String junctions on backgrounds with a positively charged orientifold plane

Yosuke Imamura*

*imamura@yukawa.kyoto-u.ac.jp

Abstract

By means of the heterotic/type IIB duality, we study properties of junctions on backgrounds with a positively charged orientifold seven-plane and D-branes, which are expected to give seven dimensional $Sp(r)$ gauge theories. We give a modified BPS condition for the junctions and show that it reproduces the adjoint representation of the $Sp(r)$ group.
1 Introduction

Recent years the string theories have been bringing us a lot of information on non-perturbative properties of various gauge theories. In the context of the string theories, gauge theories are described as theories on branes. Among several ways to realize four dimensional field theories by brane configurations, in this paper, we shall focus on the construction with D3-brane probes on 7-brane backgrounds. Particles in a field theory on the D3-branes are represented by string junctions connecting some of the 7-branes and the probe D3-branes. Because the flavor symmetry of the field theory is also regarded as the gauge symmetry on the 7-branes, it is very important to study how to construct gauge theories on 7-branes with various gauge symmetries.

It is already known that we can construct theories with arbitrary simply-laced gauge groups and analyze their spectra by introducing \([p, q]\) 7-branes\[1, 2, 3, 4, 5, 6, 7, 8\]. The BPS condition for states in the field theories is represented with the self-intersection numbers of corresponding junctions. Using this condition, we can determine the spectra of field theories with ADE flavor symmetries even in the strong coupling region. However, the junction description of four dimensional field theories with non-simply-laced flavor symmetries in the strong coupling region has not been established. Especially, the BPS condition has not yet been obtained.

On the other hand, in the weak coupling limit, we can easily construct \(Sp(r)\) gauge theories as gauge theories on a stack of parallel \(r\) D-branes and an orientifold seven-plane with positive R-R charge \((O^+)\). The purpose of this paper is to study junctions on this background by means of the heterotic/type IIB duality.

One might expect that one can construct \(SO(2r+1)\) gauge theory by using an orientifold seven-plane with negative R-R charge \((O^-)\), \(r\) D7-branes and a fractional D7-brane, which is a D7-brane identified with its mirror. However, because this set of 7-branes has the non-integral monodromy

\[
M_{SO(2r+1)} = \begin{pmatrix}
-1 & 7/2 - r \\
-1 & -1
\end{pmatrix},
\]

(1)

this configuration is not allowed as a classical solution of supergravity. From the viewpoint of a field theory on \(n\) probe D3-branes, this fact implies that \(\mathcal{N} = 2\ Sp(n)\) gauge theory with \(r + 1/2\) hypermultiplets in the fundamental representation has an anomaly. (Classically, we can consider half-hypermultiplets. They are hypermultiplets whose scalars and fermions belong to \((2, 2n)\) and \((1, 2n)\) representations of \(SU(2)_R \times Sp(n)_{\text{gauge}}\) respectively.) It is nothing but the Witten’s topological anomaly\[9\]. Therefore we will not consider \(SO(2r+1)\) gauge theories on 7-branes. Furthermore, although 7-brane constructions of other non-simply-laced groups \((F_2\)
and $G_2$) are also interesting problems, we will not argue them and we will concentrate our attention to the $Sp(r)$ group.

To obtain $Sp(r)$ gauge theories on 7-branes, we should lay an $O^+$ and $r$ D7-branes in parallel. This configuration has the following monodromy.

$$M_{Sp(r)} = \begin{pmatrix} -1 & -4 - r \\ -1 & -1 \end{pmatrix}. \quad (2)$$

Because this monodromy is identical to that of a set of $8 + r$ D7-branes and an $O^-$, one might expect the BPS condition for junctions on these two backgrounds to be identical. However, in the latter, an open string going around $O^+$ with its both endpoints on one D7-brane cannot be BPS state, and it is undesirable because the string corresponds to the Cartan part of the $Sp(r)$ gauge group. This implies that we should modify the BPS condition.

In this paper, we analyze the BPS condition by means of the hetero/IIB duality. In $[10]$, the correspondence between quantum numbers of heterotic strings on $T^2$ and ones of junctions on $T^2/Z_2$ is obtained. Because all the orientifold seven planes of the $T^2/Z_2$ used in $[10]$ are $O^-$, we cannot use the result for our present purpose. In the case in of $T^2/Z_2$ containing an $O^+$, the dual is heterotic string theory compactified on $T^2$ with ‘twisted’ gauge bundle$[11]$. In Section 2, we review this duality, and we explain how the BPS condition for heterotic strings should be modified in Section 3. In Section 4, we give the one to one correspondence between quantum numbers of heterotic strings and ones of junctions and suggest the modified BPS condition for junctions. The last section is devoted to conclusions and discussions.

## 2 Heterotic/Type IIB duality

In this section we will explain the duality between $SO(32)\mathbb{Z}_2$ heterotic string theory compactified on $T^2$ with non-trivial gauge bundle structure structure and type IIB theory on $T^2/Z_2$ with three $O^-$ and one $O^+$ $[11]$. Let us start from the heterotic string theory whose $X^7$ and $X^8$ directions are compactified on $T^2$ with radii $R_7$ and $R_8$, respectively. For simplicity, we assume that the $T^2$ is rectangular and that the NS-NS 2-form field $B_{78}$ vanishes. Let us consider the maximal subgroup $O(2) \times O(16)$ of $SO(32)$. In order to realize the nontrivial structure of the gauge bundle on the torus, we should introduce Wilson lines for both the $O(2)$ and the $O(16)$ as follows:

$$X^7 \text{ direction : } \sigma_x \otimes \exp(2\pi i A^a_7 H_a), \quad X^8 \text{ direction : } \sigma_x \otimes \exp(2\pi i A^a_8 H_a). \quad (3)$$

1Precisely, the gauge group is not $SO(32)$ but $Spin(32)/\mathbb{Z}_2$. In this paper, we will not care such a point about the discrete subgroups.
The factors $\sigma_z$ and $\sigma_x$ are $O(2)$ Wilson lines, which are nothing but Pauli matrices for 2 representation. These are essential for the non-trivial structure of the gauge bundle. (In what follows, we represent this torus by $T^2_s$, while $T^2$ means a torus with trivial structure of the bundle.) Due to these Wilson lines, the gauge group $SO(32)$ is broken to $O(16)$. $H_a$ and $A^a_\mu$ ($a = 1, \ldots, 8$, $\mu = 7, 8$) are the Cartan generators and Wilson lines of this $O(16)$ respectively.

First, we should carry out the S-duality transformation to obtain type I theory on the $T^2_s$. Then, we should perform T-duality transformation along the $X^7$ direction to have type IIA theory. Because the $X^7$ direction is compactified on $S^1$ with radius $R_7$ on the type I side, the type IIA theory is compactified on $S^1/Z_2$ with length $\pi \tilde{R}_7 = \pi / R_7$. The Wilson line $\sigma_z \in O(2)$ along the $X^7$ direction breaks the gauge group $SO(32)$ to its subgroup $O(16) \times O(16)$ (Here, we assume $A^a_\mu = 0$.) and each $O(16)$ factor lives on the eight D8-branes on top of one of two orientifold eight-planes ($O8$). The $X^8$ direction is compactified on $S^1$ with radius $R_8$ as it was in the type I theory. Because of the existence of the non-trivial structure of gauge bundle on the $T^2_s$, the compactification manifold of type IIA theory is not just a direct product of the $S^1/Z_2$ and the $S^1$. Non-commutativity between the Wilson lines along the $X^7$ and the $X^8$ direction,

$$\sigma_x \sigma_z \sigma_x = -\sigma_z,$$  \hfill (4)

implies that when we go around the $S^1$ along the $X^8$ direction, we should swap the two $O8$. As a result, we have a Möbius strip as a compactification manifold of type IIA theory.

In order to perform further T-duality transformation along the $X^8$ direction to arrive at the final type IIB configuration, it is convenient to rearrange the Möbius strip to a cylinder. Namely, as is shown in Fig.1, the Möbius strip with width $\pi \tilde{R}_7$ and circumference $2\pi R_8$ (a in Fig.1) is equivalent to a cylinder with length $\pi \tilde{R}_7/2$ and circumference $4\pi R_8$ whose one boundary is $O8$ and another is capped with a cross cap (b in Fig.1). After this rearrangement, it becomes clear that the $X^8$ direction is compactified on $S^1$ with radius $2R_8$ (not $R_8$). By performing T-duality transformation along this $S^1$, we obtain $T^2/Z_2$ with radii $\tilde{R}_7/2$ and $\tilde{R}_8/2 = 1/(2R_8)$. (Radii of $T^2/Z_2$ mean radii of two cycles of the $T^2$.) By this T-duality transformation, the cross cap is transformed into an $O^-$ and an $O^+$, and the $O8$ on the boundary is transformed into two $O^-$. We will refer this compactification manifold by $T^2/Z^*_2$, while orientifold with four $O^-$ by $T^2/Z_2$.

Using this series of dualities, we can obtain some properties of $O^+$. For example, let us consider a type I D-string winding once around the $X^7$ direction, which is S-dual of a heterotic string winding around the same direction. By the first T-duality along the $X^7$ direction, this D-string is transformed into a fractional D-particle on $O8$, whose mirror image is itself, and
by the second T-duality along the $X^8$ direction it is transformed into a type IIB D-string
with winding number $1/2$. The winding number $1/2$ implies that the D-string is stretched
between two orientifold planes along the $X^8$ direction. In the cylindrical representation
of the Möbius strip ((b) in Fig1), the $O8$, on which the fractional D-particle exists, is only on
one side. Therefore, the type IIB D-string is also on the same side of the $T^2/Z^2_2$. This fact
suggests that a D-string cannot be attached to $O^+$. We can obtain the same conclusion by
starting from a type I D-string wrapped around the $X^8$ direction as follows: Because the gauge
group on the D-string is $O(1) = Z_2$, the Wilson line on it takes two values $\pm 1$. Through the
T-duality along the $X^7$ direction the D-string is transformed into a D2-brane wrapped over
the Möbius strip which inherits the Wilson line of the D-string. If we rearrange the Möbius
strip to the cylindrical representation, the length of the cycle along the $X^8$ direction become
twice. As a result, the Wilson line is squared and always becomes $+1$ regardless of the original
value. Therefore, the possible $X^8$ coordinate of the dual type IIB D-string is unique. This is
consistent with the fact that a D-string cannot be attached to $O^+$. Of course, although one
D-string cannot be attached to $O^+$, even number of D-strings can be simultaneously attached
because they can be regarded as D-strings going around $O^+$ and turning back. Furthermore,
the number of fundamental strings attached to an orientifold plane is, regardless of its charge,
always even integer. As a result, we conclude that both F-string charges and D-string charges
of strings attached to $O^+$ should always be even integers.

In the case of junctions on $T^2/Z_2$ (with four $O^-$), we can always remove strings attached to
one of four $O^-$ by adding null junctions $[\Xi]$, which can be shrinked to a point by a continuous
deformation. However, in that case, we should admit improper junctions, which contain strings with fractional charge, in order to remove a string with odd integral charge attached on the $O^-$. On the other hand, because the F-string charge and D-string charge of a string attached on $O^+$ are always even integers as we have explained, for any junction on $T^2/Z_2$, we can remove a string attached on $O^+$ without introducing such improper junctions. Therefore, we can deform any junction on $T^2/Z_2$ into ‘a standard configuration’, in which strings starting from three $O^-$ planes and eight D-branes on $O^+$ meet together at a point as is expressed in Fig.2. (If it is necessary, we should move the D7-branes.) In this configuration, arbitrary

![Figure 2: The standard configuration.](image)

junctions are specified by F-string charges $M_1$, $M_2$, $M_3$ and D-string charges $N_1$, $N_2$, $N_3$ of strings going outward from three $O^-$ and the number of strings $Q_a$ attached on $a$-th D7-brane. By means of the charge conservation, the following relations hold:

$$M_0 + M_1 + M_2 + M_3 = 0, \quad N_1 + N_2 + N_3 = 0,$$

where $M_0$ is the sum of $Q_1, \ldots, Q_8$. Therefore, we have 12 independent charges.

Due to the monodromies of 7-branes, we should introduce branch cuts and we cannot define the string charges until we fix the branch cuts. Our convention is as follows: The $T^2/Z_2$ is made of two rectangles, i.e., a rectangle on the front side and that on the back side. We assume that all the branch cuts run on the back side and that all strings run on the front side. Using this definition, we can define the string charges up to transformation $\tau \to \tau + 1$. 

5
3 The BPS condition

On the worldsheet of heterotic strings, in the light cone formalism, there are eight bosonic fields $X^i_L$ and eight fermionic fields $\psi^i$ as the left movers and 24 bosonic fields $X^i_R$ as the right movers. (We assume the left mover is supersymmetric.) Among the right movers, 16 bosonic coordinates are compactified on the self-dual even lattice and are equivalent to 32 fermionic fields through the fermionization. Let us use $\lambda^1, \ldots, \lambda^{32}$ to represent these 32 fermions. The $SO(32)$ symmetry among these real fermions gives the spacetime gauge symmetry.

At first, let us consider the heterotic string theory compactified on $T^2$ (with four $O^-$) along the $X^7$ and the $X^8$ directions. For the argument below, it is convenient to combine these real fermions into complex fermions as follows:

$$
\lambda^a_+ = \lambda^{2a-1} + i \lambda^{2a}, \quad \lambda^a_- = \lambda^{2a-1} - i \lambda^{2a}, \quad a = 1, \ldots, 16.
$$

(6)

The $\lambda^a_{\pm}$ carry a charge $\pm 1$ with respect to $a$-th $U(1)$ factor of Cartan subgroup $U(1)^{16} \subset SO(32)$. Let $A^{(16)}_{\mu} = (A^1_{\mu}, \ldots, A^{16}_{\mu}) (\mu = 7, 8)$ denote the Wilson lines for the $U(1)^{16}$. Because the fermions couple to them, the boundary condition of the fermions on a string with winding number $n_{\mu}$ depends on the Wilson line.

$$
\lambda^a_{\pm}(\sigma + 2\pi) = \exp 2\pi i (c \pm n_{\mu} A^a_{\mu}) \lambda^a_{\pm}(\sigma),
$$

(7)

where $c = 0$ for R-sector and $c = 1/2$ for NS-sector. Let $\lambda_{m}^{a\pm}$ denote the oscillators of $\lambda^a_{\pm}$ with frequency $m$, satisfying the following commutation relations:

$$
\{ \lambda_{m}^{a+}, \lambda_{n}^{b+} \} = \{ \lambda_{m}^{a-}, \lambda_{n}^{b-} \} = 0, \quad \{ \lambda_{m}^{a+}, \lambda_{n}^{b-} \} = \delta_{a,b} \delta_{m+n}.
$$

(8)

According to the boundary condition (7), the frequency $m$ of $\lambda^a_{m\pm}$ takes values in $\mathbb{Z} + c \pm n_{\mu} A^a_{\mu}$. The charges $q^a$ associated with the $a$-th $U(1)$ is given by

$$
q^a = \sum_{m \in \mathbb{Z} + c + n_{\mu} A^a_{\mu}} \lambda^a_{m+} \lambda^a_{m-}.
$$

(9)

If we use the $\zeta$ function regularization, this is rewritten as

$$
q^{(16)} = k^{(16)} - A^{(16)}_{\mu} n_{\mu},
$$

(10)

where $q^{(16)} = (q^1, \ldots, q^{16})$ and $k^{(16)}$ is a vector of normal ordered charges taking values on self-dual even lattice generated by

$$
e_1 - e_2, \quad e_2 - e_3, \quad \ldots, \quad e_{15} - e_{16}, \quad e_{15} + e_{16}, \quad \frac{1}{2} \sum_{i=1}^{16} e_i.
$$

(11)
where $\mathbf{e}_i$ are vectors such that their set $\{\mathbf{e}_1, \ldots, \mathbf{e}_{16}\}$ is the orthonormal basis. The operators $L_0$ and $\tilde{L}_0$ are given as follows:

$$L_0 = \frac{1}{4} \sum_{\mu=7,8} (p^\mu - w^\mu)^2 + N, \quad \tilde{L}_0 = \frac{1}{4} \sum_{\mu=7,8} (p^\mu + w^\mu)^2 + \tilde{N},$$

(12)

where $p^\mu$ and $w^\mu$ are Kaluza-Klein momenta and winding lengths along $X^\mu$ quantized by $w^\mu = n^\mu R_\mu$ and $p^\mu = m'_\mu / R_\mu$, respectively, where

$$m'_\mu = m_\mu + k^{(16)} \cdot A^{(16)}_\mu - \frac{1}{2} A^{(16)}_\mu \cdot A^{(16)}_\nu n^\nu, \quad m_\mu, n_\mu \in \mathbb{Z}. \quad (13)$$

The dots in (13) represent the inner products defined with metric $g_{ab} = 1_{16}$. Concerning the right movers, $\tilde{N}$ is decomposed as

$$\tilde{N} = \tilde{N}_{\text{osc}} + \frac{1}{2} q^{(16)} \cdot q^{(16)} - 1,$$

(14)

where $\tilde{N}_{\text{osc}}$ represents the contribution from excitations which do not change the fermion number $q^{(16)}$. Because $N$ should vanish for BPS states and $\tilde{N}_{\text{osc}}$ is always non-negative, we obtain the following BPS condition from the level matching condition $\tilde{L}_0 = L_0$.

$$2m'_7 n_7 + 2m'_8 n_8 + q^{(16)} \cdot q^{(16)} \leq 2.$$

(15)

Using integral indices $m_\mu, n_\mu$ and $k^{(16)}$, we have

$$2m_7 n_7 + 2m_8 n_8 + k^{(16)} \cdot k^{(16)} \leq 2.$$

(16)

This is the BPS condition for heterotic strings on $T^2$. Because these heterotic strings are related to the junctions on $T^2/\mathbb{Z}_2$, we can interpret the condition (16) as that for junctions.

When we establish the relations between quantum numbers of heterotic strings and invariant charges of the dual type IIB junctions, we should carefully take account of the dependence of the fundamental string winding numbers upon the position of D-branes as is mentioned in [12] for type I' case. If there exists a fundamental string attached on a winding D-string, the winding number of the fundamental string depends on the position of the D-string. To avoid this matter, as is done in [10], let us use the flat background on which the R-R charge is locally cancelled. On the background, the fundamental string winding numbers are independent of the positions of D-strings and the normalized Kaluza-Klein momenta $m'_\mu$ and winding numbers $n_\mu$ are identified with the F-string winding numbers $F_\mu$ and D-string winding numbers $D_\mu$ in the type IIB picture by the following simple relations:

$$F_7 = m'_7, \quad F_8 = m'_8, \quad D_7 = \frac{n_8}{2}, \quad D_8 = \frac{n_7}{2}.$$  

(17)
and each component of $q^{(16)}$ is identified with the number of strings attached to each D7-brane. After obtaining these relations one should deform the background if one want to shift to the standard configuration. Because $k^{(16)}$, $m_{\mu}$ and $n_{\mu}$ are independent of the Wilson lines $A_{\mu}^{(16)}$, once we have established the relations on the flat background, we can obtain the relations between quantum numbers in heterotic string theory with vanishing Wilson lines and invariant charges of junctions in standard configuration. The $A_{\mu}^{(16)}$ dependence of $q^{(16)}$ corresponds to the Hanany-Witten effect\cite{13, 12} and the invariant charges for D-branes $Q_a$ in the standard configuration is identified with the components of vector $k^{(16)}$. Furthermore we can represent the string charges $M_i$ and $N_i$ as follows\cite{10}.

\begin{align}
M_0 &= k^1 + \cdots + k^{16}, \\
M_1 &= -2m_8 + 2n_8 - n_9 - M_0, \quad M_2 = 2m_8 + 2m_9 - n_8 - n_9 + M_0, \quad M_3 = -2m_9 - n_8 + 2n_9 - M_0, \\
N_1 &= n_9, \quad N_2 = n_8 - n_9, \quad N_3 = -n_8.
\end{align}

By using these relations, we can show that \cite{10} is equivalent with the BPS condition for junctions given in \cite{7, 8}.

Next, let us discuss the compactification of heterotic string theory on $T^2$ and observe how the condition \cite{10} is modified. As we have explained in Section 3, the nontrivial structure of the gauge bundle is realized by the Wilson line (3). However, for our purpose, it is convenient to use another subgroup $Sp(1) \times Sp(8)$ and the following Wilson lines:

\begin{align}
X^7 \text{ direction} : i\sigma_z \otimes \exp(2\pi i A_7^a H_a), \quad X^8 \text{ direction} : i\sigma_x \otimes \exp(2\pi i A_8^a H_a),
\end{align}

where $i\sigma_z$ and $i\sigma_x$ are elements of the $Sp(1)$ and $H_a$ ($a = 1, \ldots, 8$) are the Cartan generators of the $Sp(8)$. In this formulation, the gauge symmetry $Sp(8)$ appears when $A_\mu^{(8)} = 0$. In order to obtain the modified BPS condition, we have to quantize the worldsheet fermions taking account of the Wilson lines (21). When both the winding numbers $n_8$ and $n_9$ are even, the boundary condition of fermions is same as that of strings on $T^2$ with Wilson line $A_\mu^{(16)} = (A_\mu^{(8)}, A_\mu^{(8)})$ where $A_\mu^{(8)}$ are Wilson lines of the $Sp(8)$ subgroup appearing in (21) and we can use the result for strings on $T^2$. The eight components of $A_\mu^{(8)}$ represent the positions of eight D7-branes on $T^2/Z_2$, and the invariant charges representing the numbers of strings attached to these D7-branes are charges coupling to the $A_\mu^{(8)}$. The charge vector and normal ordered one are given by

\begin{align}
q^{(8)} &= q^{(1)} + q^{(2)}, \quad k^{(8)} = k^{(1)} + k^{(2)},
\end{align}
where \( q^{(i)} \) and \( k^{(i)} \) are former and latter half of the charge vectors defined by (9).

\[
q^{(16)} = (q^{(1)}, q^{(2)}), \quad k^{(16)} = (k^{(1)}, k^{(2)}).
\]

(23)

Because \( k^{(16)} \) is on the self-dual even lattice, \( k^{(8)} \) takes values on the \( Sp(8) \) root lattice generated by

\[
-2e_1, \quad e_1 - e_2, \quad e_2 - e_3, \quad \ldots, \quad e_7 - e_8.
\]

(24)

A state of a string on the torus \( T^2_* \) is specified by giving winding numbers \( n_\mu \), Kaluza-Klein indices \( m_\mu \) and \( U(1) \) charges \( q^{(8)} \). In the case of \( T^2 \) compactification, Kaluza-Klein indices \( m_\mu \) are integral numbers. However, now, we should take account of the effect of \( Sp(1) \) Wilson lines \( i\sigma_z \) and \( i\sigma_x \). Because the eigen values for these operators on GSO even states are \( \pm 1 \), their effect is expressed by allowing \( m_\mu \) to be half integers. Let us define integral labels

\[
m_\mu = 2 m_\mu.
\]

Using these variables, the quantization of Kaluza-Klein momenta (13) is rewritten as

\[
m'_\mu = \frac{1}{2} \left( m_\mu + k^{(8)} \cdot \overline{A}_\mu^{(8)} - \frac{1}{2} \overline{A}_\mu^{(8)} \cdot \overline{A}_\nu^{(8)} n_\nu \right),
\]

(26)

where the inner products are defined with the metric \( 1_8 \). By substituting these equation into (13), we obtain the BPS condition for heterotic strings on the \( T^2_* \) as

\[
2m_7 n_7 + 2m_8 n_8 + k^{(8)} \cdot k^{(8)} + (k^{(1)} - k^{(2)})^2 \leq 4.
\]

(27)

Let us define a function \( f(k^{(8)}) \) as follows.

\[
f(k^{(8)}) = \min_{k^{(8)} \text{fixed}} (4 - (k^{(1)} - k^{(2)})^2).
\]

(28)

Because the vector \( k^{(16)} = (k^{(1)}, k^{(2)}) \) is on the self-dual even lattice, we can represent \( f(k^{(8)}) \) in the following way.

\[
f(k^{(8)}) = |4 - \#(\text{odd components of } k^{(8)})|.
\]

(29)

Because the sum of all the components of \( k^{(8)} \) is even, \( f(k^{(8)}) \) is always 0, 2 or 4. Using this function, (27) is rewritten as

\[
2m_7 n_7 + 2m_8 n_8 + k^{(8)} \cdot k^{(8)} \leq f(k^{(8)}).
\]

(30)
This is the modified BPS condition for heterotic strings on $T^2_{\ast}$. Until now, in the deduction of (30), we have supposed $n_{\mu} \in 2\mathbb{Z}$. However, we can show that the same inequality is obtained for any winding number as follows: In the sector with $(n_7, n_8) = (1, 0) \mod 2$, the boundary condition of worldsheet fermions is identical to that for heterotic strings on $T^2$ with Wilson lines $A_8^{(16)} = (A_8^{(8)} + s^{(8)}/2, A_8^{(8)} - s^{(8)}/2)$ with $s^{(8)}$ an eight-dimensional vector with all the components $1/2$. Because the BPS condition is independent of the Wilson lines, we have the same result for this sector. Furthermore, because other two sectors $(n_8, n_9) = (0, 1)$ and $(1, 1) \mod 2$ can be obtained from the $(1, 0)$ sector by the modular transformation of the torus, the condition for these sectors should also be the same.

For heterotic strings on $T^2$, if a set of the quantum numbers $\{m_{\mu}, n_{\mu}, k^{(16)}\}$ is specified, there exists at least one state having the given quantum numbers, and if the set of quantum numbers satisfies the BPS condition, at least one BPS state exists. However, for heterotic strings on $T^2_{\ast}$, it is not the case. For example, let us consider states with $n_7 = n_8 = 0$ and $k^{(8)} \cdot k^{(8)} = 4$. For these states to be BPS states, all the components of $k^{(8)}$ should be even or odd, and $k^{(8)}$ should have one nonzero component $\pm 2$. There are 16 such states $\lambda_{-1/2}^{a \pm 2} \lambda_{-1/2}^{a + 8 \pm 0}$. These are what become massless when $Sp(8)$ gauge group is enhanced on the $O^+$ and correspond to the long roots of $Sp(8)$ Lie algebra. (Generally, $Sp(k)$ has $2k$ long roots with norm 4.) Because the eigenvalues of $i\sigma_x, i\sigma_z \in Sp(1)$ for these states are $+1$, the quantum numbers $m_{\mu}$ should be even integers. In other words, although the set of quantum numbers $\{m_{\mu}, n_{\mu}, k^{(8)}\}$ with $n_{\mu} = 0$, $k^{(8)} \cdot k^{(8)} = 4$ and $m_8 m_9 \notin 4\mathbb{Z}$ satisfies the BPS condition (30), there are no BPS states with the quantum numbers. (As a result, we have $Sp(8)$ gauge group only on one orientifold plane.)

4 Relation between quantum numbers

In this section, we will explain how we can obtain the one to one correspondence between quantum numbers of heterotic strings on $T^2_{\ast}$ and invariant charges of junctions on $T^2/\mathbb{Z}_2^\ast$. It is an variation of the relation between Het/$T^2$ and IIB/($T^2/\mathbb{Z}_2$) given in [10].

Via the duality explained in Section 2, the D-string winding numbers $D_{\mu}$ and the F-string winding numbers $F_{\mu}$ on the flat $T^2/\mathbb{Z}_2^\ast$ is related to the quantum numbers of heterotic strings on $T^2_{\ast}$ as follows:

$$ F_7 = 2m_7', \quad F_8 = 2m_8', \quad D_7 = -\frac{1}{2}n_8, \quad D_8 = \frac{1}{2}n_7. $$

Comparing to (17), the reason for the existence of extra 2 factors for $F_{\mu}$ is that, because the size of the $T^2/\mathbb{Z}_2^\ast$ is half of that of $T^2/\mathbb{Z}_2$, in order to give the same energy the winding numbers
should be twice as \[^{17}\]. These extra 2 factors are compensated by the extra \(1/2\) factor in \[^{26}\]. Therefore, it is expected that we obtain the exactly same relations between \(\{\overline{m}_\mu, n_\mu, k^{(8)}\}\) and \(\{D_\mu, F_\mu\}\) as that for the Het/T\(^2\) - IIB/(T\(^2\)/Z\(^2\)) duality given in \[^{10}\]. However, there is one problem. To use the relation \[^{31}\], we should use the flat background. Because, unlike the orientifold with four \(O^-\), the positive R-R charge of the \(O^+\) cannot be canceled by the D7-brane charge, there is no BPS flat background.

This obstruction can be overcome by using a non-BPS flat background as follows: If we allow non-BPS configurations, we can make a flat background by setting four anti-D7-branes on top of the \(O^+\). This brane configuration gives the gauge group \(SO(8)^4\) with rank 16. This

![Figure 3: The flat background with three \(O^-\) and one \(O^+\). Each bullet represent a stack of four D7-branes and a circle is a set of four anti-D7-branes.](image)

implies that vectors \(k^{(8)}\), \(q^{(8)}\) and \(\overline{A}_\mu^{(8)}\) should be extended to 16-dimensional vectors. This can be done in the following way. Let us consider the situation in which \(d\) D7-branes and \(d\) anti-D7-branes are created at a certain point on the \(T^2/Z_2^*\). Then 8 dimensional vectors should be extended to \(8+2d\) dimensional vectors. Let us define \(A^{(8+d,d)}_\mu\) as vectors representing the positions of branes and anti-branes. We assume the former \(8+d\) components of \(A^{(8+d,d)}_\mu\) represent the positions of \(8+d\) D-branes and latter \(d\) components represent the positions of the \(d\) anti-D-branes. If the \(d\) D-branes and the \(d\) anti-D-branes are stacked at a point, and junction does not attached on them, the quantization \[^{28}\] should not change. This is achieved by introducing the metric \(g_{\mu\nu} = \text{diag}(1_{8+d}, -1_d)\). Furthermore, if we demand that when a D-brane and an anti-D-brane are on top of each other, an open string connecting them should not contribute to the string winding number obtained by \[^{26}\], we should define \(q^{(8+d,d)}\) as a
vector whose former $8 + d$ components represent the number of strings going out from each D-brane while latter $d$ components represents the number of strings going into each anti-D7-brane. Under this definition, $\mathbf{A}_\mu^{(8+d,d)}$ dependence of $q^{(8+d,d)}$ representing the Hanany-Witten effect can be given in the same equation as (23):

$$q^{(8+d,d)} = k^{(8+d,d)} - \mathbf{A}_\mu^{(8+d,d)} n_\mu.$$  \hspace{1cm} (32)

In this way, we can extend the vectors to 16-dimensional vectors ($d = 4$) and we can realize the flat background, on which the relations (31) are available. Once we have obtained the relations (31), in the same way as we explained in Section 3 in the case of Het/$T^2$ and IIB/($T^2/Z_2$), we can obtain the following relation for the string charges of junctions on the background with 12 D7-branes and 4 anti-D7-branes near the $O^+$.

$$M_0 = \sum_{a=1}^{12} k'^a - \sum_{a=13}^{16} k'^a.$$ \hspace{1cm} (33)

$$M_1 = -2m_8 + 2n_8 - n_9 - M_0, \quad M_2 = 2m_8 + 2m_9 - n_8 - n_9 + M_0, \quad M_3 = -2m_9 - n_8 + 2n_9 - M_0,$$

$$N_1 = n_9, \quad N_2 = n_8 - n_9, \quad N_3 = -n_8.$$ \hspace{1cm} (34, 35)

(We use $k'^a$ to represent the components of the $k^{(8+d,d)}$, while the components of $k^{(8)}$ are $k^a$.)

To obtain the standard configuration with eight D7-branes, four pairs of D7-branes and anti-D7-branes should be annihilated. In this process, the gauge group $U(12) \times U(4)$ is broken to $U(8)$ by means of the tachyon condensation[14]. After the condensation, we have eight charges $k^a$ instead of $k'^a$. Unless we specify the pattern of the tachyon condensation, we cannot represent $k^a$ by $k'^a$. However, because the $U(1)$ is not broken by the tachyon condensation, the total charge coupled with the diagonal $U(1)$ is unchanged and the equation (33) is replaced by

$$M_0 = \sum_{a=1}^{8} k^a.$$ \hspace{1cm} (36)

Because the relations (33), (34) and (35) are identical to the relation appearing in Het/$T^2$-IIB/($T^2/Z_2$) duality, the left hand side of (30) must be rewritten to the identical expression to what is given in [10]. As a result, we obtain the following BPS condition for junctions:

$$(J, J) \leq f(k^{(8)}),$$ \hspace{1cm} (37)

where the left hand side is the self intersection number of junction $J$ obtained by means of the formula given in [2] and $f(k^{(8)})$ is the function defined by (28). However, as we mentioned
above, we should note that even this equation hold, the existence of the corresponding BPS junction is not guaranteed.

Let us consider the decompactification limit in the type IIB theory and look at the vicinity of \( O^+ \). We suppose \( r \) of eight D7-branes are left near the \( O^+ \) and other \( 8-r \) D7-branes are decoupled. In this limit, only the states with \( \mathbf{m}_\mu = n_\mu = k^{r+1} = k^{r+2} = \cdots = k^8 = 0 \) are left. The BPS condition is given by

\[
(J, J) = k \cdot k \leq f(k),
\]

where \( k \) is \( r \)-dimensional charge vector on the \( Sp(r) \) root lattice representing the numbers of the strings attached to the \( r \) D7-branes. Although the function \( f(k) \) was originally defined for the eight dimensional vector, we can use the same definition for the vector of dimension \( r < 8 \) because the definition \((29)\) is unaffected by extra zero components. Although we cannot use the heterotic / type IIB duality for \( r > 8 \), let us assume the same BPS condition holds. Then we find that the adjoint representation of \( Sp(r) \) gauge group are reproduced as follows: Let \( n_{\text{odd}} \) denote the number of odd components of a vector \( k \). The norm \( k \cdot k \) is always equal with or larger than \( n_{\text{odd}} \) and the following inequality should hold for BPS states.

\[
n_{\text{odd}} \leq k \cdot k \leq |4 - n_{\text{odd}}|.
\]

Due to this equation, only two values 0 and 2 is allowed for \( n_{\text{odd}} \). When \( n_{\text{odd}} = 0 \), the vector \( k \) should satisfy \( k \cdot k \leq 4 \). Therefore, all the components are zero or only one component is \( \pm 2 \) and others are zero. They give the Cartan generators and the long roots of \( Sp(r) \) gauge group. When \( n_{\text{odd}} = 2 \), two components of \( k \) are \( \pm 1 \) and they correspond to the short roots of \( Sp(r) \). Collecting these states altogether, we obtain the adjoint representation of the \( Sp(r) \).

## 5 Conclusions and discussions

We investigated the duality between heterotic strings on torus with nontrivial gauge bundle structure \( T^2 \) and junctions on background containing an \( O^+ \). First, we gave the BPS condition for heterotic strings on \( T^2 \), Using the correspondence between quantum numbers of heterotic strings and junctions established on a non-BPS flat background, we obtained the modified BPS conditions for junctions on \( T^2 / \mathbb{Z}_2 \). By means of this condition, we could reproduce the adjoint representation of \( Sp(r) \) gauge group on the \( O^+ \).

As we mentioned in Introduction, string junctions are very useful tools for analyzing non-perturbative spectra of supersymmetric Yang-Mills theories on the probe D3-branes. The
gauge theory on \( n \) D3-branes on a background with an \( O^+ \) and \( k \) D7-branes is \( \mathcal{N} = 2 \) supersymmetric \( \text{SO}(2n) \) gauge theory with \( k \) hypermultiplets. For complete analysis of this theory, we need the BPS conditions for junctions attached on the probe D3-branes on a background with an \( O^+ \). If we had obtained it, we would be able to know the complete spectrum of BPS particles of the theory. However, unfortunately, our argument with the perturbative heterotic strings is not sufficient for the purpose because dual of D3-branes are solitonic five-branes and our argument here did not contain them.
