Abstract
The electroseismic model describes the coupling phenomenon of the electromagnetic waves and seismic waves in fluid immersed porous rock. Electric parameters have better contrast than elastic parameters while seismic waves provide better resolution because of the short wavelength. The combination of these two different waves is prominent in oil exploration. Under some assumptions on the physical parameters, we derived a Hölder stability estimate to the inverse problem of recovery of the electric parameters and the coupling coefficient from the knowledge of the fields in a small open domain near the boundary. The proof is based on a Carleman estimate of the electroseismic model.

Keywords: electro-seismic model, Biot’s system, Hölder stability, Carleman estimate

1. Introduction
The traveling of seismic waves underground generates electromagnetic (EM) waves and vice versa. This phenomena, electro-kinetic coupling, is explained by the electro-kinetic theory, which considers that the sediment layers of the earth are porous media saturated with fluid electrolyte. The solid grains of porous media carry extra electric charges (usually negative) on their surfaces as a result of the chemical reactions between the ions in the fluid and the crystals that compose the solid. These charges are balanced by ions of opposite sign in the
fluid, forming thus an electrical double layer. When seismic waves propagate through porous media, the relative solid-fluid motion induces an electrical current which is a source of EM waves. Conversely, when EM waves pass through such porous media, ions in the fluid are set in motion and drag the fluid as well, because of viscous traction.

Electro-kinetic coupling has been observed by geophysicist, see e.g. [10, 12, 24]. This effect rose interest in the physics community, as the coupling of EM and seismic waves may provide an efficient tool for imaging the subsoil in view of oil prospection. Such an imaging technique, and the associated inverse problem of reconstructing the constitutive parameters of the subsoil, fall into the category of multi-physics inverse problems, where a medium is probed using two types of waves (see for example [1, 17] and references therein for medical imaging). One type of waves is very sensitive to the contrast in the parameters that describe the properties of the medium (electric permittivity, magnetic permeability and conductivity in our case) however, these waves are usually very diffusive and only scattered information arrives to the medium boundary, where the data are collected. The other type, on the contrary, is not very sensitive to changes in the medium properties, but is able to carry information through the medium with little distortion (seismic waves in our case).

In 1994, Pride [18] derived a macroscopic model in the frequency domain that models the coupling of EM and seismic waves in fluid-saturated porous media by averaging microscopic properties, see also [19, 20]. The associated system of equations is composed of the Maxwell equations, which govern the propagation of EM waves, and of the Biot equations [5], which govern the propagation of seismic waves in porous media.

Because the electro-kinetic coupling is very weak in practice, one usually neglects multi-conversion, i.e. one neglects the coupling terms in either the Maxwell or the Biot equations, and thus only considers transformations from either EM to seismic waves (electroseismic) or from seismic to EM waves (seismoelectric). At low frequency, one can expand all the parameters of the model with respect to frequency, and neglecting high order terms results in a time domain model. This is done for example in [11] for the seismoelectric model. In our paper, we are interested in the electroseismic model, which takes the form

\[
\partial_t \mathbf{D} - \text{curl} (\alpha \mathbf{B}) + \gamma \mathbf{D} = 0, \tag{1.1}
\]

\[
\partial_t \mathbf{B} + \text{curl} (\beta \mathbf{D}) = 0, \tag{1.2}
\]

\[
\rho \partial_t^2 \mathbf{u} + \rho_f \partial_t^2 \mathbf{w} - \text{div} \mathbf{\tau} = 0, \tag{1.3}
\]

\[
\rho_f \partial_t^2 \mathbf{u} + \rho_e \partial_t^2 \mathbf{w} + \nabla p + \eta \partial_t \mathbf{w} - \xi \mathbf{D} = 0, \tag{1.4}
\]

\[
(\lambda \text{div} \mathbf{u} + C \text{div} \mathbf{w}) \mathbf{I} + G(\nabla \mathbf{u} + \nabla \mathbf{u}^T) = \mathbf{\tau}, \tag{1.5}
\]

\[
C \text{div} \mathbf{u} + M \text{div} \mathbf{w} = -p, \tag{1.6}
\]

where

\[
\alpha = \frac{1}{\mu}, \quad \beta = \frac{1}{\varepsilon}, \quad \gamma = \frac{\sigma}{\varepsilon}, \quad \xi = \frac{L_\eta}{\kappa \varepsilon}.
\]

The physical meaning of all the variables and parameters is given in table 1. All the parameters are real and positive. Throughout the text, we denote by \( \partial_t \) and \( \partial_j \) the partial derivatives of a function with respect to \( t \) and \( x_j \), respectively, and by \( \nabla \) (resp. \( \nabla_{x_j} \)) the gradients with respect to the variables \( \mathbf{x} \) (resp. \( x_j \) and \( t \)). By gradient of a vector-valued function, we mean the transpose of the Jacobian matrix.
To close the Maxwell system (1.1) and (1.2), we assume that the media do not contain any free charge, i.e.

$$\text{div} \mathbf{D} = \text{div} \mathbf{B} = 0.$$  \hspace{1cm} (1.7)

We consider the system of equations (1.1)-(1.7) in $Q = \Omega \times (-T,T)$ where $\Omega \in \mathbb{R}^3$ is a bounded domain with $C^\infty$ boundary $\partial \Omega$. The boundary conditions are

$$\mathbf{n} \times \mathbf{D} = 0, \quad \mathbf{n} \cdot \mathbf{B} = 0, \quad \mathbf{n} \cdot \boldsymbol{\tau} = 0, \quad p = 0, \quad \text{on} \quad \partial \Omega,$$  \hspace{1cm} (1.8)

where $\mathbf{n}$ is the outer normal vector on $\partial \Omega$. As we are interested in the electroseismic model, we consider $0$ initial values for the solid displacement $\mathbf{u}$ and for the relative fluid displacement $\mathbf{w}$ associated to the Biot equations

$$\mathbf{u}(\mathbf{x},0) = 0, \quad \mathbf{w}(\mathbf{x},0) = 0, \quad \partial_t \mathbf{u}(\mathbf{x},0) = 0, \quad \partial_t \mathbf{w}(\mathbf{x},0) = 0,$$  \hspace{1cm} (1.9)

while we impose electric and magnetic fluxes in $\Omega$

$$\mathbf{D}(\mathbf{x},0) = \mathbf{D}_0(\mathbf{x}), \quad \mathbf{B}(\mathbf{x},0) = \mathbf{B}_0(\mathbf{x}).$$  \hspace{1cm} (1.10)

In accordance with the accepted physical properties of underground media, we assume that the matrices

$$
\begin{pmatrix}
\rho & \rho_f \\
\rho_f & \rho_e
\end{pmatrix}
$$

and

$$
\begin{pmatrix}
\lambda & C \\
C & M
\end{pmatrix}
$$

are symmetric positive definite and that $\rho_e > \rho_f, \rho > \rho_f$. We also assume that all the parameters of the Biot equations (1.3)-(1.6) are known, except the coupling coefficient $\xi$. The main object of this paper is to analyse the well-posedness of the inverse problem of determining the parameters $(\alpha, \beta, \gamma, \xi)$ from measurements of $(\mathbf{D}, \mathbf{B}, \mathbf{u}, \mathbf{w})$ in $Q_\omega$, where $Q_\omega = \omega \times (-T,T)$ and $\omega \subset \Omega$ is a fixed neighborhood of the boundary. To the best of our knowledge, [7] and its following work [6] are the only papers considering the inverse electroseismic problem. In those papers, the authors considered the second inversion step in frequency domain, assuming that $\mathbf{L}$ is known everywhere in $\Omega$, they focus on the identification of $(L, \sigma)$. Their method is based on the CGO solutions of frequency domain Maxwell equations [8, 22]. Different

| **Table 1.** Physical meanings of variables and parameters. |
|------------------|--------------|
| **D**            | Electric flux |
| **u**            | Solid displacement |

| **\sigma**       | Electric conductivity |
| **\mu**          | Magnetic permeability |
| **\kappa**       | Fluid flow permeability |
| **\lambda, G**   | Lamé elastic parameters |
| **\rho**         | Bulk density |
| **\rho_e**       | Equivalent density |
| **B**            | Magnetic flux |
| **w**            | Relative fluid displacement |
| **p**            | Pore pressure |
| **\varepsilon**  | Electric permittivity |
| **L**            | Electro-kinetic parameter |
| **\eta**         | Fluid viscosity |
| **C, M**         | Biot moduli parameters |
| **\rho_f**       | Fluid density |
from their work, our method treats the global inversion and is based on a Carleman estimate to the electroseismic model [3, 15, 16]. Under some assumptions on the physical parameters we derive a Hölder stability estimate to the inverse problem of identification of the electric parameters and the coupling coefficient with only measurements near the boundary. The main stability result is provided in theorem 4.1.

The paper is organized as follows: section 2 is devoted to the existence and uniqueness of solutions to the forward problem. In section 3, we derive a Carleman estimate for the whole electroseismic system, from which we infer, in section 4, the Hölder stability of the inverse problem with measurements of \((D, B, u, w)\) near the boundary.

2. Existence and uniqueness for Biot’s system

As stated before, in the electroseismic system the Maxwell equations are totally independent of the Biot equations. Therefore, the question of existence and uniqueness of solutions to the electroseismic system reduces to showing existence and uniqueness of solutions to the Biot equations. To the author’s best knowledge, existence and uniqueness for the Biot equations in two dimension was first proved in [21]. In [3], the 3D case is studied, but with different boundary conditions than those considered here. Although the general arguments are similar, we prove the existence and uniqueness of solutions to our version of the Biot equations for the sake of completeness.

We first introduce some notations. For two matrices \(E = (E_{ij}), F = (F_{ij})\) of the same size, we define

\[
E : F = \sum_{ij} E_{ij} F_{ij}.
\]

For a given Hilbert space \(H\), \((u, v)_H\) denotes the inner product of \(u, v \in H\) and \(\|u\|_H\) the corresponding norm. The dual space of \(H\) is denoted by \(H’\) and \((u, f)\) represents the duality pairing of \(u \in H, f \in H’\). We use \(H^m\) to denote the space of vector-valued functions \(u = (u_1, \ldots, u_m)\) such that \(u_j \in H, 1 \leq j \leq m\). The inner product on this space is defined by \((u, v)_H = \sum_j (u_j, v_j)_H\). We use similar definitions for spaces of matrix-valued functions. When we consider the space \(L^2(\Omega)\) or \([L^2(\Omega)]^m\), we usually omit all subscripts. The Sobolev space \(H(\text{div}, \Omega)\) is defined by

\[
\{ u \in [L^2(\Omega)]^3 : \text{div} u \in L^2(\Omega) \}
\]

and is equipped with the inner product

\[
(u, v)_{H(\text{div})} = (u, v) + (\text{div} u, \text{div} v).
\]

We use \(L^p(-T, T; H)\) to denote the space of functions \(f : (-T, T) \to H\) satisfying

\[
\|f\|_{L^p(-T, T; H)} := \left( \int_{-T}^T \|f(t)\|^p_H dt \right)^{1/p} < \infty
\]

for \(1 \leq p < \infty\), and define

\[
\|f\|_{L^\infty(-T, T; H)} := \text{ess sup}_{t \in (-T, T)} \|f\|_H < \infty.
\]

Denoting \(V = [H^1(\Omega)]^3 \times H(\text{div}, \Omega), v_1 = u, v_2 = w,\)

\[
v = \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \quad F = \begin{pmatrix} 0 \\ \alpha D \end{pmatrix},
\]
\[ A = \begin{pmatrix} \rho I_3 & \rho I_3 \\ \rho I_3 & \rho I_3 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 \\ 0 & \frac{1}{2}I_3 \end{pmatrix}, \quad \mathcal{L}v = \begin{pmatrix} -\nabla \tau \\ \nabla p \end{pmatrix}, \]

the Biot equations can be compactly written in the form
\[
\begin{cases}
A \partial_t^2 v + B \partial_t v + \mathcal{L}v = F, & \text{in } \Omega \times (-T, T), \\
v(x, 0) = 0, & \text{in } \Omega, \\
\partial_t v(x, 0) = 0, & \text{in } \Omega, \\
\mathbf{n} \cdot \tau = 0, \quad p = 0, & \text{on } \partial \Omega \times (-T, T). 
\end{cases} \tag{2.1}
\]

Integration by parts and using the boundary conditions, we have
\[
\langle \mathcal{L}v, v' \rangle = \int_{\Omega} (-\nabla \tau \cdot v'_1 + \nabla p \cdot v'_2)
= \int_{\Omega} (\nabla v'_1 - p \nabla v'_2)
= (\text{div } v_1, \lambda \text{div } v'_1 + C \text{div } v'_2) + (\text{div } v_2, \text{Cdiv } v'_1 + M \text{div } v'_2) + (2Ge(v_1), e(v'_1)),
\]
where \(e(v_1) = \frac{1}{2} \langle \nabla v_1 + \nabla v_1' \rangle\).

Define
\[
\mathcal{B}(v, v') = (\text{div } v_1, \lambda \text{div } v'_1 + C \text{div } v'_2) + (\text{div } v_2, \text{Cdiv } v'_1 + M \text{div } v'_2) + (2Ge(v_1), e(v'_1)).
\]

It’s obvious that \(\mathcal{B}\) is a symmetric bounded bilinear form. We recall the Korn inequality
\[
(e(v_1), e(v'_1)) \geq C_0 ||v_1||^2_{H^1} - ||v_1||^2,
\]
where \(C_0\) is a strictly positive constant. From now on, we use \(C_0\) to denote a general positive constant which may take different values at different places. From the Korn inequality, we obtain
\[
\mathcal{B}(v, v) \geq \int_{\Omega} (\text{div } v_1, \text{div } v_2) \left( \begin{array}{cc} \lambda & C \\ C & M \end{array} \right) \left( \begin{array}{c} \text{div } v_1 \\ \text{div } v_2 \end{array} \right) \, dx + 2 \min \{G\} \langle e(v_1), e(v_1) \rangle
\geq \lambda_\ast ||v_1||^2 + \lambda_\ast ||v_2||^2 + 2C_0 \min \{G\} ||v_1||^2_{H^1} - 2 \min \{G\} ||v_1||^2
\geq C_0 ||v||^2 - \theta ||v||^2,
\]
where \(\theta\) is a positive constant independent of \(v\) and \(\lambda_\ast\) is the smallest eigenvalue of the matrix
\[
\left( \begin{array}{cc} \lambda & C \\ C & M \end{array} \right).
\]

We define \(\mathcal{B}_\theta(v, v') = \mathcal{B}(v, v') + \theta(v, v').\) The bilinear form \(\mathcal{B}_\theta\) is symmetric, bounded, and it satisfies the following ellipticity condition \(\mathcal{B}_\theta(v, v) \geq C_0 ||v||^2_{H^1}\).

**Definition 2.1.** Let \(\mathbf{F} \in H^1(-T, T; [L^2(\Omega)]^6)\). We call \(\mathbf{r} \in L^\infty(-T, T; V)\) a generalized solution to (2.1) if it satisfies
\[
(A \partial_t^2 \mathbf{r}(t), v) + (B \partial_t \mathbf{r}(t), v) + \mathcal{B}(\mathbf{r}(t), v) = \langle \mathbf{F}(t), v \rangle \quad \text{a.e. } t \in (-T, T) \tag{2.2}
\]
for any \(v \in V\).

Note that the scalar products in this definition only involve the \(x\) variable. We can now state the existence and uniqueness theorem for the Biot equations.
Theorem 2.1. Let \( F \in H^1(-T, T; [L^2(\Omega)]^6) \). Then the system (2.1) has a unique weak solution \( r(x, t) \) such that 
\[
\mathbf{r}, \partial_t \mathbf{r} \in L^\infty(-T, T; V(\Omega)), \quad \text{and} \quad \partial_t^2 \mathbf{r} \in L^\infty(-T, T; [L^2(\Omega)]^6).
\]

Proof. Since \( V \) is separable, there exists a sequence of linearly independent functions \( \{\psi^{(n)}\}_{n \geq 1} \) which form a basis of \( V \). Let us define 
\[
S_m = \text{span} \left\{ \psi^{(1)}, \psi^{(2)}, \ldots, \psi^{(m)} \right\},
\]
and choose 
\[
r^{(m)}(t) = \sum_{j=1}^{m} g_{jm}(t) \psi^{(j)}
\]
such that \( r^{(m)}(0) \to 0, \partial_t r^{(m)}(0) \to 0 \). The functions \( g_{jm}(t) \) are determined by the system of ordinary differential equations 
\[
(A\partial_t^2 r^{(m)}, \psi) + (B\partial_t r^{(m)}, \psi) + \mathcal{B}(r^{(m)}, \psi) = (F, \psi), \quad \psi \in S_m. \tag{2.3}
\]
Next we prove two a priori estimates of \( r^{(m)}(t) \). By choosing \( \psi = \partial_t r^{(m)} \), we obtain 
\[
(A\partial_t^2 r^{(m)}, \partial_t r^{(m)}) + (B\partial_t r^{(m)}, \partial_t r^{(m)}) + \mathcal{B}(r^{(m)}, \partial_t r^{(m)}) = (F, \partial_t r^{(m)}). \tag{2.4}
\]
Let \( \Lambda(t) = \|A^{1/2} \partial_t r^{(m)}(t)\|^2 + \mathcal{B}_g(r^{(m)}(t), r^{(m)}(t)) \). Since \( \mathcal{B}_g \) is elliptic, \( \Lambda(t) \) can be lower bounded by 
\[
\Lambda(t) \geq C_0 (\|r^{(m)}(t)\|^2 + \|\partial_t r^{(m)}(t)\|^2)
\]
and from (2.4)
\[
\frac{d}{dt} \Lambda(t) \leq C_0 (\|F(t)\|^2 + \|r^{(m)}(t)\|^2 + \|\partial_t r^{(m)}(t)\|^2).
\]
Integrating from 0 to \( t \) yields 
\[
\Lambda(t) \leq C_0 \int_0^t \|F(\tau)\|^2 d\tau + \Lambda(0) + C_0 \int_0^t \left( \|r^{(m)}(\tau)\|^2 + \|\partial_t r^{(m)}(\tau)\|^2 \right) d\tau.
\]
Since \( \Lambda(0) = \|A^{1/2} \partial_t r^{(m)}(0)\|^2 + \mathcal{B}_g(r^{(m)}(0), r^{(m)}(0)) \) and \( r^{(m)}(0), \partial_t r^{(m)}(0) \to 0 \), \( \Lambda(0) \) is bounded by a constant \( C_0 \) independent of \( m \). We conclude that 
\[
\|r^{(m)}(t)\|^2 + \|\partial_t r^{(m)}(t)\|^2 \leq C_0 + C_0 \int_0^t \left( \|r^{(m)}(\tau)\|^2 + \|\partial_t r^{(m)}(\tau)\|^2 \right) d\tau \tag{2.5}
\]
and by the Gronwall inequality 
\[
\|r^{(m)}(t)\|^2 + \|\partial_t r^{(m)}(t)\|^2 \leq C_0 \tag{2.6}
\]
where \( C_0 \) is independent of \( t \) and \( m \). Taking the time derivative of (2.3) and choosing \( \psi = \partial_t^2 r^{(m)} \), we have
(A\partial_t^3 r^{(m)}, \partial_t^2 r^{(m)}) + (B\partial_t^2 r^{(m)}, \partial_t^2 r^{(m)}) + \mathcal{B}(\partial_t r^{(m)}, \partial_t^2 r^{(m)}) = (\partial_t F, \partial_t^2 r^{(m)}).
\]

(2.7)

Following the same process that leads to (2.6), we obtain
\[\|\partial_t r^{(m)}(t)\|_V^2 + \|\partial_t^2 r^{(m)}(t)\|_V^2 \leq C_0.\]

(2.8)

Therefore
\[r^{(m)}, \partial_t r^{(m)}, \partial_t^2 r^{(m)} \in L^\infty(-T, T; V), \quad \partial_t^2 r^{(m)} \in L^\infty(-T, T; [L^2(\Omega)]^6)\]

are bounded. It follows that we can extract a subsequence of \(\{r^{(m)}\}\), still denoted by \(\{r^{(m)}\}\), such that
\[r^{(m)} \to r, \quad \partial_t r^{(m)} \to \partial_t r \quad \text{weak-}^* \text{ in } L^\infty(-T, T; V)\]

and
\[\partial_t^2 r^{(m)} \to \partial_t^2 r \quad \text{weak-}^* \text{ in } L^\infty(-T, T; [L^2(\Omega)]^6).\]

Since \(\{\psi^{(m)}\}\) is dense in V, we have, for any \(v \in V\),
\[(A\partial_t^2 r^{(m)}, v) \to (A\partial_t^2 r, v) \quad \text{weak-}^* \text{ in } L^\infty(-T, T),\]
\[(B\partial_t r^{(m)}, v) \to (B\partial_t r, v) \quad \text{weak-}^* \text{ in } L^\infty(-T, T),\]
\[
\mathcal{B}(r^{(m)}, v) \to \mathcal{B}(r^{*}, v) \quad \text{weak-}^* \text{ in } L^\infty(-T, T).
\]

The existence is completed by letting \(m \to \infty\) in (2.3). The uniqueness is obvious from (2.6) and (2.8) by choosing \(F = 0\).

3. A Carleman estimate for the electroseismic model

To derive a Carleman estimate for a system of equations, the usual process consists in diagonalizing the system and then in applying a Carleman estimate for each scalar equation that composes the diagonalized system [14]. We first recall a known Carleman estimate for the scalar wave equation [15, 14]. For fixed constants \(c > 0\) and \(m > c\) define the set \(\mathcal{C}_0\) by
\[\mathcal{C}_0 := \{c \in C^2(\overline{\Omega}); \quad c_0 < c; \quad \|c\|_{C^2(\overline{\Omega})} \leq m\},\]

(3.1)

and let \(\mathcal{C}\) be the set of functions in \(\mathcal{C}_0\), satisfying in addition the inequality
\[\frac{\nabla c \cdot (x - x_\ast)}{2c} < 1 - c_0, \quad \text{for all } x \in \overline{\Omega},\]

(3.2)

where \(c_0 \in (0, 1)\) is a fixed constant, and \(x_\ast \in \mathbb{R}^3 \setminus \overline{\Omega}\) is a fixed point.

**Lemma 3.1.** Assume \(c \in \mathcal{C}\). Then there exist constants \(T > 0, \xi = c, \theta > 0\) such that the function \(\varphi = e^{\theta \psi}\) given by \(\psi = |x - x_\ast|^2 - \xi|t|^2\) satisfies \(\varphi(x, T) = \varphi(x, -T) < 1, \varphi(x, 0) \geq 1\) and
\[\int_Q e^{2\tau \varphi}(\tau^3|u|^2 + \tau|\nabla x, u|^2) \leq C_0 \int_Q e^{2\tau \varphi}|f|^2,\]

where \(Q = \mathbb{R}^3 \setminus \overline{\Omega}\).
for all $\tau$ large than a positive constant $\tau_0$ and for any $u \in C^2_0(\Omega)$ that solves
\[
\partial^2_{\tau} u - c(x) \Delta u = f.
\]
The constants $T$, $\zeta$, $\theta$, and $C_0$ only depend on $\mathcal{C}$, $x_*$ and $\Omega$. The notation $| \cdot |^2$ means the sum of the square of all the components of vectors or matrices.

**Remark 1.** For any $\epsilon > 0$ sufficiently small, there exists a constant $\delta$ such that $\varphi(x, t) > 1 - \epsilon$ for $|t| < \delta$ and $\varphi(x, t) < 1 - 2\epsilon$ for $t > T - \delta$ or $t < -T + \delta$. We denote $\varphi_0(x) = \varphi(x, 0)$, $\Phi = \max_{(x, t) \in \mathcal{Q}} \varphi$.

For the Maxwell equations with $\sigma = 0$, Carleman estimates can be found, for example, in [2, 14]. The arguments in these references easily generalize to the case $\sigma \neq 0$.

**Lemma 3.2.** Assume that $\alpha, \beta \in C^2(\Omega)$ and $\gamma \in C^1(\Omega)$, such that $\alpha, \beta > \alpha_0 > 0$ and $\gamma \geq 0$. Assume additionally that the wave speed $c := \alpha \beta$ belongs to $\mathcal{C}$. Then the following inequality holds
\[
\int_0^2 e^{2\tau \varphi}(\tau^3 |D|^2 + \tau |\nabla_x D|^2) \leq C_0 \int_0^2 e^{2\tau \varphi}(|D|^2 + |\nabla_x D|^2).
\]
for all $\tau$ larger than a positive constant $\tau_0$ and for any $D, B \in C^2_0(\Omega)$ that solve
\[
\begin{aligned}
\partial_\tau D - \text{curl}(\alpha B) + \gamma D &= J_1, \\
\partial_\tau B + \text{curl}(\beta D) &= J_2, \\
\text{div} D = \text{div} B &= 0.
\end{aligned}
\tag{3.3}
\]
The constants $T$, $\zeta$ and $\theta$ are as in lemma 3.1. The constants $\tau_0$ and $C_0$ only depend on $\mathcal{C}$, $x_*$, $\|\gamma\|_{C^{1}(\Omega)}$, $\|D\|_{C^{2}(\Omega)}$ and $\|B\|_{C^{2}(\Omega)}$.

**Proof.** By substitution, the system can be transformed into the following two equations
\[
\begin{aligned}
\partial^2_{\tau} D - \alpha \beta \Delta D &= \partial_\tau J_1 + \text{curl}(\alpha J_2) - \mathcal{R}_1, \\
\partial^2_{\tau} B - \alpha \beta \Delta B &= \partial_\tau J_2 - \text{curl}(\beta J_1) - \mathcal{R}_2,
\end{aligned}
\]
where
\[
\begin{aligned}
\mathcal{R}_1 &= \nabla(\alpha \beta) \times \text{curl} D + \text{curl}(\alpha \nabla \beta \times D) + \gamma \partial_\tau D, \\
\mathcal{R}_2 &= \nabla(\alpha \beta) \times \text{curl} B + \text{curl}(\beta \nabla \alpha \times B) - \text{curl}(\beta \gamma D).
\end{aligned}
\]
Applying lemma 3.1 to each component of the equations, we have
\[
\int_0^2 e^{2\tau \varphi}(\tau^3 |D|^2 + \tau |\nabla_x D|^2) \leq C_0 \int_0^2 e^{2\tau \varphi}(F^2 + |D|^2 + |\nabla_x D|^2),
\]
\[
\int_0^2 e^{2\tau \varphi}(\tau^3 |B|^2 + \tau |\nabla_x B|^2) \leq C_0 \int_0^2 e^{2\tau \varphi}(F^2 + |D|^2 + |\nabla_x D|^2 + |B|^2 + |\nabla_x B|^2),
\]
where $F = |J_1|^2 + |J_2|^2 + |\nabla_x J_1|^2 + |\nabla_x J_2|^2$. Adding these two inequalities and taking $\tau$ large enough to absorb the right hand side terms completes the proof. \hfill \blacksquare
Before deriving a Carleman estimate for the Biot equations, we study the property of the associated matrix of material coefficients. Define
\[
\rho_0 = \rho p_e - \rho^2, \quad \mathbf{a} = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} = \begin{pmatrix} \rho_0 & \rho_f \\ 0 & P_e \end{pmatrix}^{-1} \begin{pmatrix} \lambda + G - \frac{\rho_0}{\rho_e} C & C \\ C - \frac{\rho_0}{\rho_e} M & M \end{pmatrix}, \quad c = \frac{\rho_0}{\rho_0} G.
\] (3.4)

From the positive definite of the matrices (1.11), we have \(\rho_0 > 0\). Let us denote
\[
\tilde{\mathbf{a}} = \begin{pmatrix} c + a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}
\] (3.5)
which can be expanded into
\[
\tilde{\mathbf{a}} = \begin{pmatrix} \frac{\rho_0 (\lambda + 2G) - 2\rho_0 \frac{\rho_0}{\rho_e} C + \frac{\rho_0}{\rho_0} M}{\rho_e} & \frac{\rho_0 C - \rho_0 M}{\rho_0} \\ \frac{1}{\rho_0} C - \frac{\rho_0}{\rho_e} M & \frac{1}{\rho_0} M \end{pmatrix}.
\]

The two eigenvalues of \(\tilde{\mathbf{a}}\) are
\[
\frac{(c + a_{11} + a_{22}) \pm \sqrt{(c + a_{11} - a_{22})^2 + 4a_{12}a_{21}}}{2}.
\]
Since
\[
a_{12}a_{21} = \frac{1}{\rho_0} (C - \frac{\rho_0}{\rho_e} M)^2 \geq 0,
\]
\(\tilde{\mathbf{a}}\) has two real eigenvalues. The determinant of \(\tilde{\mathbf{a}}\) is
\[
\det \tilde{\mathbf{a}} = \frac{1}{\rho_0} (\lambda + 2G) + \frac{2}{\rho_e} M - 2\frac{\rho_0}{\rho_e} C - \frac{1}{\rho_0} (C - \frac{\rho_0}{\rho_e} M)^2 = \frac{1}{\rho_0} (\lambda M - C^2 + 2GM) > 0,
\]
and its trace is
\[
\text{tr} \tilde{\mathbf{a}} = \frac{1}{\rho_0} \left( \rho_e (\lambda + 2G) + \rho M - 2\rho_f C \right) \geq \frac{\rho_f}{\rho_0} (\lambda + 2G + M - 2C).
\]

From the positive definite of the matrices (1.11), we have \((\lambda + M)^2 \geq 4\lambda M > 4C^2\) and hence \(\text{tr} \tilde{\mathbf{a}} > 0\). Therefore \(\tilde{\mathbf{a}}\) is similar to a diagonal matrix and it has two positive eigenvalues.

In the following, we will derive a Carleman estimate for the Biot system (1.3)–(1.6). The idea is similar as with the Maxwell or the elastic system. We emphasize that the results from [3] do not apply directly to our Biot system, which is different from the one treated in that reference due to the presence of the term \(\partial_t \mathbf{w}\). We will explain in detail the difference in the proof of the following lemma.

**Lemma 3.3.** Assume that all the parameters in the Biot equations are in \(C^3(\overline{\Omega})\). Assume that \(c = \frac{\rho_0}{\rho_0} G\) and two eigenvalues of the matrix \(\tilde{\mathbf{a}}\) given by (3.5) belong to \(\mathcal{C}\). Then there exists a constant \(C_0 > 0\) such that
\[
\int_Q e^{2\tau \sigma} \left( \tau^3 (|\mathbf{u}|^2 + |\text{div} \mathbf{u}|^2 + |\text{div} \mathbf{w}|^2 + |\text{curl} \mathbf{u}|^2) \\
+ \tau \left( |\nabla_{x_1} \mathbf{u}|^2 + |\nabla_{x_1} (\text{div} \mathbf{u})|^2 + |\nabla_{x_1} (\text{div} \mathbf{w})|^2 + |\nabla_{x_1} (\text{curl} \mathbf{u})|^2 \right) \right)
\leq C_0 \int_Q e^{2\tau \sigma} (|\mathbf{F}_1|^2 + |\mathbf{F}_2|^2 + |\mathbf{D}|^2 + |\nabla \mathbf{F}_1|^2 + |\nabla \mathbf{F}_2|^2 + |\nabla \mathbf{D}|^2),
\]
for all $\tau$ larger than a positive constant $\tau_0$ and for any $u, w \in C_0^1(\Omega)$ that solve

\[
\begin{align*}
\rho \partial_t^2 u + \rho_f \partial_t^2 w - \text{div} \ \tau &= F_1, \\
\rho_f \partial_t^2 u + \rho_e \partial_t^2 w + \nabla p + \frac{\eta}{\kappa} \partial_t w - \xi D &= F_2, \\
(\lambda \text{div} u + C \text{div} w) I + G(\nabla u + \nabla u^T) &= \tau, \\
C \text{div} u + M \text{div} w &= -p.
\end{align*}
\] (3.6)

The constants $C_0$ and $\tau_0$ depend on the parameters of the Biot system, $\|u\|_{C^1(\Omega)}$, $\|u\|_{C^1(\Omega)}$, and $\|w\|_{C^1(\Omega)}$.

**Proof.** Let $v = w + \frac{\rho_f}{\rho_e} u$ and replace $w$ by $u, v$ in the above system, to obtain

\[
\begin{align*}
\frac{\rho_0}{\rho_e} \partial_t^2 u + \eta \partial_t^2 v - \text{div} \ \tau &= F_1, \\
\rho_e \partial_t^2 v + \nabla p + \frac{\eta}{\kappa} \left( \partial_t v - \frac{\rho_f}{\rho_e} \partial_t u \right) - \xi D &= F_2, \\
\left( \lambda - C \frac{\rho_f}{\rho_e} \right) \text{div} u + C \text{div} v - C u \cdot \frac{\rho_f}{\rho_e} = \tau, \\
\left( C - M \frac{\rho_f}{\rho_e} \right) \text{div} u - M \text{div} v &= -p.
\end{align*}
\]

where $I$ is the identity matrix of order 3. After substitution of $\tau$ and $p$, we have

\[
\begin{align*}
\frac{\rho_0}{\rho_e} \partial_t^2 u + \rho_f \partial_t^2 v - \text{div} \Delta u - \left( \lambda + G - \frac{\rho_f}{\rho_e} C \right) \nabla \text{div} u &= \text{C} \nabla \text{div} v = F_1 + \mathcal{P}_1, \\
\rho_e \partial_t^2 v + \frac{\eta}{\kappa} \partial_t v - \left( C - \frac{\rho_f}{\rho_e} M \right) \nabla \text{div} u - M \nabla \text{div} v &= F_2 + \mathcal{P}_2,
\end{align*}
\] (3.7) (3.8)

where

\[
\begin{align*}
\mathcal{P}_1 &= (\text{div} u) \nabla \left( \lambda - \frac{\rho_f}{\rho_e} M \right) + (\text{div} v) \nabla C + (\nabla u + \nabla u^T) \cdot \nabla G - \nabla \left( C u \cdot \frac{\rho_f}{\rho_e} \right), \\
\mathcal{P}_2 &= (\text{div} u) \nabla \left( C - \frac{\rho_f}{\rho_e} M \right) + (\text{div} v) \nabla M - \nabla \left( M u \cdot \frac{\rho_f}{\rho_e} \right) + \frac{\rho_f \eta}{\rho_e \kappa} \partial_t u + \xi D.
\end{align*}
\]

Set $r = \text{div} u, s = \text{div} v, m = \text{curl} u, n = \text{curl} v$ and

\[
K = \begin{pmatrix}
\frac{\rho_0}{\rho_e} I & \frac{\rho_f}{\rho_e} I \\
0 & \frac{\rho_f}{\rho_e} I
\end{pmatrix}^{-1}.
\]

We multiply the equation system (3.7) and (3.8) by $K$ to obtain

\[
\begin{align*}
\partial_t^2 u - c \Delta u - \frac{\eta \eta}{\rho_e \kappa} \partial_t v - a_{11} \nabla \text{div} u - a_{12} \nabla \text{div} v &= G_1 + \mathcal{P}_3, \\
\partial_t^2 v + \frac{\eta}{\rho_e \kappa} \partial_t v - a_{21} \nabla \text{div} u - a_{22} \nabla \text{div} v &= G_2 + \mathcal{P}_4,
\end{align*}
\] (3.9) (3.10)
where
\[ c = \frac{\rho_0 G}{\rho_0} \begin{pmatrix} G_1 \\ G_2 \end{pmatrix} = K \begin{pmatrix} F_1 \\ F_2 \end{pmatrix}, \quad \begin{pmatrix} P_3 \\ P_4 \end{pmatrix} = K \begin{pmatrix} P_1 \\ P_2 \end{pmatrix} \]

and \( a \) is given by (3.4). Note that \( P_3 \) and \( P_4 \) are composed of \( r, s, u, \nabla_x u, D \). The equations (3.9) and (3.10) can be rewritten as
\[
\begin{align*}
\partial_t^2 u - c\Delta u &= G_1 + \mathcal{D}_1, \quad (3.11) \\
\partial_t^2 v + \frac{\eta}{\rho_0 c} \partial_t \nu &= G_2 + \mathcal{D}_2, \quad (3.12)
\end{align*}
\]

where \( \mathcal{D}_1 \) and \( \mathcal{D}_2 \) are first order differential operators that involve \( r, s, u, D \). The operator \( \mathcal{D}_1 \) also contains \( \partial_t \nu \). Taking the divergence on both sides of the equations (3.9) and (3.10) and with the help of the equality \( \Delta u = \nabla r - \nabla \nu \), we have
\[
\begin{align*}
\partial_t^2 r - (c + a_{11}) \Delta r - a_{12} \Delta s &= \text{div} G_1 + \mathcal{F}_1, \quad (3.13) \\
\partial_t^2 s - a_{21} \Delta r - a_{22} \Delta s &= \text{div} G_2 + \mathcal{F}_2, \quad (3.14)
\end{align*}
\]

where \( \mathcal{F}_1 \) and \( \mathcal{F}_2 \) are first order differential operators of \( r, s, D, u, m \). Besides, they also contain \( \partial_t \nu \). Taking the curl on both sides of the equations (3.9) and (3.10) gives
\[
\begin{align*}
\partial_t^2 m - c\Delta m &= \text{curl} G_1 + \mathcal{F}_1, \quad (3.15) \\
\partial_t^2 n + \frac{\eta}{\rho_0 c} \partial_t \nu &= \text{curl} G_2 + \mathcal{F}_2, \quad (3.16)
\end{align*}
\]

where \( \mathcal{F}_1 \) and \( \mathcal{F}_2 \) are first order differential operators of \( r, s, D, u, m \). The expression of \( \mathcal{F}_1 \) also involves the terms \( \partial_t \nu \), \( \partial_t \nu \) and \( \partial_t \nu \) also contains \( \partial_t \nu \).

We emphasize that the presence of the terms \( \partial_t \nu \) and \( \partial_t \nu \) in the right-hand sides \( \mathcal{D}_1 \) and \( \mathcal{F}_1 \) prevents us from using the Carleman estimate in [3] directly. The control of \( \mathcal{D}_1 \) and \( \mathcal{F}_1 \) requires an estimation of \( \partial_t \nu \) and \( \partial_t \nu \). This is actually why we change the variables from \( w \) to \( v \). Applying lemma 3.1 to (3.11) and (3.15) yield
\[
\begin{align*}
\int_Q e^{2\tau \psi} \left( \tau^2 |u|^2 + \tau|\nabla_x u|^2 \right) \\
&\leq C_0 \int_Q e^{2\tau \psi} \left( |G_1|^2 + |D|^2 + |r|^2 + |\nabla_x r|^2 + |s|^2 + |\nabla_x s|^2 + |\nabla \nu|^2 \right). \quad (3.17)
\end{align*}
\]

Further, applying lemma 2.1 from [3] to (3.13) and (3.14), we have
\[
\begin{align*}
\int_Q e^{2\tau \psi} \left( \tau^3 |m|^2 + \tau|\nabla_x m|^2 \right) \\
&\leq C_0 \int_Q e^{2\tau \psi} \left( |\text{curl} G_1|^2 + |D|^2 + |\nabla D|^2 + |u|^2 + |\nabla_x u|^2 \\
&+ |r|^2 + |\nabla_x r|^2 + |s|^2 + |\nabla_x s|^2 + |\partial_t \nu|^2 + |\partial_t \nu|^2 \right). \quad (3.18)
\end{align*}
\]
\[
\int_Q \varepsilon^{2\varphi}\left(\rho^2(|v|^2 + |s|^2) + \tau (|\nabla_x r|^2 + |\nabla_x s|^2)\right)
\leq C_0 \int_Q \varepsilon^{2\varphi}\left(|\nabla G_1|^2 + |\nabla G_2|^2 + |D|^2 + |\nabla D|^2\right.
+ |u|^2 + |\nabla_x u|^2 + |m|^2 + |\nabla_x m|^2 + |\partial_\nu|^2). \tag{3.19}
\]

Combining (3.17)–(3.19) shows that
\[
\int_Q \varepsilon^{2\varphi}\left(\rho^2(|v|^2 + |s|^2) + |u|^2 + |m|^2) + \tau (|\nabla_x r|^2 + |\nabla_x s|^2) + |\nabla_x u|^2 + |\nabla_x m|^2)\right)
\leq C_0 \int_Q \varepsilon^{2\varphi}\left(|G_1|^2 + |\nabla G_1|^2 + |G_2|^2 + |\nabla G_2|^2 + |D|^2 + |\nabla D|^2 + |\partial_\nu|^2 + |\partial_n|^2\right). \tag{3.20}
\]

Next, we estimate \(\partial_\nu v\) and \(\partial_\nu n\). Since the differential operator involved in (3.12) acts only on the variable \(t\), we are able to derive the explicit expression of \(\partial_\nu v\) and obtain
\[
\partial_\nu v = \left(\int_0^1 \varepsilon^\varphi \frac{\partial}{\partial s} (G_2 + \mathcal{B}_2) ds\right) e^{-\int_0^1 \frac{\partial}{\partial s} |G_2 + \mathcal{B}_2| ds}. \]

Multiplying both sides by \(e^{\tau \varphi}\), and using the fact that \(e^{\tau \varphi(x,t)} \leq e^{\tau \varphi(x,t)}\) for all \(|s| \leq |t|\), we get
\[
|\partial_\nu v| e^{\tau \varphi} \leq \left(\int_0^1 \varepsilon^\varphi \frac{\partial}{\partial s} (G_2 + \mathcal{B}_2) ds\right) e^{-\int_0^1 \frac{\partial}{\partial s} |G_2 + \mathcal{B}_2| ds}. \]

Taking the square of the previous relation, integrating over \(Q\), and using the Hölder inequality, we finally find
\[
\int_Q \varepsilon^{2\varphi}|\partial_\nu v|^2 \leq C_0 \int_Q \varepsilon^{2\varphi} \left(|G_2|^2 + |\mathcal{B}_2|^2\right). \tag{3.21}
\]

Proceeding similarly for \(\partial_\nu n\), shows that
\[
\int_Q \varepsilon^{2\varphi}|\partial_\nu n|^2 \leq C_0 \int_Q \varepsilon^{2\varphi} \left(|\text{curl } G_2|^2 + |\mathcal{B}_2|^2\right). \tag{3.22}
\]

Therefore \(\partial_\nu v\) and \(\partial_\nu n\) are bounded by \(r, s, D, u, m\) and their first order derivatives. In fact, multiplying by the weight \(\varepsilon^{2\varphi}\) and integrating over \(Q\), deteriorates the stability in determining \(\partial_\nu v\) and \(\partial_\nu n\) from \(r, s, D, u, m\) and their first order derivatives.

Considering now the obtained inequalities (3.21) and (3.22), the estimate (3.20) becomes
\[
\int_Q \varepsilon^{2\varphi}\left(\rho^2(|v|^2 + |s|^2) + |u|^2 + |m|^2 + \tau (|\nabla_x r|^2 + |\nabla_x s|^2 + |\nabla_x u|^2 + |\nabla_x m|^2)\right)
\leq C_0 \int_Q \varepsilon^{2\varphi}\left(|G_1|^2 + |\nabla G_1|^2 + |G_2|^2 + |\nabla G_2|^2 + |D|^2 + |\nabla D|^2 + |\partial_\nu|^2 + |\partial_n|^2\right). \tag{3.23}
\]

The lemma is completed by taking \(\tau\) large enough to control the zero and first order terms of \(r, s, u, m\) on the right hand side of (3.23) and the relations between \(w, G_1, G_2\) and \(u, v, F_1, F_2\). \(\blacksquare\)
Let
\[ \mathcal{C}_0 := \left\{ (\alpha, \beta, \gamma, \xi) \in (C^2(\Omega))^3 \times (C^1(\Omega))^3 \mid \alpha, \beta \in C(\Omega), \gamma, \xi \in C(\Omega), \alpha > \alpha_0 > 0; \gamma, \xi \geq 0; \alpha, \beta \in \Re \right\}. \]
(3.24)

Combining now lemmas 3.2 and 3.3, yields a Carleman estimate for the electroseismic system.

**Theorem 3.1.** Assume that all the parameters in the electroseismic system satisfy the hypotheses of lemmas 3.2 and 3.3. Assume that \((\alpha, \beta, \gamma, \xi) \in \mathcal{C}_0\). Then, there exists a constant \(C_0\) such that
\[
\int_{\Omega} e^{2\tau \varphi} \left( \tau^3 (|D|^2 + |B|^2 + |u|^2 + |\text{div} u|^2 + |\text{div} w|^2 + |\text{curl} u|^2) \\
+ \tau (|\nabla_x D|^2 + |\nabla_x B|^2 + |\nabla_x u|^2 + |\nabla_x (\text{div} u)|^2 + |\nabla_x (\text{curl} u)|^2) \right) \\
\leq C_0 \int_{\Omega} e^{2\tau \varphi} (|F|^2 + |J|^2 + |\text{div} F|^2 + |\text{curl} F|^2 + |\text{div} J|^2 + |\text{curl} J|^2),
\]
for all \(\tau\) larger than a positive constant \(\tau_0\) and for any \(D, B \in C^2_0(\Omega), u, w \in C^1_0(\Omega)\) that solve respectively (3.3) and (3.6). The constants \(\tau_0\) and \(C_0\) only depend on \(C, x, \|D\|_{C^1(\Omega)}, \|B\|_{C^1(\Omega)}, \|u\|_{C^1(\Omega)}, \|w\|_{C^1(\Omega)}\).

4. The inverse problem

We now state our main result: a stability theorem for the inverse problem. For \(\mathfrak{M} > 0\) define the set of functions \(\mathcal{C}\) by
\[ \mathcal{C} := \left\{ (\alpha, \beta, \gamma, \xi) \in \mathcal{C}_0 : \|B\|_{C^1(\Omega)}, \|D\|_{C^1(\Omega)}, \|u\|_{C^1(\Omega)}, \|w\|_{C^1(\Omega)} \leq \mathfrak{M} \right\}. \] (4.1)

**Theorem 4.1.** Let \((\alpha_1, \beta_1, \gamma_1, \xi_1)\) and \((\alpha_2, \beta_2, \gamma_2, \xi_2)\) denote two sets of parameters in \(\mathcal{C}\). Assume that these two sets of parameters coincide in a set \(\Sigma\) where \(\omega \subset \Omega\) is a neighborhood of \(\partial \Omega\). Let \((D_0^{(1)}, B_0^{(1)})\) and \((D_0^{(2)}, B_0^{(2)})\) denote two sets of initial values, such that the matrix \(M(x)\) defined by
\[
M(x) = \begin{pmatrix}
0 & e_1 \times B_0^{(1)} & e_2 \times B_0^{(1)} & e_3 \times B_0^{(1)} & 0 & 0 & -D_0^{(1)} \\
0 & 0 & 0 & 0 & -e_1 \times D_0^{(1)} & -e_2 \times D_0^{(1)} & -e_3 \times D_0^{(1)} \\
e_1 \times B_0^{(2)} & e_2 \times B_0^{(2)} & e_3 \times B_0^{(2)} & -D_0^{(2)} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -e_1 \times D_0^{(2)} & -e_2 \times D_0^{(2)} & -e_3 \times D_0^{(2)}
\end{pmatrix}
\]
has a nonzero \(7 \times 7\) minor on \(\Omega\). Here
\[ e_1 = (1 \ 0 \ 0), \ e_2 = (0 \ 1 \ 0), \ e_3 = (0 \ 0 \ 1) \].

Assume the following regularity
\[ D_k^{(j)}, B_k^{(j)} \in C^0(\Omega), \ u_k^{(j)}, w_k^{(j)} \in C^0(\Omega) \] \(j = 1, 2,\)

of the solutions to the system (1.1)–(1.7), where \(v_k^{(j)}\) represents the field \(v\) corresponding to the parameters \((\alpha_k, \beta_k, \gamma_k, \xi_k)\) and the \(j\)th initial values. Then, there exist constants \(C_0\) and \(c_0\in (0, 1)\) such that
\[ \int_{\Omega} \Lambda \leq C_0(\mathcal{D}^{(1)} + \mathcal{D}^{(2)})^\alpha \]

where

\[
\Lambda = \tilde{\Lambda} + |\xi|^2 + |\nabla \xi|^2,
\]

\[
\tilde{\Lambda} = |\alpha|^2 + |\beta|^2 + |\gamma|^2 + |\nabla \alpha|^2 + |\nabla \beta|^2 + |\nabla \gamma|^2 + |\nabla \nabla \alpha|^2 + |\nabla \nabla \beta|^2.
\]

\[
\mathcal{D}^{(j)} = \|D^{(j)}\|^2_{\dot{H}^1(\Omega_\omega)} + \|B^{(j)}\|^2_{\dot{H}^1(\Omega_\omega)} + \|\mathbf{u}^{(j)}\|^2_{\dot{H}^1(\Omega_\omega)} + \|w^{(j)}\|^2_{\dot{H}^1(\Omega_\omega)}.
\]

and

\[
\alpha = \alpha_2 - \alpha_1, \quad \beta = \beta_2 - \beta_1, \quad \gamma = \gamma_2 - \gamma_1, \quad \xi = \xi_2 - \xi_1,
\]

\[
\mathbf{D} = \mathbf{D}_2 - \mathbf{D}_1, \quad \mathbf{B} = \mathbf{B}_2 - \mathbf{B}_1, \quad \mathbf{u} = \mathbf{u}_2 - \mathbf{u}_1, \quad w = w_2 - w_1.
\]

The constants \(c_0\) and \(C_0\) depend on \(\mathbf{C}, \omega, \mathbf{B}_0^{(j)}\) and \(\mathbf{D}_0^{(j)}\).

**Remark 2.** If we choose \(\mathbf{B}_0^{(1)} = \mathbf{e}_1, \mathbf{D}_0^{(1)} = \mathbf{e}_2, \mathbf{B}_0^{(2)} = \mathbf{D}_0^{(2)} = \mathbf{e}_3\), the matrix \(\mathbf{M}(\mathbf{x})\) formed by rows \((2, 3, 4, 5, 8, 9, 10)\) and by all the columns of \(\mathbf{M}(\mathbf{x})\) is nonsingular. The assumption on the regularity of the solutions is required to apply the Carleman estimate to the electroseismic system. Finally for our inverse problem, we assume near boundary measurements and use Carleman estimates with compact support functions. For partial boundary measurement we need to construct different Carleman estimates. This could be done by following the works of Imanuvilov and Yamamoto for Lame systems [4, 13, 23].

**Remark 3.** From the structure of \(\mathbf{M}(\mathbf{x})\), the existence of a nonzero \(7 \times 7\) minor indicates that there exists a positive constant \(c_\ast\) such that \(|\mathbf{B}_0^{(1)}|^2 + |\mathbf{B}_0^{(2)}|^2 > c_\ast\) and \(|\mathbf{D}_0^{(1)}|^2 + |\mathbf{D}_0^{(2)}|^2 > c_\ast\).

We prove theorem 4.1 in 3 steps in the following subsections.

### 4.1. A modified Carleman estimate

Since our Carleman estimate is applicable for functions compactly supported in \(\Omega\), in the first step we cut off the functions. The near boundary part corresponds to the measurements and the inner part can be bounded by the Carleman estimate. The fields \((\mathbf{D}, \mathbf{B}, \mathbf{u}, w)\) satisfy the following system of equations in \(\Omega\)

\[
\partial_t \mathbf{D} - \text{curl} (\alpha_2 \mathbf{B}) + \gamma_2 \mathbf{D} = \text{curl} (\alpha \mathbf{B}_1) - \gamma \mathbf{D}_1, \tag{4.2}
\]

\[
\partial_t \mathbf{B} + \text{curl} (\beta_2 \mathbf{D}) = -\text{curl} (\beta \mathbf{D}_1), \tag{4.3}
\]

\[
\rho \partial_t^2 \mathbf{u} + \rho \nu \partial_t^2 \mathbf{w} - \text{div} \mathbf{\tau} = \mathbf{0}, \tag{4.4}
\]

\[
\rho \nu \partial_t^2 \mathbf{u} + \rho \nu \partial_t^2 \mathbf{w} + \nabla p + \frac{2}{\kappa} \partial_t \mathbf{w} - \xi \mathbf{D} = \xi \mathbf{D}_1, \tag{4.5}
\]

with zero initial conditions. Define \(\chi(\mathbf{x}, t) = \chi_1(\mathbf{x}) \chi_2(t)\) with \(\chi_1 \in C^\infty_0(\Omega), \chi_2 \in C^\infty_0(-T, T), 0 \leq \chi_1, \chi_2 \leq 1\) and

\[
\chi_1 = 1 \text{ in } \Omega_\omega, \quad \chi_2 = 1 \text{ in } [-T + \delta, T - \delta],
\]
where $\delta$ is chosen as in remark 1 and $\Omega_0 = \Omega \setminus \omega$. Denote $\tilde{D} = \chi D, \tilde{B} = \chi B, \tilde{u} = \chi u, \tilde{w} = \chi w$. Then

$$
\partial_t \tilde{D} - \text{curl} (\alpha_2 \tilde{B}) + \gamma_2 \tilde{D} = \chi (\text{curl} (\alpha B) - \gamma D) + P_1,
$$

(4.6)

$$
\partial_t \tilde{B} + \text{curl} (\beta_2 \tilde{D}) = -\chi \text{curl}(\beta D) + P_2,
$$

(4.7)

$$
\rho \partial_t^2 \tilde{u} + \rho \partial_t^2 \tilde{w} - \nabla \tilde{p} + \eta \partial_t \tilde{w} - \xi_2 \tilde{D} = \chi \xi D + P_4,
$$

(4.9)

where

$$
P_1 = (\partial_t \chi) D - \nabla \chi \times (\alpha_2 B), \quad P_2 = (\partial_t \chi) B + \nabla \chi \times (\beta_2 D),
$$

$P_3, P_4$ first order differential operators in $u, w$. Let us note that $P_1, P_2, P_3, P_4$ vanish in $Q_0(\delta) = \Omega_0 \times (-T + \delta, T - \delta)$. Applying theorem 3.1 to (4.6)–(4.9), we have

$$
\int_Q e^{2\tau \varphi} \left( \tau^3 (|\tilde{D}|^2 + |\tilde{B}|^2 + |\tilde{u}|^2) + \tau (|\nabla_x \tilde{D}|^2 + |\nabla_x \tilde{B}|^2 + |\nabla_x \tilde{u}|^2) \right) \leq C_0 \int_Q e^{2\tau \varphi} \Lambda + C_0 \int_{Q_\delta} e^{2\tau \varphi} \Pi + C_0 \int_{\Omega \times (-T + \delta, T - \delta)} e^{2\tau \varphi} \Pi,
$$

(4.10)

where

$$
\Pi = |D|^2 + |B|^2 + |u|^2 + |w|^2 + |\nabla_x D|^2 + |\nabla_x B|^2 + |\nabla_x u|^2 + |\nabla_x w|^2 + |\nabla \nabla_x u|^2 + |\nabla \nabla_x w|^2.
$$

Then from (4.10) and remark 1, we have

$$
\int_{Q_0(\delta)} e^{2\tau \varphi} \left( \tau^3 (|\partial_t D|^2 + |\partial_t B|^2 + |\partial_t u|^2) + \tau (|\nabla_x \partial_t D|^2 + |\nabla_x \partial_t B|^2 + |\nabla_x \partial_t u|^2) \right) \leq C_0 \int_Q e^{2\tau \varphi} \Lambda + C_0 e^{2\tau \varphi} \partial_t \Omega + C_0 e^{2\tau (1-2\epsilon)},
$$

(4.11)

Similarly, taking the derivative with respect to $t$ on both sides of (4.2)–(4.5) yields the following inequalities

$$
\int_{Q_0(\delta)} e^{2\tau \varphi} \left( \tau^3 (|\partial_t D|^2 + |\partial_t B|^2 + |\partial_t u|^2) + \tau (|\nabla_x \partial_t D|^2 + |\nabla_x \partial_t B|^2 + |\nabla_x \partial_t u|^2) \right) \leq C_0 \int_Q e^{2\tau \varphi} \Lambda + C_0 e^{2\tau \varphi} \partial_t \Omega + C_0 e^{2\tau (1-2\epsilon)},
$$

(4.12)

for $j = 1, 2, 3$.

### 4.2. Bounding parameters by initial values

Letting $t$ goes to 0 in (4.2)–(4.5) shows that

$$
\partial_t D(x, 0) = \text{curl}(\alpha B_0) - \gamma D_0,
$$

(4.13)

$$
\partial_t B(x, 0) = -\text{curl}(\beta D_0),
$$

(4.14)

$$
\rho \partial_t^2 u(x, 0) + \rho \partial_t^2 w(x, 0) = 0,
$$

(4.15)
\[ \rho_1 \partial_t^2 \mathbf{u}(\mathbf{x}, 0) + \rho_0 \partial_x^2 \mathbf{w}(\mathbf{x}, 0) = \zeta \mathbf{D}_0. \]  

(4.16)

Expanding the curl in (4.13) and (4.14) yields
\[ \nabla \alpha \times \mathbf{B}_0 + \alpha \text{curl} \mathbf{B}_0 - \gamma \mathbf{D}_0 = \partial_t \mathbf{D}(\mathbf{x}, 0), \]
\[ - \nabla \beta \times \mathbf{D}_0 - \beta \text{curl} \mathbf{D}_0 = \partial_t \mathbf{B}(\mathbf{x}, 0). \]

Substituting (4.15) into (4.16) to eliminate \( \mathbf{w} \) gives
\[ \mathbf{D}_0 \xi = -\rho_1 \partial_t^2 \mathbf{u}(\mathbf{x}, 0), \]
where \( \rho_1 = \frac{\rho_0}{\rho_1} \). Considering the two sets of initial values, we have
\[ \mathbf{M}(\mathbf{x}) \begin{pmatrix} \nabla \alpha \\ \gamma \\ \nabla \beta \end{pmatrix} = \mathbf{N}(\mathbf{x}) \begin{pmatrix} \alpha \\ \beta \end{pmatrix} + \mathbf{b}(\mathbf{x}), \]

(4.17)

\[ \mathbf{D}_0^{(j)} \xi = -\rho_1 \partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0), \]

(4.18)

where
\[ \mathbf{M}(\mathbf{x}) = \begin{pmatrix} -\text{curl} \mathbf{B}_0^{(1)} & 0 & -\text{curl} \mathbf{B}_0^{(2)} \\ 0 & \text{curl} \mathbf{D}_0^{(1)} & 0 \\ -\text{curl} \mathbf{B}_0^{(2)} & 0 & \text{curl} \mathbf{D}_0^{(2)} \end{pmatrix}, \quad \mathbf{N}(\mathbf{x}) = \begin{pmatrix} \partial_t \mathbf{D}^{(1)}(\mathbf{x}, 0) \\ \partial_t \mathbf{B}^{(1)}(\mathbf{x}, 0) \\ \partial_t \mathbf{D}^{(2)}(\mathbf{x}, 0) \\ \partial_t \mathbf{B}^{(2)}(\mathbf{x}, 0) \end{pmatrix}. \]

Since \( \mathbf{M}(\mathbf{x}) \) has a 7 \times 7 nonzero minor, we have
\[ |\nabla \alpha|^2 + |\nabla \beta|^2 + |\gamma|^2 \leq C_0(|\alpha|^2 + |\beta|^2 + |\mathbf{b}|^2). \]

(4.19)

\[ |\xi|^2 \leq C_0 (|\partial_t^2 \mathbf{u}^{(1)}(\mathbf{x}, 0)|^2 + |\partial_t^2 \mathbf{u}^{(2)}(\mathbf{x}, 0)|^2). \]

(4.20)

Taking the derivative with respect to the variable \( x_k \) on both sides of (4.18), shows that
\[ \mathbf{D}_0^{(j)} \partial_k \xi = - (\partial_k \rho_0) \partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0) - \rho_0 \partial_k \partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0) - (\partial_k \mathbf{D}_0^{(j)}) \xi, \]

and hence
\[ |\nabla \xi|^2 \leq C_0 \sum_{j=1}^2 \left( (\partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0))^2 + |\nabla \partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0)|^2 \right). \]

(4.21)

Therefore
\[ \int_{\Omega} e^{2\pi \rho_0 (|\xi|^2 + |\nabla \xi|^2)} \leq C_0 \int_{\Omega_0} e^{2\pi \rho_0 \left( \sum_{j=1}^2 \left( (\partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0))^2 + |\nabla \partial_t^2 \mathbf{u}^{(j)}(\mathbf{x}, 0)|^2 \right) \right)} \]

(4.22)

In addition, taking the derivative with respect to the variable \( x_k \) on both sides of (4.17), we obtain
\[ \mathbf{M}(\mathbf{x}) \begin{pmatrix} \nabla \partial_k \alpha \\ \partial_k \gamma \\ \nabla \partial_k \beta \end{pmatrix} = \partial_k \mathbf{N}(\mathbf{x}) \begin{pmatrix} \alpha \\ \beta \end{pmatrix} + \mathbf{N}(\mathbf{x}) \begin{pmatrix} \partial_k \alpha \\ \partial_k \beta \end{pmatrix} + \partial_k \mathbf{b}(\mathbf{x}) - \partial_k \mathbf{M}(\mathbf{x}) \begin{pmatrix} \nabla \alpha \\ \gamma \\ \nabla \beta \end{pmatrix}, \]

and hence
\[ |\nabla\nabla\alpha|^2 + |\nabla\nabla\beta|^2 + |\nabla\gamma|^2 \leq C_0(|\alpha|^2 + |\beta|^2 + |b|^2 + |\nabla b|^2). \] (4.23)

Therefore
\[ \int_{\Omega} e^{2\tau v_0}(|\nabla\nabla\alpha|^2 + |\nabla\nabla\beta|^2 + |\nabla\gamma|^2) \]
\[ \leq C_0 \int_{\Omega} e^{2\tau v_0}(|\alpha|^2 + |\beta|^2) + C_0 \int_{Q_0} e^{2\tau v_0}(|b|^2 + |\nabla b|^2), \]
\[ \leq C_0 \int_{\Omega} e^{2\tau v_0}(|\alpha|^2 + |\beta|^2) + C_0 \int_{Q_0} e^{2\tau v_0}(|b|^2 + |\nabla b|^2). \] (4.24)

because \( \alpha, \beta \) are supported in \( \Omega_0 \). We recall one lemma from [9].

**Lemma 4.1.** There exists constant \( \tau_0 > 0 \) and \( C_0 > 0 \) such that, for all \( \tau > \tau_0 \) and \( v \in H_0^1(\Omega) \),
\[ \tau \int_{\Omega} e^{2\tau v_0} |v|^2 \leq C_0 \int_{\Omega} e^{2\tau v_0} (|\text{curl} v|^2 + |\text{div} v|^2). \]

Applying lemma 4.1 with \( v = \nabla\alpha \), we have
\[ \tau \int_{\Omega} e^{2\tau v_0} |\nabla\alpha|^2 \leq C_0 \int_{\Omega} e^{2\tau v_0} |\Delta\alpha|^2 \leq C_0 \int_{\Omega} e^{2\tau v_0} |\nabla\nabla\alpha|^2, \]
and hence
\[ \tau \int_{\Omega} e^{2\tau v_0} (|\nabla\alpha|^2 + |\nabla\beta|^2) \leq C_0 \int_{\Omega} e^{2\tau v_0} (|\nabla\nabla\alpha|^2 + |\nabla\nabla\beta|^2). \]

Combining with (4.19) and (4.24), we finally obtain the bound
\[ \int_{\Omega} e^{2\tau v_0} \tilde{A} \leq C_0 \int_{Q_0} e^{2\tau v_0} (|b|^2 + |\nabla b|^2) \] (4.25)
for \( \tau \) large enough.

### 4.3. End of the proof of theorem 4.1

We recall the following lemma from [3].

**Lemma 4.2.** There exist constants \( \tau_0 > 0 \) and \( C_0 > 0 \) such that, for all \( \tau > \tau_0 \) and \( v \in C^1(Q_0(\delta)) \),
\[ \int_{Q_0} |v(x,0)|^2 \leq C_0 \tau \int_{Q_0(\delta)} |v(x,t)|^2 + C_0 \tau^{-1} \int_{Q_0(\delta)} |\partial_t v(x,t)|^2. \]

We recall that \( \Omega_0 = \Omega \setminus \varnothing \) and \( Q_0(\delta) = \Omega_0 \times (-T + \delta, T - \delta) \).

By taking \( v = e^{\tau v_0} \partial_t D^{(j)}(x,0) \) in the above estimate and invoking (4.11) to control the derivatives of \( D^{(j)}(x,0) \), we see that
\[ \int_{Q_0} e^{2\tau v_0} |\partial_t D^{(j)}(x,0)|^2 \leq C_0 \tau \int_{Q_0(\delta)} e^{2\tau v_0} |\partial_t D^{(j)}|^2 + C_0 \tau^{-1} \int_{Q_0(\delta)} e^{2\tau v_0} |\partial_t^2 D^{(j)}|^2 \]
\[ \leq C_0 \tau^{-1} \mathcal{E}^{(j)}. \]
from (4.12), where
\[
\varepsilon^{(j)} = \int_0 e^{2\tau\varphi} \Lambda + e^{2\tau\Phi} \mathcal{D}^{(j)} + e^{2\tau(1-2\epsilon)} .
\]

We proceed similarly with the higher-order derivatives of \(D^{(j)}(x, 0)\) and with the other fields, to obtain
\[
\int_{\Omega_0} e^{2\tau\varphi} |\partial_k \partial_0 D^{(j)}(x, 0)|^2 \leq C_0 \tau \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial_0 D^{(j)}|^2 + C_0 \tau^{-1} \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial^2 D^{(j)}|^2 \\
\leq C_0 \varepsilon^{(j)} ,
\]
\[
\int_{\Omega_0} e^{2\tau\varphi} |\partial_k \partial_0 B^{(j)}(x, 0)|^2 \leq C_0 \tau \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial_0 B^{(j)}|^2 + C_0 \tau^{-1} \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial^2 B^{(j)}|^2 \\
\leq C_0 \varepsilon^{(j)} ,
\]
\[
\int_{\Omega_0} e^{2\tau\varphi} |\partial_k \partial_0 \tau \phi^{(j)}(x, 0)|^2 \leq C_0 \tau \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial_0 \tau \phi^{(j)}|^2 + C_0 \tau^{-1} \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial^2 \tau \phi^{(j)}|^2 \\
\leq C_0 \varepsilon^{(j)} ,
\]
\[
\int_{\Omega_0} e^{2\tau\varphi} |\partial_k \partial^2 \tau \phi^{(j)}(x, 0)|^2 \leq C_0 \tau \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial^2 \tau \phi^{(j)}|^2 + C_0 \tau^{-1} \int_{Q_0(\delta)} e^{2\tau\varphi} |\partial_k \partial^3 \tau \phi^{(j)}|^2 \\
\leq C_0 \varepsilon^{(j)} .
\]

It follows that
\[
\int_{\Omega_0} e^{2\tau\varphi} \left( |b|^2 + |\nabla b|^2 \right) \leq C_0 \left( \varepsilon^{(1)} + \varepsilon^{(2)} \right),
\]
\[
\int_{\Omega_0} e^{2\tau\varphi} \left( \sum_{j=1}^2 \left( |\partial^2 \tau \phi^{(j)}(x, 0)|^2 + |\nabla \partial^2 \tau \phi^{(j)}(x, 0)|^2 \right) \right) \leq C_0 \left( \varepsilon^{(1)} + \varepsilon^{(2)} \right).
\]

From (4.22) and (4.25), we infer that
\[
\int_{\Omega} e^{2\tau\varphi} \Lambda - C_0 \int_Q e^{2\tau\varphi} \Lambda \leq C_0 e^{2\tau \Phi} (\mathcal{D}^{(1)} + \mathcal{D}^{(2)}) + C_0 e^{2\tau(1-2\epsilon)} .
\]

Since \(\varphi - \varphi_0 < 0\) for \(|t| > 0\), by choosing \(\tau_0\) large enough we can make \(\int_{-\tau}^T e^{2\tau(\varphi - \varphi_0)}\) so small that for all \(\tau > \tau_0\),
\[
\int_Q e^{2\tau\varphi} \Lambda = \int_{\Omega} e^{2\tau\varphi} \Lambda \int_{-\tau}^T e^{2\tau(\varphi - \varphi_0)} \ll \int_{\Omega} e^{2\tau\varphi} \Lambda .
\]

Combining this estimate with (4.28) and using the fact that \(\varphi_0 \geq 1 - \epsilon\), it follows that
\[
\int_{\Omega} \Lambda \leq e^{-2\tau(1-\epsilon)} \int_{\Omega} e^{2\tau\varphi_0} \Lambda \leq C_0 e^{2\tau \Phi} (\mathcal{D}^{(1)} + \mathcal{D}^{(2)}) + C_0 e^{-2\tau \epsilon}
\]
for all \(\tau > \tau_0\). Taking
\[ \tau - \tau_0 = -\frac{\ln \left( O^{(1)} + O^{(2)} \right)}{2(\Phi + \epsilon)} \]

we finally obtain

\[ C_0 e^{2\tau_0 \Phi} (O^{(1)} + O^{(2)}) + C_0 e^{-2\tau_0 \epsilon} \leq C_0 e^{2\tau_0 \Phi} e^{2(\tau - \tau_0)\Phi} (O^{(1)} + O^{(2)}) + C_0 e^{-2\tau_0 \epsilon} e^{-2(\tau - \tau_0)\epsilon} = C_0 (O^{(1)} + O^{(2)}) e^{\tau \Phi}, \]

which completes the proof.

5. Conclusion

We presented a complete electroseismic model that describes the coupling phenomenon of the electromagnetic waves and seismic waves in fluid immersed porous rock. Under some assumptions on the physical parameters, we derived a Hölder stability estimate to the inverse problem of recovery of the electric parameters and the coupling coefficient from interior measurements near the boundary. How to relax the constraints on the physical parameters will be the objective of future works.
