Abstract

Carbon nanotubes (CTNs) show exceptional adsorption capability and high adsorption efficiency for lead removal from water. The adsorption is significantly influenced by the pH value of the solution and the nanotube surface status, which can be controlled by their treatment processing. The adsorption isotherms are well described by both Langmuir and Freundlich models. Our results suggest that CNTs can be good Pb^{2+} adsorbers and have great potential applications in environmental protection. © 2002 Elsevier Science B.V. All rights reserved.

1. Introduction

The effects of heavy metals such as lead, mercury, copper, zinc and cadmium on human health have been studied extensively. Excessive ingestion of them can cause cumulative poisoning, cancer, nervous system damage, etc [1,2]. Lead is ubiquitous in the environment and is hazardous at high levels. It is a general metabolic poison and enzyme inhibitor [3] and can accumulate in bones, brain, kidney and muscles. Long-term drinking water containing high levels of lead can cause serious disorders, such as anaemia, kidney disease and mental retardation.

Lead in wastewater comes mainly from battery manufacturing, printing, painting, dying and other industries. Unlike organic compounds, lead is non-biodegradable and, therefore, must be removed from water [4]. Various methods of lead removal from wastewater have been developed and adsorption with activated carbon is a common used method. Increasingly stringent standard on the quality of drinking water has stimulated a growing effort on the exploitation of new high efficient adsorbents.

Carbon nanotubes (CNTs), a new form of carbon, are attracting researchers’ great interest due to their exceptional mechanical properties [5] and unique electrical property [6], highly chemical...
stability and large specific surface area since their
discovery [7]. Their hollow and layered nanosized
structures make them a good candidate as adsorbers.
Long et al. [8] reported that CNTs had a
significantly higher dioxin removal efficiency than
that of activated carbon. Our previous studies
showed that CNTs are good fluoride adsorbers
and their fluoride removal capability is superior to
activated carbon [9]. In this Letter, we report that
CNTs have high lead adsorption capacity and can
be used as an adsorbent for lead removal from
water.

2. Experimental

CNTs (Fig. 1) were fabricated by catalytic
pyrolysis of the propylene–hydrogen (C3H6 : H2 =
2 : 1) mixture at 750 °C in a ceramic tube furnace
using Ni particles as catalysts. The as-grown CNTs
were dispersed in concentrated nitric acid and
refluxed at 140 °C for 1 h to remove most of the
catalyst particles. Lead stock solution (1000 mg/l)
was prepared by dissolving lead nitrate in deion-
ized water. The solution was further diluted to the
required concentrations before used.

Batch sorption isotherms were carried out in
glass tubes at room temperature. Weighed
amounts (0.05 g) of the as-grown CNTs and the
acid-refluxed CNTs were introduced into tubes,
respectively, to which 100 ml of lead solution of
increased initial concentrations (C0) from 2 to 14
mg/l with an interval of 2 mg/l were added. The pH
value of the solution at 3.0, 5.0 and 7.0 were
chosen to study the pH value effect on lead re-
moval. The glass tubes were mounted on a shaker
(HZQ-C) and shaken for 6 h at room temperature,
then the suspension was filtered through 0.45 μm
membrane filters. The filtrates were immediately
measured by an atomic adsorption spectrometer.
The amount of Pb2+ adsorbed on CNTs was
determined by the Pb2+ difference between the initial
Pb2+ concentration and the equilibrium Pb2+
concentration.

3. Results and discussion

The treatment processing has great impact on
the CNTs adsorption capability for Pb2+ removal
as demonstrated in Fig. 2. Fig. 2a shows that the
as-grown CNTs have weak adsorption capability
of Pb2+ and reach the largest adsorption capacity
of 1 mg/g as the equilibrium Pb2+ concentration
increases to 7.5 mg/l. The adsorption capacity in-
creases remarkably when the CNTs were refluxed
with concentrated nitric acid at 140 °C for 1 h. The
desorption capacity of 15.6 mg/g is obtained for
the treated CNTs at Pb2+ equilibrium concentra-
tion of 2.7 mg/l (Fig. 2b). It is already known that
the adsorption capability of activated carbon is
mainly determined by the functional groups in-
troduced by oxidation [10]. Oxidation of CNTs
with oxidized acid can also introduce many func-

![Fig. 1. TEM image of as-grown carbon nanotubes. The average diameter is about ~30 nm and the length ranges from hundreds of nanometers to micrometers.](image1)

![Fig. 2. Adsorption isotherms of Pb2+ onto CNTs. (a) the as-
grown CNTs; (b) the acid-refluxed CNTs (pH = 5.0).](image2)
tional groups, such as hydroxyl (−OH), carboxyl (−COOH) and carbonyl (>C=O), on the surface of CNTs [11]. These functional groups attached on the surfaces of the CNTs improve their adsorption capability of Pb²⁺ in solution.

The removal of Pb²⁺ from water by acid-refluxed CNTs was found to be highly dependent on the solution pH value, which affects the surface charge of the adsorbent and degree of ionization and speciation of the adsorbates. Fig. 3 shows that the Pb²⁺ adsorption capacity of the CNT increases with the pH value from 3.0 to 7.0. Precipitation will occur between Pb²⁺ and OH⁻ as the pH exceeds to 7.0, so our experiments were carried out only under acidic condition. At pH = 3.0, adsorption effect is very weak due to the competition of H⁺ with Pb²⁺ on the adsorption sites (Fig. 3a); at pH = 5.0, the adsorption capability increases due to role of functional groups on the CNTs surfaces (Fig. 3b); at pH = 7.0, the adsorption capacity increases remarkably (Fig. 3c). It has been reported that at pH between 5.5 and 11.5, the adsorption of lead by activated carbon was interfered by the precipitation of white gelatinous plumbous hydroxide [12]. The higher adsorption capacity of CNTs at pH = 7.0 may be also the cooperating role of adsorption and precipitation.

The experimental data for Pb²⁺ adsorption on acid-refluxed CNTs at different pH values could be approximated by the isotherm models of Langmuir (1) and Freundlich (2),

\[ q = \frac{q_m K_L C}{1 + K_L C}, \]  
\[ q = K_F C^{1/n}, \]

where C is the equilibrium lead concentration (mg/l), q is the amount adsorbed (mg/g) and \( q_m \) and \( K_L \) are Langmuir constants related to adsorption capacity and energy of adsorption, respectively.

It can be seen from Table 1 that both Langmuir and Freundlich models show good agreement with the experimental data, with the correlation coefficient values of 0.9945–0.9953 and 0.9877–0.9974 at different pH values. The parameters \( q_m \) and \( K_F \), which are related to the adsorption capacity, increase with pH values. This is consistent with the experimental observation.

Time course of Pb²⁺ adsorption onto the acid-refluxed CNTs was conducted using a lead solution of 10 mg/l concentration (Fig. 4). The amount of Pb²⁺ adsorbed onto the acid-refluxed CNTs increased rapidly during the beginning 8 min (16.4 mg/g adsorbent, 81.6% removal). Subsequently, the adsorption rate rises gradually and reaches equilibrium after 40 min for Pb²⁺ adsorption to reach equilibrium (17.5 mg/g, 87.8% removal). The short time needed to reach equilibrium suggests that the CNTs have very high adsorption efficiency.

![Fig. 3. Adsorption isotherms of Pb²⁺ removal by acid-refluxed CNTs at different pH values. (a) pH = 3.0; (b) pH = 5.0; (c) pH = 7.0.](image)

Table 1

| pH  | Langmuir | Freundlich |
|-----|----------|------------|
|     | \( q_m \) | \( K_L \)  | \( r^2 \)  | \( n \) | \( K_F \) | \( r^2 \)  |
| 3.0 | 1.66     | 0.1648     | 0.9953     | 1.80 | 0.3184 | 0.9945     |
| 5.0 | 17.44    | 0.5869     | 0.9953     | 1.91 | 5.9918 | 0.9877     |
| 7.0 | 49.95    | 0.1855     | 0.9945     | 1.09 | 7.7179 | 0.9974     |
and have a great potential in Pb\textsuperscript{2+} adsorbent application.

The Pb\textsuperscript{2+} adsorption on the CNTs depends on many factors such as the surface functional groups, the specific surface area and the solution components. The most important factor is the surface functional groups, which can be generated with oxidized acids. It is well known that oxidation treatment by nitric acid can cause an increase in the cation-exchange capacity and a decrease in the anion-exchange capacity of carbon\cite{10}. Different functional groups with acidic nature introduced on the CNTs surfaces can dissociate at different pH values. Conjugation of the functional groups on oxidized CNTs surfaces causes the dissociation increase of some groups to such a degree that ion exchange is also possible in a strongly acidic medium (pH = 3.0). Therefore, the CNTs could have good Pb\textsuperscript{2+} adsorption capacity at acid condition (pH = 5.0). With the increase of pH, OH\textsuperscript{-} ions in solution increase gradually and the effects of adsorption and precipitation make adsorption capacity increase significantly. In addition, the specific surface area changes from 134 to 145 m\textsuperscript{2}/g after oxidized by nitric acid. The surface area increase also benefits to the Pb\textsuperscript{2+} adsorption, but it only plays subsidiary role.

Adsorption characteristics of the heavy metals by carbon materials are much influenced by many factors, such as presence of complexing agents, pH, valency and ionic form of the metal, adsorbate concentration and adsorbent dosage\cite{12}. Here we only studied lead adsorption capability of quantitative CNTs (0.05 g) at different pH and found that at the same condition (lead: pH = 5.1; C\textsubscript{0} = 10 mg/l, adsorbent: 0.05 g) the adsorption capacity of acid-refluxed CNTs (11.2 mg/g) is higher than that of activated carbon (about 5.5 mg/g)\cite{12}. The experimental results suggest that CNTs may be an promising adsorbent for lead removal from water and detail works need to be carried out further.

4. Conclusions

In conclusion, CNTs show exceptional adsorption capability of Pb\textsuperscript{2+} from water after oxidized with nitric acid. The adsorption properties of CNTs depend significantly on the pH value of the solution. The high efficiency for Pb\textsuperscript{2+} removal by CNTs with their exceptional adsorption capability suggests that CNTs can be good Pb\textsuperscript{2+} adsorbers and have great potential applications in environmental protection.
