameter calculated between the hydrogen atoms of the Ph-groups in np-CFA-9 is 4.07 Å, while the smallest aperture of the channel is 2.27 Å. Estimation using the SQUEEZE30 program reveals that the initial solvent accessible void volume is 566.5 Å³, or 0.046 cm³ g⁻¹, which is 6.6% of the unit cell volume (8524.4 Å³) for a probe radius of carbon dioxide.

Topology analysis using the TOPOS program32 (see the ESI†) reveals that the lp-CFA-9 and np-CFA-9 coordination networks can be described as chiral qtz (quartz) nets by regarding the Cu₄pz₄ SBUs as four-connected nodes and the phbpz²⁻ ligands as spacers (see the ESI† and Fig. 4).

The chirality of both networks results from the D₂d symmetry of their SBUs. It is known that α-quartz exists in two crystal structure forms, which represent exact mirror images of each other. Taking into account that these forms are described by two different space groups P3₁21 (no. 152, right-handed screw) and P3₂1 (no. 154, left-handed screw), it can be concluded that lp-CFA-9 described in the P3₂1 (no. 154) space group represents the left-handed screw.33 Due to the fact that in the case of np-CFA-9 two enantiomers can be described in the same P2₁2₁2 (no. 18) space group, the structure of np-CFA-9 was transformed to the P6₃22 (no. 180) and P6₃22 (no. 181) space groups. From the comparison of two structures of lp-CFA-9 P3₂1 (no. 154) and np-CFA-9 P6₃22 (no. 180), it follows that the networks exhibit the same chirality. Interestingly, to the best of our knowledge, only one example of a predicted SiO₂ polymorph described in the P2₁2₁2 (no. 18) space group can be found in the literature.34

The crystal structure transformation from the solvated state to the desolvated one and back upon immersing the dried sample in polar solvents (MeOH, DEF, NMP) is dynamic and reversible, as confirmed by XRPD studies.

TGA and XRPD studies

Microcrystalline powder samples of CFA-9 were exposed to air for a long period of time; the colour change of the sample from white to light green after several months reflects very slow oxidation of the Cu(II) ions. The phase purity of CFA-9 was confirmed by XRPD measurement under ambient conditions. The experimental XRPD pattern of the wet sample (a) is consistent with the simulated one (b), as gleaned from the single crystal X-ray diffraction data, as shown in Fig. 5. Differences in peak intensities

Fig. 3 Structural overlay of the SBUs of lp-CFA-9 and np-CFA-9 (lp-CFA-9 – SBU in black, np-CFA-9 – two different SBUs in red and green).

Fig. 4 (a) Simplified diagram of the SBUs of CFA-9. Topological representation of lp-CFA-9 (b) and np-CFA-9 (c).

Fig. 5 Calculated and measured X-ray powder patterns for CFA-9. (a) Calculated pattern of lp-CFA-9; (b) measured pattern of lp-CFA-9; (c) calculated pattern of np-CFA-9; (d) measured pattern of np-CFA-9; and (e) dried sample re-solvated by DMF.
are due to occluded solvent molecules. Similarly, the experimental XRPD pattern of the dried sample (c) is consistent with the simulated one (d), as gleaned from the single crystal X-ray diffraction data.

In addition, the thermal stability of CFA-9 was determined by thermogravimetric (TG) and VTXRPD measurements. Prior to the measurements, the sample was heated at 100 °C under vacuum for 2 h in order to remove occluded solvent molecules (MeOH). As shown in Fig. 6, the thermogravimetric profile of CFA-9 under nitrogen exhibits a weight loss of 31% between 570 and 650 °C, while under oxygen a weight loss of 73% occurs between 350 and 400 °C. In both cases, the steps are connected with the degradation of the compound. According to the VTXRPD data presented in Fig. 7, the sample is stable up to ca. 450 °C (measurement in a capillary). Above 500 °C, Cu (PDF no. 3-1015) was detected. Removal of the solvent by drying and/or heating the sample leads to XRPD pattern changes, which is connected with the structural changes of the compound. Interestingly, the XRPD pattern of the CFA-9 sample heated at 100 °C for 0.5 h under vacuum can be recovered after the desolvated compound was taken up with polar solvents such as MeOH, EtOH, DMF, DEF or NMP, which indicates that the solvent removal is completely reversible and the initial structure can be recovered (see Fig. 5e).

**Physisorption studies**

The argon adsorption isotherm for CFA-9 measured at 87.3 K (Fig. S4†) is typical of non-porous solids and reveals a BET surface area of only 11 m² g⁻¹. However, the sorption measurement with CO₂ at 194.7 K reveals a much higher BET surface area of 189 m² g⁻¹ and shows a well-pronounced hysteresis in the relative pressure range 0.15–0.3 (Fig. 8), which is typical of breathing MOFs. The pore volume of np-CFA-9 determined from the adsorption branch of the CO₂ isotherm at p/p₀ = 0.1 is 0.051 cm³ g⁻¹ while the volume of lp-CFA-9 determined from the adsorption branch of the CO₂ isotherm at p/p₀ = 0.99 is 0.115 cm³ g⁻¹; both values correspond well to the calculated ones. The flexibility of the framework was additionally investigated by XRPD measurements under CO₂ atmosphere (Fig. 9).

The sample was cooled under vacuum to −78.5 °C and the pressure of CO₂ was gradually increased up to 1000 mbar (red curves in Fig. 9) and then substantially decreased (grey curves). After changing from vacuum to a CO₂ atmosphere, the intensity of the first five Bragg peaks decreased. With

**Fig. 7** VTXRPD plots of CFA-9 kept in air and sampled in a temperature range of 30–550 °C. *Cu PDF no: 3-1015.

**Fig. 8** CO₂ adsorption/desorption isotherms at 194.7 K for CFA-9.

**Fig. 9** XRPD plots of CFA-9 measured at −78.5 °C under vacuum (blue lines) and under increasing CO₂ pressure (red lines) and decreasing CO₂ pressure (grey lines).
increasing CO₂ pressure, new peaks occur (e.g. 9.67° 2θ at 100 mbar, 9.28° 2θ at 500 mbar, and 5.61° 2θ at 600 mbar). Next, decreasing the CO₂ pressure leads to the same XRPD pattern as the one detected under vacuum (blue patterns).

The isosteric heat of CO adsorption determined from adsorption isotherms measured in the temperature range 203–223 K (Fig. S6†) lies at approx. 40 kJ mol⁻¹ at low loading (<0.3 mmol g⁻¹) and decreases to typical physisorption values of 17–20 kJ mol⁻¹ at higher loading (Fig. 10). Such behaviour hints at weak binding of carbon monoxide to Cu(1) centers of CFA-9. Oxygen, in contrast, shows a constant physisorption heat of approx. 15 kJ mol⁻¹ and thus does not bind to the Cu(1) centers.

The adsorption of CO in CFA-9 was further studied by diffuse reflectance Fourier-transform IR spectroscopy (DRIFT). The pre-dried and activated CFA-9 sample was heated to 100 °C under Ar and the atmosphere was changed to CO. The bands at 2170 cm⁻¹ and 2125 cm⁻¹ belong to free CO molecules in the gas phase (black line, Fig. 11). At 100 °C under CO atmosphere, a new band at 2102 cm⁻¹ appeared. Gradually decreasing the temperature in 20 °C steps led to the increase in the intensity of this band until a new weak band at 2050 cm⁻¹ was detected at 40 °C. The corresponding spectra (red lines) are presented in Fig. 11. At ~40 °C, the splitting of the band at 2102 cm⁻¹ was observed and a new additional band centered at 2094 cm⁻¹ was registered. Subsequent lowering of the temperature led to increasing intensities of the bands at 2102 and 2094 cm⁻¹ and the appearance of new bands at 2127 and 2046 cm⁻¹. At ~100 °C, the atmosphere was changed to Ar, and after 1 h the sample was gradually heated up to 100 °C. The corresponding spectra (gray lines) are presented in Fig. 11. With increasing temperature, the bands at 2127, 2094 and 2046 cm⁻¹ gradually decreased in intensity, and at ~40 °C the main bands
at 2102 and 2053 cm$^{-1}$ were observed. Subsequent rising of the temperature led to complete vanishing of these bands at 20 °C. All these recorded bands correspond to the stretch mode of the CO molecule coordinatively bound to Cu$^{2+}$ions and are in good agreement with literature data: $\nu$ CO = 2137 cm$^{-1}$ for [Cu{HB(3,5-(CF$_3$)$_2$pz)$_3$}(CO)]$_3$35 2102 cm$^{-1}$ for [Cu{HB(3-C$_3$F$_7$pz)$_3$}(CO)]$_3$36 2056 cm$^{-1}$ for [Cu{HB(3,5-iPr$_2$pz)$_3$}(CO)]$_3$37 and 2043–2063 cm$^{-1}$ for hemocyanin.38

In order to prove the reactivity of CFA-9 towards oxidizing reagents, the compound was oxidized by H$_2$O$_2$ or t-BuOOH and investigated by UV-vis spectroscopy. The solid-state UV-vis spectrum of CFA-9 displays one strong absorption peak at 318 nm in the UV region, which could be assigned to the intraligand electron transitions (Fig. 12). The UV-vis spectra of CFA-9 samples, oxidized by H$_2$O$_2$ or t-BuOOH, exhibit one additional broad peak with the maximum centered at ca. 600 nm, which encompasses the Cu$^{II}$ d–d transitions.39 The XRPD patterns of the oxidized samples are similar to that of the CFA-9 sample (see Fig. S2†). Furthermore, the oxidized CFA-9 sample can be reduced back to a Cu(I)-MOF upon heating in DMF at 120 ºC for 4 h. The XRPD pattern is also similar to that of the CFA-9 sample, indicating that the structure remains stable during this oxidation/reduction sequence.

X-ray photoelectron spectroscopy (XPS) further proves the redox activity of CFA-9. Fig. 13 depicts the XPS spectrum of CFA-9 oxidized by H$_2$O$_2$, which shows a prominent satellite feature at about 940 eV between the two Cu 2p peaks. This

Table 2 Emission and excitation data for pyrazolato compounds at r.t.
and 931 eV. Peak shape analysis of the Cu2p3/2 peaks of lip-CFA-9 shows only the Cu2p1/2 and Cu2p3/2 peaks at about 951 eV. Applying a higher initial Br2/Cu ratio allows the reactivity of CFA-9 towards Br2 to be investigated. 11.3 mg (0.01 mmol) of the sample was added to solutions of Br2 in CH2Cl2 (0.005, 0.01, 0.015, 0.02 and 0.05 mmol) and stirred for 15 minutes at r. t. The color of the samples changed from colorless to brown. Then, the samples were filtered off by suction, washed thoroughly with MeOH and dried. The samples were analyzed by EDX spectroscopy (Table 1) and X-ray diffraction (Fig. 15). Several attempts were undertaken to perform single-crystal X-ray diffraction measurements. Unfortunately, the quality of the Br2-treated crystals was not sufficient for the measurement. Instead, the samples were investigated by powder X-ray diffraction. The XRD measurements show that the crystallinity of the framework is close to 100%. (2) When a higher Br2/Cu ratio of 0.5 was obtained. Applying a higher initial Br2/Cu ratio allows the increase in the Br/Cu ratio in the product, but also leads to subsequent degradation of the framework.

**Table 3 Crystal data and structure refinements of lip- and np-CFA-9**

| Compound | lip-CFA-9-MeOH | np-CFA-9 |
|----------|----------------|----------|
| **Empirical formula** | C31H24Cu2N4O | C30H20Cu2N4 |
| **Formula** | Cu2C12H20N2O | Cu2C12H20N2 |
| **Mw/g mol⁻¹** | 595.62 | 1953.58 |

Additionally, the reactivity of CFA-9 towards Br2 was investigated. 11.3 mg (0.01 mmol) of the sample was added to solutions of Br2 in CH2Cl2 (0.005, 0.01, 0.015, 0.02 and 0.05 mmol) and stirred for 15 minutes at r. t. The color of the samples changed from colorless to brown. Then, the samples were filtered off by suction, washed thoroughly with MeOH and dried. The samples were analyzed by EDX spectroscopy (Table 1) and X-ray diffraction (Fig. 15). Several attempts were undertaken to perform single-crystal X-ray diffraction measurements. Unfortunately, the quality of the Br2-treated crystals was not sufficient for the measurement. Instead, the samples were investigated by powder X-ray diffraction. The measurements show that the crystallinity of the framework is completely retained only when a 1:1 Br2/Cu ratio was applied. In this case, a product with an approx. Br/Cu ratio of 0.5 was obtained. Applying a higher initial Br2/Cu ratio allows the increase in the Br/Cu ratio in the product, but also leads to subsequent degradation of the framework.

**Photoluminescence**

Pyrazolate-bridged complexes containing Cu(i) ions with d¹⁰ closed-shell electronic configuration are known to show luminescence. Upon irradiation with UV light, Cu(i) pyrazolates undergo a metal-to-ligand charge transfer resulting in a characteristic maximum is only present for Cu(II) species, e.g. Cu(OAc)2. The XPS spectrum of the as-synthesized CFA-9 shows only the Cu2p1/2 and Cu2p3/2 peaks at about 951 eV and 931 eV. Peak shape analysis of the Cu2p3/2 peaks of lip-CFA-9 and oxidized CFA-9 also speaks in favour of Cu(II) for the former and Cu(I) for the latter (see Fig. 14).

Additionally, the reactivity of CFA-9 towards Br2 was investigated. 11.3 mg (0.01 mmol) of the sample was added to solutions of Br2 in CH2Cl2 (0.005, 0.01, 0.015, 0.02 and 0.05 mmol) and stirred for 15 minutes at r.t. The color of the samples changed from colorless to brown. Then, the samples were filtered off by suction, washed thoroughly with MeOH and dried. The samples were analyzed by EDX spectroscopy (Table 1) and X-ray diffraction (Fig. 15). Several attempts were undertaken to perform single-crystal X-ray diffraction measurements. Unfortunately, the quality of the Br2-treated crystals was not sufficient for the measurement. Instead, the samples were investigated by powder X-ray diffraction. The measurements show that the crystallinity of the framework is completely retained only when a 1:1 Br2/Cu ratio was applied. In this case, a product with an approx. Br/Cu ratio of 0.5 was obtained. Applying a higher initial Br2/Cu ratio allows the increase in the Br/Cu ratio in the product, but also leads to subsequent degradation of the framework.

** Photon luminescence**

Pyrazolate-bridged complexes containing Cu(i) ions with d¹⁰ closed-shell electronic configuration are known to show luminescence. Upon irradiation with UV light, Cu(i) pyrazolates undergo a metal-to-ligand charge transfer resulting in a charge separated excited singlet state. This state can either decay to the ground state by emission of slightly red-shifted light, or undergo spin conversion into an excited triplet state, which shows slow decay (luminescence) to the ground state. The latter transition might be influenced by weak Cu⋯Cu interactions that typically occur in Cu(i) complexes and coordination polymers comprising bridging pyrazolate ligands. The usually broad luminescence band for Cu(i) pyrazolates is observed between ca. 460 and 660 nm (see Table 2). CFA-9 irradiated at 312 nm gave two broad emission bands with the maxima at 360 and 660 nm (Fig. 16). The luminescence behaviour of CFA-9 was almost the same as those previously reported in the literature and results from intramolecular Cu⋯Cu interactions (3.049(3) Å intra) and 8.266(2) Å (inter) Cu⋯Cu distances in CFA-9.

**Conclusions**

The work reported here focuses on the synthesis and characterization of a chiral metal–organic framework assembled from tetranuclear Cu(i) secondary building units and 3,3′,5,5′-tetraphenylbipyrazolate ligands. CFA-9 exhibits breathing effects upon exposure to different kinds of polar liquids (MeOH, EtOH, DMF, DEF, NMP), whereas non-polar solvents are not taken up at all. The framework flexibility results from the properties of the tetraphenylbipyrazolate ligand where two pyrazolate rings can rotate around the central C–C single bond. The interplanar angle changes from 60.7° (fully solvated state, lip-CFA-9) to 65.0–65.5° (fully desolvated form, np-CFA-9). The structural dynamics accompanying solvent removal and uptake in CFA-9 are connected with the changes...
of the crystal system from hexagonal to orthorhombic (np-CFA-9 phase) and back to hexagonal (lp-CFA-9 phase), respectively. The weak chemisorption of carbon monoxide on Cu(i) centers was confirmed by sorption and IR measurements, whereas no chemisorption of oxygen was observed. The reactions of CFA-9 with H₂O₂ or t-BuO₂OH indicate that the MOF is stable during repeated oxidation/reduction sequences.

Experimental

Materials and general methods

Commercially available reagents of analytical grade were used as received without further purification.

Synthesis of CFA-9

Solventothermal method. A mixture of Cu(OAc)₂·H₂O (8 mg, 0.04 mmol) and H₂-phpz (30 mg, 0.06 mmol) was dissolved in MeOH (4 mL). 2,6-Dimethylpyridine (2,6-lutidine) (0.05 mL) was added and the solution was placed in a glass tube (10 mL). The tube was closed with a cap and heated at 120 °C for 3 d and then subsequently cooled to room temperature. The colourless crystals were filtered off by suction and washed thoroughly with MeOH. The synthesis can be similarly performed at larger quantities (upscale factor: 50). Yield: 7 mg, 29% (based on Cu(OAc)₂·H₂O). IR: (cm⁻¹) 473 w, 486 w, 503 w, 570 w, 609 w, 649 m, 691 vs, 718 s, 746 s, 756 s, 782 s, 792 w, 837 w, 908 w, 1015 m, 1072 w, 1119 m, 1157 w, 1176 w, 1297 w, 1319 w, 1334 w, 1415 w, 1447 s, 1467 m, 1511 w, 1575 w, 1601 w, 1746 w, 1868 w, 1868 w, 1942 w, 2050 w. The IR spectrum of CFA-9 is shown in Fig. S3.†

Microwave irradiation method. A mixture of Cu(OAc)₂·H₂O (8 mg, 0.04 mmol) and H₂-phpz (30 mg, 0.06 mmol) was dissolved in MeOH (3 mL). 2,6-Dimethylpyridine (2,6-lutidine) (0.05 mL) was added and the solution was placed in a Pyrex sample tube (10 mL). The tube was closed with a cap and placed in a microwave synthesizer (CEM, Discover S). The resulting mixture was heated to 150 °C at 300 W for 25 min and then cooled to room temperature. The colourless microcrystalline material was filtered off by suction and washed thoroughly with MeOH. The synthesis can be similarly performed at larger quantities (upscale factor: 50). Yield: 8 mg, 33% (based on Cu(OAc)₂·H₂O). This material exhibited the same analytical results as the one obtained by the solvothermal method.

Physical methods. Fourier transform infrared (FTIR) spectra were recorded with ATR unit in the range 4000–400 cm⁻¹ on a Bruker Equinox 55 FT-IR spectrometer. The following indicators are used to characterize absorption bands: very strong (vs), strong (s), medium (m), weak (w). Thermogravimetric analysis (TGA) was performed using a TGA Q500 analyzer in the temperature range of 25–800 °C in flowing nitrogen at a heating rate of 10 K min⁻¹. Ar, CO, CO₂ and O₂ sorption isotherms were measured using a BELSORP-MAX instrument combined with a BELCryo system. The amounts of adsorbed gas are given in cm³ g⁻¹ [STP], where STP = 101.3 kPa and 273.15 K. Prior to measurements, the sample was heated at 100 °C for 2 h under high vacuum in order to remove occluded solvent molecules. Ambient temperature X-ray powder diffraction (XRPD) patterns were measured using a Seifert XRD 3003 TT diffractometer equipped with a Meteor 1D detector operated at 40 kV, 40 mA, and CuKα (λ = 1.54247 Å) with a scan speed of 10 s per step and a step size of 0.02° in 2θ. The variable temperature XRPD data were collected in the 2θ range of 5–60° with 0.02° steps, using a Bruker D8 Advance diffractometer equipped with a Lynxeye linear position-sensitive detector, an MRI TCPU1 oven, in transmission geometry. The sample was loaded into a capillary (Hilgenberg) made from special glass no. 10, with 0.5 mm diameter and 0.01 mm wall thickness. The patterns were recorded in a temperature range from 30 to 250 °C, in the 5–60° 2θ range, with one step per 1 s and an angular step width of 0.02° in 2θ. The temperature program between measurements is as follows: a heating rate of 0.5 °C s⁻¹ and then 10 min isothermal. The XRPD data under CO₂ pressure were collected using an Empyrean (PANalytical) Diffractometer equipped with a Bragg-BrentanoHβ mirror, a PICell 3D 2 × 2 detector and a Cryo & humidity Chamber CHC plus (Anton Paar). The sample was cooled under vacuum to −78.5 °C. Next, the pressure of CO₂ was gradually increased up to 1000 mbar and then substantially decreased. The patterns were recorded in the 4–50° 2θ range, with one step per 185.4 s and an angular step width of 0.03° in 2θ. The diffuse reflectance Fourier-transform IR spectra (DRIFT) were collected between 3500–400 cm⁻¹ using an Equinox 55 FT-IR spectrometer equipped with a Praying Mantis diffuse reflectance accessory and an environmental chamber (Harrick Scientific Products) and referenced to KBr. X-ray photoelectron spectra (XPS) were obtained by employing an Omicron spectrometer featuring a monochromatic Mg anode (XM 1000 MK II, 1486.7 eV) and a hemispherical analyzer (EA 125). Each spectrum was collected from 925 to 960 eV with 120 to 160 sweeps. Energy-dispersive X-ray spectroscopy (EDX) was performed using a Philips XL 30 FEG scanning electron microscope equipped with an EDAX SiLi detector. Luminescence spectra were acquired using a spectrofluorimeter (FS920, Edinburgh Instruments) equipped with a TMS300 monochromator, an S900 single photon photomultiplier, and a Xe 900 450 W xenon arc lamp at r.t. The excitation and emission spectra were corrected for the wavelength-dependent lamp intensity and detector response, respectively.

Single-crystal X-ray diffraction. The crystal of lp-CFA-9 was collected from the mother liquor and mounted on a MiTeGen MicroMounts. The sample CFA-9 was dried in air and several crystals of np-CFA-9 were mounted on a MiTeGen MicroMounts and tested using a diffractometer. Unfortunately, most of the crystals scattered only up to 32° 2θ (1.3 Å resolution). Most of the dried crystals were cracked (see the SEM picture, Fig. 1). The best recorded data were obtained for a single crystal of np-CFA-9 with approx. dimensions of 121 × 49 × 66 μm³. X-ray data for the single crystal structure determinations of lp- and np-CFA-9 were collected using a Bruker D8 Venture diffractometer. Intensity measurements were...
performed using monochromated (doubly curved silicon crystal) MoKα radiation (0.71073 Å) from a sealed microfocus tube. The generator settings were 50 kV and 1 mA. The data collection temperature was –173 °C. APEX2 software was used for the preliminary determination of the unit cell. The determination of integrated intensities and unit cell refinement was performed using SAINT. The structures were solved and refined using the Bruker SHELLXTL Software Package. Selected crystal data and details of structure refinements are provided in Table 3.
