This work concerns how to find the double periodic form of approximate solutions of the perturbed combined KdV (CKdV) equation with variable coefficients by using the homotopic mapping method. The obtained solutions may degenerate into the approximate solutions of hyperbolic function form and the approximate solutions of trigonometric function form in the limit cases. Moreover, the first order approximate solutions and the second order approximate solutions of the variable coefficients CKdV equation in perturbation $\varepsilon u$ are also induced.

1. Introduction

To solve the nonlinear partial differential equation (NPDE) has been an attractive research topic for mathematicians and physicists. Nonlinear evolution equations with variable coefficients can describe the physical phenomenon more accurately, and it is of great significance to study how to find the solutions of nonlinear evolution equations with variable coefficients.

In recent years, many researchers have developed various approaches for attaining the exact solutions and approximate solutions of nonlinear partial differential equations such as the inverse scattering method [1], homogeneous balance method [2], elliptic function method [3], and perturbation method [4]. A recently reported analytic approximate method, the homotopic mapping method proposed in [5], has been applied to solve many nonlinear evolution equations with variable coefficients. In this work, we applied the homotopic mapping method to the variable coefficients perturbed CKdV equation and obtained the approximate solution of the Jacobi elliptic function form.

2. Model and Homotopy Mapping

In this work, we focus on the perturbed CKdV equation with variable coefficients

$$ u_t + a(t) uu_x + b(t) u^2 u_x + c(t) u_{3x} = f(x, t, u, u_x, u_t), $$

(1)

where $a(t), b(t), c(t)$ is any function about $t$, $f$ is a disturbance term, and $f$ is the sufficiently smooth function. This equation is widely used in the field of plasma physics [13], fluid mechanics [14], and quantum field theory [15]. It is fascinating to observe that when $a(t), b(t), c(t)$ is constant, $f = 0$, (1) becomes the well-known combined KdV equation, the equation in plasma physics which describes the acoustic wave propagation of a small-amplitude ion without Landau decay. It can be used as a model equation in fluid mechanics; related research can be referred to in [16, 17].

When $f = R(t)$, (1) becomes the forced combined KdV equation, and the exact solutions of various forms are given in [18, 19], such as solitary wave solutions, trigonometric function solutions, and Jacobian elliptic function solutions. When $b(t) = 0$, [20] studied the elliptic function solution of composite form.
Next, we study the approximate solution of (1). In order to simplify (1), set

\[ x' = \sqrt{\frac{c_1 a(t)}{c_1(t)}} x, \quad t' = \int_0^t \sqrt{\frac{c_2 a^3(r)}{c_1(t)}} dr, \]

(2)

where \( c_1, c_3 \) are any constants.

By setting \( c_2(t) = b(t) c_1(t) \), (1) can be expressed as

\[ u_t + c_1 u_{uu} + c_2(t) u^2 u_x + c_3 u_{3x} = f^* (x', t', u, u_x, u_{xx}), \]

(3)

where

\[ f^* (x', t', u, u_x, u_{xx}) = \left( f \left( \sqrt{\frac{c_1(t)}{c_1(t)}} x', t', u, u_x, u_{xx} \right) - \frac{b(t)}{c_2(t)} \sqrt{\frac{c_2 a^3(t)}{c_1(t)}} \right) \left( t' \right)^{-1}. \]

For the sake of convenience, let \( x = x', t = t', f(x, t, u, u_x, u_{xx}, u_{xxx}) = f^* (x', t', u, u_x, u_{xx}), \) and (3) can be written as

\[ u_t + c_1 uu_x + c_3 u_{3x} = -c_2(t) u^2 u_x + f(x, t, u, u_x, u_{xx}); \]

(5)

the study on the solution of (1) is translated into the solution of (5).

In order to get the solution of (1), we lead in homotopy mapping.

### 2.1. Introduction of Homotopy Mapping

Assume we are given nonlinear equation \( A(u) - f(r) = 0, r \in \Omega \) and boundary condition \( B(u, \partial u/\partial n) = 0, r \in \Gamma \), where \( A \) is the general differential operator, \( B \) is the boundary operator, \( f(r) \) is the known analytic function, and \( \Gamma \) is the boundary of the region \( \Omega \). Generally speaking, the operator \( A \) can be decomposed into linear part \( L \) and nonlinear part \( N \). So equation \( A(u) - f(r) = 0 \) can be written as \( L(u) + N(u) - f(r) = 0 \).

Now we set up homotopy mapping: \( H(u, p) : \Omega \times [0, 1] \rightarrow \mathbb{R}, \)

\[ H(u, p) = L(u) - L(v) + p (L(v) + N(u) - f(r)), \]

(6)

where \( p \) is parameter, \( v \) is auxiliary function, and \( L(v) + N(v) = 0 \).

By (6), we obtain

\[ H(u, 0) = L(u) - L(v), \]

\[ H(u, 1) = A(u) - f(r) = 0. \]

(7)

As can be seen from 0 to 1 of \( p \) is the process of \( L(u) - L(v) \) to \( A(u) - f(r) \) of \( H(u, p) \); this is the homotopy deformation. Set

\[ \tilde{u}(x, t, p) = \sum_{i=0}^{\infty} u_i (x, t) p^i = u_0 + pu_1 + p^2 u_2 + \cdots \]

(8)

is the solution of \( H(u, p) = 0 \). So when \( p = 0, \tilde{u}(x, t, 0) = u_0(x, t) \) is the solution of \( L(u) - L(v) = 0 \); when \( p \rightarrow 1 \), the approximate solution of \( A(u) - f(r) = 0 \) is \( u(x, t) = u_0 + u_1 + u_2 + \cdots \).

### 2.2. Approximate Solution of the Jacobi Elliptic Function Form

Aiming at (5), we set up homotopy mapping \( H(u, p) : \mathbb{R} \times I \rightarrow \mathbb{R}, \)

\[ H(u, p) = L(u) - L(v) + p (L(v) + c_1 uu_x + c_2(t) u^2 u_x - f(x, t, u, u_x, u_{xx})) \]

(9)

has the following elliptic function solution:

\[ v_1 = c_1 v_{xx} + c_2 v_{3x} = 0 \]

(10)

When \( m \rightarrow 1, v_1(x, t) \) degenerates to the following solitary wave solution:

\[ v_{1,1} (x, t) = c_0 + \frac{-6k^2 c_3 m^2 sn(\xi, m) + 12k^2 c_3 (m^2 - 1) cn(\xi, m)}{c_1 (sn(\xi, m) + cn(\xi, m) + dn(\xi, m))}, \]

(12)

When \( m \rightarrow 0, v_1(x, t) \) degenerates to the trigonometric function solution

\[ v_{1,2} (x, t) = c_0 + \frac{12k^2 c_3 \cos \xi}{c_1 (\sin \xi + \cos \xi + 1)} \]

(13)

where \( \xi = kx + \left[ -c_0 k c_1 + k^2 c_1 (4m^2 - 5)t \right] t + \xi_0, k, c_0, \xi_0 \) is any constant, \( m \) is the module, and \( 0 \leq m \leq 1 \).

One can easily prove that \( H(u, 1) = 0 \) and (5) is the same, so the solution \( u(x, t) \) of (5) is the solution of \( H(u, p) = 0 \) when under the condition \( p \rightarrow 1 \).
Let
\[
\tilde{u}(x, t, p) = \sum_{i=0}^{\infty} u_i(x, t) p^i = u_0 + pu_1 + p^2u_2 + \cdots \tag{14}
\]
be the solution of \(H(u, p) = 0\); by [22] we can know this series is uniformly convergent in the \(p \in [0, 1]\). Thus, it yields that
\[
u = \sum_{i=0}^{\infty} u_i(x, t) = u_0 + u_1 + u_2 + \cdots \tag{15}
\]

3. Approximate Solution

In order to obtain the approximate solution of (5), we substitute (14) into equation \(H(u, p) = 0\). By taking the auxiliary function \(v = v_i(x, t)\) and comparing the coefficients of the same power of \(p\), one can obtain that
\[
p^0 : L(u_0) = L(v) = L(v_i), \tag{16}
\]
\[
p^1 : L(u_1) = -L(v_i) - c_1u_0u_{0x} - c_2(t) u_0^2u_{0x} + f(x, t, u_0, u_{0x}, u_{0xx}), \tag{17}
\]
\[
p^2 : L(u_2) = -c_1u_0u_{1x} - c_1u_1u_{0x} - c_2(t) u_0^2u_{1x} + F(u_0, u_1), \tag{18}
\]
where \(F(u_0, u_1) = (\partial/\partial p)f(x, t, u, \bar{u}, u_x, u_t)\) at \(p = 0\).

From (16) we have
\[
u_0(x, t) = v_1(x, t). \tag{19}
\]
By using the Fourier transform, one can obtain the solution of (17) with the initial condition \(u_1|_{t=0} = 0\) as follows:
\[
u_1(x, t) \tag{20}
\]
Similarly, one also finds the solution of (18) with the initial condition \(u_2|_{t=0} = 0\)
\[
u_2(x, t) \tag{21}
\]
From (11), (12), (13), (20), and (21), the two degree approximate solutions of (5) can be obtained
\[
u_2^*(x, t) \tag{22}
\]
where \(\xi = kx + [-c_0k\xi + k^2c_3(4m^2 - 5)]t + \xi_0; k, c_0, \xi_0\) is any constant, \(m\) is the module, and \(0 \leq m \leq 1; F(u_0, u_1) = (\partial/\partial p)f(x, t, u, \bar{u}, u_x, u_t)|_{p=0}\).

When \(m \to 1\) and \(m \to 0\), \(u_2^*(x, t)\) degenerates to the following approximate solutions:
\[
u_{2,1}^*(x, t) \tag{23}
\]
the approximatesolution of (1) is found. By comparing the higher power coefficients of $\rho$, more higher power approximate solutions can also be obtained, and hence the approximate solution of (1) is found.

4. Example

If $f = \varepsilon u^n$ is the disturbance term of (5), where $0 < \varepsilon \ll 1$, (5) becomes

$$u_t + c_1 u u_x + c_2 (t) u^2 u_x + c_3 u_{3x} = \varepsilon u^n.$$  \hspace{1cm} (25)

By using the above method in Section 3, one can find each order approximate solution of elliptic function form for (25) as follows:

$$u_0^* (x, t) = c_0 - \frac{6 k^2 c_1 m^2 sn (\xi, m) + 12 k^2 c_1 (m^2 - 1) cn (\xi, m)}{c_1 (sn (\xi, m) + cn (\xi, m) + dn (\xi, m))}$$

$$+ \frac{3 k^2 c_1 m^4 sn^2 (\xi, m) - 12 k^2 c_1 cn^2 (\xi, m)}{c_1 (sn (\xi, m) + cn (\xi, m) + dn (\xi, m))^2},$$

$$u_1^* (x, t)$$

$$= c_0 - \frac{6 k^2 c_1 m^2 sn (\xi, m) + 12 k^2 c_1 (m^2 - 1) cn (\xi, m)}{c_1 (sn (\xi, m) + cn (\xi, m) + dn (\xi, m))}$$

$$+ \frac{3 k^2 c_1 m^4 sn^2 (\xi, m) - 12 k^2 c_1 cn^2 (\xi, m)}{c_1 (sn (\xi, m) + cn (\xi, m) + dn (\xi, m))^2}$$

$$+ \frac{1}{2 \pi} \int_0^\infty \int_{-\infty}^{\infty} \left( -c_2 (\tau) u_0^2 u_{0\xi} + \varepsilon u_0^n \right)$$

$$\times \left[ \frac{-\lambda^3 c_3 (t - \tau) + \lambda (x - \xi)}{dx d\xi d\tau} \right].$$

5. Conclusion

This work studies the perturbed CKdV equation with variable coefficients by using the homotopic mapping method, and two degree approximate solution of the Jacobi elliptic function form are obtained, which can degenerate to solitary wave approximate solution and trigonometric function approximate solution in the limit cases. Furthermore, the approximate solution of the perturbed CKdV is also obtained. Our results show that the homotopic mapping method is applicable to the variable soliton equations. How to apply this method to high degree and high dimension system remains to be further studied.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
