A study of non-prescription usage of antibiotics in the upper respiratory tract infections in the urban population

Sir,
In recent years the use and the overuse of antibiotics to treat Upper Respiratory Tract Infections (URTIs) has resulted in the development of resistance patterns across widespread areas. Most URTIs are self-limiting viral infections due to rhinovirus, para-influenza virus, corona virus and adenovirus and resolve without prescription drugs. There is sufficient evidence to support the viral origin of most of these illnesses. However, even some of the bacterial illnesses are also self-limiting and antibiotic treatment is unnecessary. Acute bacterial sinusitis develops in 0.5-2% of cases of viral URTI. Recognizing viral or bacterial diseases (for which specific therapy is available) is important. Therapy addressing specific symptoms is the mainstay for most URTIs (viral). Antibiotics have no role in the management of common cold or any mild URTI except when it is due to bacterial infections like...
Research Letter

stopping taking antibiotics after relief from symptoms and rest after experiencing diarrhoea as a side effect. The chemist’s advice was the most common source of information, taken by patients for the OTC purchase of antibiotics (48%), followed by previous experience. Other sources of information were the relatives and the internet. Most (90%) of the drugs purchased were branded drugs, rest were generic.

The data shows a gross over-usage of non-prescription antibiotics, that too not taken for a full course, by most of the patients of URTI. Taking the drugs for inadequate duration worsens the scenario even more. The study shows the lack of awareness in the patients about the fact that it could increase the drug resistance problem. The study showed that awareness about the branded drugs being costlier than the generic drugs was also not there.

Most of the URTIs are self-limiting viral infections, not requiring the use of antibiotics. Patients need to take rest, adequate amount of fluids, antipyretic drugs and symptomatic treatment for cough and cold to recover from viral URTI. Literature shows that nasal symptoms improve after treatment with β-adrenergic agonists and anti-histamines. Warm saline gargles and steam inhalation are inexpensive and relatively safe measures that provide temporary relief of throat symptoms. Non-steroidal anti-inflammatory drugs are useful for relieving fever, headache and malaise.

The wide-spread use of antibiotics and that too broad spectrum ones results in emergence of many multi-resistant bacteria. In order to preserve the activity of currently available antibiotics for as long as possible, care should be taken about the judicious use of these only in serious infections or the ones that are likely to respond significantly to treatment. The more judicious use of antibiotics can reduce resistance.

Guidelines recommend that patients must visit the prescriber if there are symptoms indicating middle ear infection or acute bacterial sinusitis. These may be nasal discharge, hyposmia

or anosmia, fever, cough, fatigue, maxillary dental pain, ear pressure or fullness. Antibiotics use by the physician should be reserved for moderate symptoms, not improving after 10 days or worsening after 5-7 days.\[^{5,6}\]

This study highlights about the ignorance of even urban, educated patients about the problems associated with misuse of antibiotics. So, advice regarding judicious and rational use of antibiotics must be given by the healthcare professionals, whenever patient approaches them for some reason or through patient information brochures and newsletters.

Patients should be educated about the existence of bacterial and viral infections and also that the antibiotics would be of no use in a viral illness. The fact that these drugs could become ineffective, even for a bacterial infection, if misused or over-used, must be conveyed to them. Patient education can help in reducing the drug resistance problem to a great extent. Drug regulatory authorities must also take adequate steps to curb the OTC availability of antibiotics and empirical use of broad spectrum antibiotics should be curbed in URTIs in the larger interest of the patients.
