SIGMA THEORY FOR BREDON MODULES

D. H. KOCHLOUKOV AND C. MARTÍNEZ-PÉREZ

ABSTRACT. We develop new invariants $\Sigma^m(G, A)$ similar to the Bieri-Strebel-Neumann-Renz invariants $\Sigma^m(G, A)$ but in the category of Bredon modules $A$ (with respect to the class of the finite subgroups of $G$). We prove that for virtually soluble groups of type $FP_\infty$ and finite extension of the Thompson group $F$ we have $\Sigma^\infty(G, \mathbb{Z}) = \Sigma^\infty(G, \mathbb{Z})$.

1. INTRODUCTION

Bredon cohomology with respect to the family of finite subgroups can be intuitively understood as the cohomology theory obtained by considering proper (i.e., with finite stabilizers) actions instead of free actions of groups. In this paper we introduce $\Sigma$-theory for the class of Bredon modules similar to the classical Bieri-Strebel-Neumann-Renz theory developed since 1980’s. In the classical case modules $A$ over the group algebra $\mathbb{Z}G$ are considered and by definition a class $[\chi]$ of a non-trivial character $\chi : G \to \mathbb{R}$ is in $\Sigma^m(G, A)$ if $A$ is of type $FP_m$ over $\mathbb{Z}G$, where $G_\chi$ is the monoid $\{g \in G | \chi(g) \geq 0\}$. An early version of $\Sigma^1(G, \mathbb{Z})$ was used as an important tool in the classification of all finitely presented metabelian groups by Bieri and Strebel [7]. The importance of the invariant $\Sigma^m(G, \mathbb{Z})$ lies in the fact that it classifies which subgroups of $G$ above the commutator are of type $FP_m$ [5]. One of our main results, Theorem D below, is that the analogous statement holds for Bredon cohomology for the newly defined Bredon $\Sigma$-invariants.

Finiteness cohomological conditions in Bredon cohomology play the same role when studying proper classifying spaces that ordinary finiteness cohomological properties for ordinary classifying spaces. Recall that for a group $G$ a $G$-CW complex $X$ is a model for $\mathbb{E}G$, the proper classifying space, if $X^H$ is contractible whenever $H \leq G$ is finite and empty otherwise.

Then, if there is a model for $\mathbb{E}G$ with cocompact 2-skeleton and $G$ is of type Bredon $FP_n$, also denoted $FP_n$ (see Section 2 for a definition), one can show that there exists a model for $\mathbb{E}G$ with finite $n$-skeleton. This follows using the $n$-dimensional version of [16] Theorem 4.2, which in turn can be proven truncating at dimension $n$ the inductive procedure used there. In this paper we create a Bredon version of the homological $\Sigma$-invariants and hope that in future the question of homotopic Bredon $\Sigma$-invariants can be addressed.

We first develop general Bredon theory for modules over cancelation monoids and later concentrate on monoids $G_\chi$, where $G$ is a group and $\chi$ a non-zero real character of $G$. The main obstacle to develop a general $\Sigma$-theory is that the sets $[M/K, M/H]$ (see Section 2 for notation), where $K$ and $H$ are finite subgroups of the cancelation monoid $M$, are not always finitely generated over the Weyl monoid.

Date: February 5, 2013.

2000 Mathematics Subject Classification. 2005.
\(W_MK\) and to avoid this problem we consider special monoids \(M\), namely cancelation monoids that conjugate finite subgroups. For these monoids we describe the Bredon type \(FP_n\) in the following result (see Corollary 6.13).

**Theorem A.** A cancelation monoid \(M\) which conjugates finite subgroups is of type \(FP_n\) if and only if there are finitely many finite subgroups \(H_1, \ldots, H_s\) such that for each finite subgroup \(K\) of \(M\) there is an element \(m \in M\) such that \(km \subseteq mH\) for some \(i = 1, \ldots, s\) and \(W_MK\) is of type \(FP_n\).

In section 6 we define the new invariant \(\Sigma^m(G, A)\) for an \(\mathcal{O} \neq G\)-module \(A\) and study it in detail for the trivial module \(\mathbb{Z}\). The following result (see Theorem 6.6) classifies the elements of the new invariant in terms of the classical \(\Sigma\)-invariant.

**Theorem B.** Suppose that \(G\) is a finitely generated group and has finitely many conjugacy classes of finite subgroups. Then \(\{|\chi| \in \Sigma^m(G, \mathbb{Z})\}\) if and only if there is a subgroup \(\widetilde{G}\) of finite index in \(G\) that contains the commutator subgroup \(G'\), and such that for every finite subgroup \(K\) of \(G\) we have \(K \leq \widetilde{G}\) and

1. \(N_G(K)(\ker(\chi) \cap \widetilde{G}) = \widetilde{G}\)
2. \(\chi(N_G(K)) \neq 0\) and \(\{\chi|_{N_G(K)}\} \in \Sigma^m(N_G(K), \mathbb{Z})\).

Furthermore condition 2 can be substituted for condition 2b. \(\chi(C_G(K)) \neq 0\) and \(\{\chi|_{C_G(K)}\} \in \Sigma^m(C_G(K), \mathbb{Z})\).

By one of the main results in \([5]\) the classical \(\Sigma\) invariant is always an open subset of the character sphere \(S(G)\). In the Bredon case the situation is slightly different and we have the following result (see Theorem 6.11).

**Theorem C.** Suppose that \(\Sigma^m(G, \mathbb{Z}) \neq \emptyset\). Then \(\Sigma^m(G, \mathbb{Z})\) is open in \(S(G)\) if and only if \(N_G(K)G'\) has finite index in \(G\) for every finite subgroup \(K\).

In [5, Thm. B] it was shown that for a group \(G\) of homological type \(FP_m\) and a subgroup \(H\) of \(G\) that contains the commutator of \(G\) we have that \(H\) is of type \(FP_m\) if and only if \(S(G, H) = \{|\chi| \mid \chi(H) = 0\} \subseteq \Sigma^m(G, \mathbb{Z})\). We establish the following Bredon version of [5, Thm. B] (see Theorem 6.8).

**Theorem D.** Let \(H\) be a subgroup of \(G\) that contains the commutator and \(G/H\) is torsion-free and non-trivial. Then \(\mathbb{Z}\) is Bredon \(FP_m\) as \(\mathcal{O} \neq H\)-module if and only if \(S(G, H) \subseteq \Sigma^m(G, \mathbb{Z})\).

Finally in the last two sections of the paper we consider the case of virtually soluble groups of type \(FP_n\) or finite extension of the R. Thompson group \(F\). In both cases the groups are known to be of type Bredon \(FP_{\infty}\) [11], [17]. The proofs of both cases of Theorem E (see Theorem 8.8 and Theorem 7.5) use Theorem B and the techniques developed to prove that \(G\) is of type Bredon \(FP_{\infty}\) in [11], [17].

**Theorem E.** If \(G\) is virtually soluble of type \(FP_{\infty}\) or is a finite extension of the R. Thompson group \(F\) then \(\Sigma^m(G, \mathbb{Z}) = \Sigma^m(G, \mathbb{Z})\).

Acknowledgements : We thank Brita Nucinkis for the fruitful talks on the new Bredon Sigma invariants which finally led to this article. The second author thanks the department of mathematics at UNICAMP, Brazil for the hospitality during a visit of a week in September, 2011 when some parts of the current paper were developed and thanks FAPESP, Brazil for the travel grant for a visit to Brazil including the participation at a workshop on group theory in Ubatuba, September 2011. She was also supported by Gobierno de Aragon, European Regional Development.
2. SOME BREEDON COHOMOLOGY FOR MONOIDS

Let $M$ be a monoid. We say that $M$ is of type $FP_n$ if the trivial left module $\mathbb{Z}$ is of type $FP_n$ over the monoid ring $\mathbb{Z}M$. If not otherwise stated the modules considered in the paper are left ones. Observe that for a monoid $M$ defining type $FP_n$ using the right trivial $\mathbb{Z}M$-module $\mathbb{Z}$ might yield different result. Even for the monoid $M = G_\chi = \{g \in G \mid \chi(g) \geq 0\}$ that comes from a non-zero real character $\chi : G \to \mathbb{R}$, where $G$ is a finitely generated group, we might have that the trivial left $\mathbb{Z}M$-module $\mathbb{Z}$ is $FP_n$, but the trivial right $\mathbb{Z}M$-module $\mathbb{Z}$ is not $FP_n$. For example if we consider the Bieri-Strebel-Neumann-Renz invariant $\Sigma^n(G, \mathbb{Z})$ defined for left $\mathbb{Z}G$-modules $\mathbb{Z}$ it suffices that $[\chi] \in \Sigma^n(G, \mathbb{Z})$ but $[-\chi] \notin \Sigma^n(G, \mathbb{Z})$. This is a consequence of the fact that if $\mathbb{Z}$ were $FP_m$ as a right $M$-module, then via $g \mapsto g^{-1}$ one could show that $\mathbb{Z}$ would be $FP_m$ as a left $G - \chi$-module, contradicting that $[-\chi] \notin \Sigma^n(G, \mathbb{Z})$. As shown in [10] even the notion of finite cohomological dimension for a monoid depends on the choice of left or right modules.

Definition 2.1. We say that a monoid $M$ is a left (resp. right) cancelation monoid if for any $m, m_1, m_2 \in M$ such that $mm_1 = mm_2$ (resp. such that $m_1m = m_2m$) we have $m_1 = m_2$. And we say that $M$ is a cancelation monoid if it is both left and right cancelation monoid.

From now on until the end of this section we assume that $M$ is a cancelation monoid unless otherwise stated. We say that a $(left)$ $M$-set $\Delta$ is transitive if it is generated by a single $\omega \in \Delta$, i.e., if $\Delta = M\omega$. We say that an $M$-set $\Delta$ is restricted if it is a disjoint union of transitive $M$-sets, i.e.,

$$\Delta = \bigcup_{\lambda \in \Lambda} \Delta_\lambda$$

where $\Lambda$ is a set and each $\Delta_\lambda$ is transitive.

If $\Lambda$ is finite, we say that $\Delta$ is $M$-finite. And if the stabilizer in $M$ of any generator of each $\Delta_\lambda$ is a finite submonoid, then we say that $\Delta$ is proper. Note that since $M$ is a cancelation monoid any finite submonoid is a subgroup. For example, for the monoid $M = \{x^n \mid n \geq 0\}$ the $M$-set $\{x^n \mid n \in \mathbb{Z}\}$ with left $M$-action given by multiplication is not restricted. Neither is the finitely generated $M$-set $X := M \cup \mathbb{M} / \sim$, where $\sim$ consists of identifying the two copies of $x^i$ whenever $i \geq i_0$ for a fixed $i_0 > 0$.

We define the orbit category $\mathcal{O}_M$ to be the category with objects the transitive proper $M$-sets. We denote the objects of $\mathcal{O}_M$ by $M/K$, where $K$ is a finite subgroup of $M$. Here $M/K = \{mK \mid m \in M\}$. Morphisms in $\mathcal{O}_M$ are $M$-maps $\phi : M/K \to M/H$ and are uniquely determined by $\phi(K) = M/H$. For this to be well defined we need $Km \subseteq mH$. The set of morphisms $\text{mor}(M/K, M/H)$ is denoted $[M/K, M/H] = \{mH \mid Km \subseteq mH\}$.

In the particular case when $K = H$ we set $W_M := [M/K, M/K]$.

Note that since $M$ is a cancelation monoid the sets $mK$ and $Km$ have the same cardinality as $K$, hence $W_M = \{mK \mid mK = Km\}$ and $W_M$ is a cancelation monoid which we call the Weyl monoid for $K$ in analogy with Weyl groups.
As in the group case, we may define a Bredon module, or $\mathcal{O}_\mathcal{G}M$-module $V(-)$, as a contravariant functor from $\mathcal{O}_\mathcal{G}M$ to the category of abelian groups. The Bredon modules form an abelian category so we have (co)products and (co)limits, exact sequences etc are defined analogously.

By definition a free Bredon module is one of the form $\mathbb{Z}[-,\Delta]$, where $\Delta$ is a restricted proper $M$-set. We say that a morphism in the category of Bredon modules $V(-) \to W(-)$ is an epimorphism if for every $M/K \in \mathcal{O}_\mathcal{G}M$ we have that the map $V(M/K) \to W(M/K)$ is surjective. It is easy to see that every Bredon module is an epimorphic image of a free Bredon module. Following the same procedure as in the group case, see [20], one can show that the category of $\mathcal{O}_\mathcal{G}M$-modules has enough projectives and then define cohomology and homology.

Observe also that for any $\mathcal{O}_\mathcal{G}M$-module $V$ and any finite subgroup $K \leq M$, the functor $V(-)$ yields a structure of $W_MK$-module in $V(M/K)$. In particular case when $V(-) = \mathbb{Z}[-,M/H]$ this action is given by $xKmH = xmH$ for $xK \in W_MK$, $m \in M$ (for example, if $M$ has no finite subgroups, then a $\mathcal{O}_\mathcal{G}M$-module is just an $M$-module). But note that the condition that $\Delta$ is restricted in the definition of a free Bredon module is necessary, for example consider again the monoid $M = \{x^n \mid n \geq 0\}$ and $\Delta = \{x^n \mid n \in \mathbb{Z}\}$. Then the $\mathcal{O}_\mathcal{G}M$-module $\mathbb{Z}[-,\Delta]$ is just the $M$-module $\mathbb{Z}\Delta$ which can not be projective (an easy way to see it is to observe that for any $a \in \mathbb{Z}\Delta$, there is some $b \in \mathbb{Z}\Delta$ with $xb = a$, something that can not happen in any submodule of a free $M$-module).

By definition an $\mathcal{O}_\mathcal{G}M$-set $\Sigma$ is a collection of sets $\Sigma_K$, one for each finite subgroup $K \leq M$. We say that $\Sigma$ is $\mathcal{O}_\mathcal{G}M$-finite if $\Sigma_K$ is finite for each $K$ and empty for all but finitely many subgroups $K$. As for groups ([15, Section 9]), an $\mathcal{O}_\mathcal{G}M$-module $U$ is finitely generated if there is an $\mathcal{O}_\mathcal{G}M$-finite $\mathcal{O}_\mathcal{G}M$-set $\Sigma$ such that for each finite subgroup $K$, $\Sigma_K \subseteq U(M/K)$ and there is no proper submodule $V(-)$ of $U(-)$ with $\Sigma_K \subseteq V(M/K)$ for any finite subgroup $K$. If we put $\Delta_K = M/K \times \Sigma_K$ seen as $M$-set with trivial action on the right hand factor and $\Delta := \bigcup \{\Delta_K \mid K \leq M$ finite subgroup $\}$, then there is a surjection $\rho : \mathbb{Z}[-,\Delta] \to U(-)$.

And conversely, if there is such a surjection $\rho$ for some restricted $M$-finite proper $M$-set $\Delta$, then $U(-)$ is finitely generated.

The finiteness conditions $\text{FP}_n$, $\text{FP}_\infty$, and $\text{FP}$ for $\mathcal{O}_\mathcal{G}M$-modules are defined as usual and we say a cancelation monoid $M$ satisfies any of the above finiteness conditions if the trivial $\mathcal{O}_\mathcal{G}M$-module $\mathbb{Z}$ does, where $\mathbb{Z}$ is the $\mathcal{O}_\mathcal{G}M$-module with $\mathbb{Z}(M/K) = \mathbb{Z}$ for any $K$ finite and with all the maps equal to the identity.

In particular if $M = G$ is a group this defines the finiteness conditions $\text{FP}_n$, $\text{FP}_\infty$, and $\text{FP}$ for $\mathcal{O}_\mathcal{G}G$-modules, also called Bredon finiteness conditions. Our main objective in the rest of this section is to generalize to monoids (under reasonable extra hypotheses) the following well known characterization

**Lemma 2.2.** ([16, Lemma 3.2]) A group $G$ is of type $\text{FP}_n$ if and only if it has finitely many conjugacy classes of finite subgroups and moreover for each finite subgroup $K$, the Weyl group $W_GK = N_G(K)/K$ is of type $\text{FP}_n$.

We begin with the case $n = 0$.

**Lemma 2.3.** A cancelation monoid $M$ is of type $\text{FP}_n$ if and only if there are finitely many finite subgroups $H_1,\ldots,H_n$ of $M$ such that for each finite subgroup $K$ of $M$ there is an element $m \in M$ such that $Km \subseteq mH_i$ for some $i = 1,\ldots,n$. 
Proof. Note that $M$ is of type $\text{FP}_0$ if and only if there is a restricted $M$-finite proper $M$-set $\Delta = \bigcup_{i=1}^{n} M/H_i \times \Delta_i$ (i.e. every $\Delta_i$ is finite) such that $\mathbb{Z}[-,\Delta]$ surjects onto $\mathbb{Z}[-]$). This means that for any finite subgroup $K$, $\mathbb{Z}[M/K,\Delta] \neq 0$ thus there is an $m \in M$ such that $K m \subseteq m H_i$ for some $i$. □

**Definition 2.4.** Let $M$ be a monoid. We say that $M$ conjugates finite subgroups if for any $H_1, H_2 \leq M$ finite such that $H_1 g = g H_2$ for some $g \in M$, there exists a $h \in M$ invertible with $H_1^h = H_2$, where $H_1^h = h^{-1} H_1 h$. We say that $M$ has finitely many conjugacy classes of finite subgroups if there is a finite family of finite subgroups $\{K_1, \ldots, K_t\}$ such that for any finite subgroup $L \leq M$ there is some $i$ and some invertible $t \in M$ such that $L = t^{-1} K_t$.

**Proposition 2.5.** Let $M$ be a cancelation monoid of type $\text{FP}_0$ that satisfies the following two conditions:

i. For any finite subgroups $K, L$ of $M$ the $W_M K$-module $\mathbb{Z}[M/K, M/L]$ is of type $\text{FP}_m$.

ii. $M$ has finitely many conjugacy classes of finite subgroups.

Then a $\mathcal{O}_M$-$M$-module $V$ is of type $\text{FP}_n$ if and only if for each finite subgroup $K$ of $M$, $V(M/K)$ is a module of type $\text{FP}_n$ over $W_M K$.

**Proof.** If $V$ is of type $\text{FP}_n$, then there is a projective resolution $P_i(-) \rightarrow V(-)$ such that $P_i(-)$ is finitely generated for all $i \leq n$. We may assume that for $i \leq n$ the $P_i(-)$ are finitely generated free, hence of the form $\mathbb{Z}[-,\Delta_i]$ with $\Delta_i$ a restricted $M$-finite $M$-set. Thus $\mathbb{Z}[-,\Delta_i] = \bigoplus_{j=1}^{m_i} \mathbb{Z}[-, M/L_j]$ for some finite subgroups $L_j$ (here we allow repetitions). Note that for any finite subgroup $K$, $P_i(M/K) \rightarrow V(M/K)$ is an exact sequence of modules. Since each $P_i(M/K)$ is of type $\text{FP}_m$ as $W_M K$-module for $i \leq n$ this yields the result by dimension shifting (Proposition 1.4).

Assume now that $V$ is an $\mathcal{O}_M$-$M$-module such that each $V(M/K)$ is finitely generated as $W_M K$-module. Choose a set $\Omega$ of representatives of each conjugacy class of finite subgroups, so $\Omega$ is finite. For each $K \in \Omega$, let $\Sigma_K$ be a finite generating system of $V(M/K)$ as $W_M K$-module. Then the $\mathcal{O}_M$-$M$-set $\Sigma$ which corresponds to $\Sigma_K$ whenever $K \in \Omega$ and is empty otherwise is $\mathcal{O}_M$-$M$-finite and generates $V$ as $\mathcal{O}_M$-$M$-module. As a consequence, there is a finitely generated free $\mathcal{O}_M$-$M$-module $P$ and an epimorphism $P \rightarrow V$. This proves the case $n = 0$ of the “if” part. For the general case, argue by induction, exactly as in [13] Lemma 3.1. Explicitly, assume that the result holds for $n - 1$ and consider the $n$-th kernel $U_n$ of a projective resolution of $V$ as $\mathcal{O}_M$-$M$-module formed, up to degree $n - 1$, by finitely generated free Bredon modules. Then the fact that evaluating a finitely generated free module at each $M/K$ yields a $W_M K$-module of type $\text{FP}_m$ and the hypothesis that $V(M/K)$ is $\text{FP}_n$ imply that each $U_n(M/K)$ is finitely generated and the preceding paragraph yields that $U_n$ is finitely generated, hence $V$ is also $\text{FP}_n$. □

**Lemma 2.6.** Let $M$ be a cancelation monoid and $\Delta$ be a restricted $M$-finite proper $M$-set. Then the permutation $M$-module $\mathbb{Z} \Delta$ is of type $\text{FP}_m$.

**Proof.** Note that it suffices to consider the case when $\Delta$ is $M$-transitive i.e. we may assume that $\Delta = M/K$ for some finite subgroup $K$ of $M$. Then the assertion is obvious as $\mathbb{Z}$ is of type $\text{FP}_m$ as $ZK$-module and the induction functor from $K$-modules to $M$-modules is exact and takes finitely generated projectives to finitely generated projectives. □
Lemma 2.7. Let $H, K \leq M$ be finite subgroups of the cancelation monoid $M$. There are subgroups $K_1, \ldots, K_r \leq H$ such that there is a decomposition as $W_M K$-set
\[
[M/K, M/H] = \bigcup_{i=1}^r \Omega_i \quad \text{where} \quad \Omega_i := \{mH \mid Km = mK_i\}.
\]
Furthermore any two sets $\Omega_i$ and $\Omega_j$ are either disjoint or equal. In particular if we take a decomposition where $s$ is minimal, the union in (1) is disjoint.

Proof. Fix $mH \in [M/K, M/H]$ and let
\[
\overline{K} := \{h \in H \mid mh \in Km\}.
\]
Given $h_1, h_2 \in \overline{K}$, there are some $k_1, k_2 \in K$ such that $mh_1 = k_1m$ and $mh_2 = k_2m$.
Then $m(h_1h_2) = k_1k_2m$ thus $\overline{K}$ is a subgroup of $H$. Obviously, $m\overline{K} \subseteq Km$ and conversely, as $Km \subseteq m\overline{K}$ one gets $Km \subseteq m\overline{K}$, hence $Km = m\overline{K}$. As for $xK \in W_M K$, $xm\overline{K} = xKm = Kxm$, the monoid $W_M K$ acts on $\{mH \mid Km = mK_i\}$. Since $H$ is finite, there are finitely many subgroups $\overline{K}$ that can be obtained in this form so the first assertion follows.

Suppose \(\{mH \mid Km = mK_i\} \cap \{mH \mid Km = mK_j\} \neq \emptyset\) for some $i \neq j$, so there are $a_1, a_2 \in M$ such that $a_1H = a_2H$, $K_{a_1} = K_{a_2}$ and $K_{a_1} = a_2K_j$. Then $a_2 = a_2h$ for some $h \in H$ and hence $K_{a_2h} = K_{a_1} = a_1K_i = a_2hK_i$, so
\[
a_2K_j = K_{a_2}K_i^{-1} = a_2K_i^{-1}.
\]
Since $M$ is a cancelation monoid $K_j = K_i^{a_2}$, so $\{mH \mid Km = mK_j\} = \{mH \mid Kmh = mhK_i\} = \{m_0H \mid K_{m_0} = m_0K_i\}$. \hfill \Box

Definition 2.8. We say that a monoid $M$ has the left linear property if for every $m_1, m_2 \in M$ at least one of the linear equations $xm_1 = m_2$ and $xm_2 = m_1$ has a solution in $M$.

Lemma 2.9. Assume that $M$ is a cancelation monoid with the left linear property. Let $\Omega_i$ be one of the disjoint sets from Lemma 2.7 and assume that $\Omega_i$ is finitely generated over $W_M K$. Then $\Omega_i$ is $W_M K$-transitive.

Proof. Let $m_1H, m_2H \in \Omega_i$. Since $M$ has the left linear property there is $f \in M$ such that $fm_1 = m_2$ or $fm_2 = m_1$. Assume $m_1 = fm_2$. Then $Kfm_2 = Km_1 = m_1K_i = fm_2K_i = fKm_2$. Since $M$ is a cancelation monoid we deduce that $Kf = fK$, so $fK \in W_M K$. Hence $m_1H \in W_M K(m_2H)$.

Finally if $m_1H, \ldots, m_kH$ is a generating set of $\Omega_i$ over $W_M K$ then the previous paragraph implies that $\Omega_i$ is transitive and reordering we may assume $\Omega_i = W_M K(m_1H)$. \hfill \Box

Lemma 2.10. Assume that $M$ is a cancelation monoid and that for some fixed finite subgroups $K, H$ of $M$ each of the $W_M K$-sets $\Omega_i$ of Lemma 2.7 is $W_M K$-transitive. Then the $W_M K$-module $\mathbb{Z}[M/K, M/H]$ is of type $\text{FP}_n$.

Proof. The hypothesis implies that the $W_M K$-set $[M/K, M/H]$ is $W_M K$-finite and restricted. By Lemma 2.6 we only have to check that it is also proper.

Set $L_i = \{xK \in W_M K \mid xmH = mH\}$, where $\Omega_i = W_M K(m_iH)$. The fact that $M$ is a cancelation monoid implies that for $f_1, f_2 \in m_iH$ the linear equation $xf_1 = f_2$ has at most one solution in $M$, thus $L_i$ is finite. Since it has the left cancelation property, it is a subgroup. \hfill \Box
Lemma 2.11. Assume that $M$ is a type $\text{FP}_0$ cancelation monoid that conjugates finite subgroups. Then $M$ has finitely many conjugacy classes of finite subgroups.

Proof. By Lemma 2.10, there are finitely many finite subgroups $H_1, \ldots, H_s$ such that for each finite subgroup $K$ of $M$ we have $Km \subseteq mH_i$ for some $m \in M$ and some $i = 1, \ldots, s$. Then following the first part of the proof of Lemma 2.10 we see that $Km = mK_i$, where $K$ is a finite subgroup of $H_i$. Then since $M$ conjugates finite subgroups there is an invertible $t \in M$ such that $K' = \bar{K} \leq H_i$. □

Corollary 2.12. Let $M$ be a type $\text{FP}_0$ cancelation monoid that conjugates finite subgroups. Then a $G \times M$-module $V$ is of type $\text{FP}_n$ if and only if for each finite subgroup $K$ of $M$, $V(M/K)$ is a module of type $\text{FP}_n$ over $W_M K$.

Proof. By Proposition 2.5, Lemma 2.10, and Lemma 2.11, it suffices to show that for any finite subgroup $K, H$ of $M$ each of the the $W_M K$-sets $\Omega_i$ of Lemma 2.7 is transitive. To see it, note that since $M$ conjugates finite subgroups for each $K_i$ with $Km = mK_i$, we must have $K_i = K^m$ for some $m_i \in M$ invertible. Then $\{mH \mid Km = mK_i\} = W_k M(m_i H)$. □

Corollary 2.13. A cancelation monoid $M$ which conjugates finite subgroups is of type $\text{FP}_n$ if and only if for each finite subgroup $K$ of $M$ there is an element $m \in M$ such that $Km \subseteq mH_i$ for any finite subgroup $H_i$ of $M$. Then $W_M K$ is of type $\text{FP}_n$.

Proof. It follows from Lemma 2.3 and Corollary 2.12 applied for $V = \mathbb{Z}$. □

3. The case of monoids obtained from characters

Let $G$ be a group and $\chi : G \rightarrow \mathbb{R}$ be a non-zero homomorphism. Consider the monoid

$$G_\chi = \{g \in G \mid \chi(g) \geq 0\}.$$

Note that every finite subgroup of $G$ is contained in $G_\chi$. Recall that

(2) if $G_\chi$ is of type $\text{FP}_m$ then $G$ is of type $\text{FP}_m$.

From now on fix the monoid $M = G_\chi$. Note that $W_M K = (W_G K)_\chi = N_G(K)_\chi / K$.

Lemma 3.1. Let $\chi : G \rightarrow \mathbb{R}$ be a non-zero character. Then $G_\chi$ is a cancelation monoid with the left linear property.

Proof. Let $f_1, f_2 \in G_\chi$. Then either $f_1^{-1} f_2 \in G_\chi$ or $f_2^{-1} f_1 \in G_\chi$, so $G_\chi$ has the left linear property. Since $G_\chi$ is embedable in a group it is a cancelation monoid. □

Remark 3.2. As a consequence of this and of Lemma 2.9 we get that if $\chi : G \rightarrow \mathbb{R}$ is a non-zero character and $H, K$ are finite subgroups of $G$, then $[G_\chi / K, G_\chi / H]$ is finitely generated as $W_{G_\chi} K$-set if and only if each of the sets $\Omega_i$ in Lemma 2.7 is $W_{G_\chi} K$-transitive.

Lemma 3.3. Let $\chi : G \rightarrow \mathbb{R}$ be a non-zero character. Then $G_\chi$ conjugates finite subgroups if and only if $G_\chi \subseteq N_G(K)\text{Ker}(\chi)$ for any finite subgroup $K$ of $G$. This is equivalent to $G = N_G(K)\text{Ker}(\chi)$.

Proof. Assume first that $G_\chi$ conjugates finite subgroups and consider a finite subgroup $K$ of $G$. Then, for any $m \in G_\chi$ if we put $K_1 := K^m \leq G$, we have $mK_1 = Km$ thus $K_1 = K'$ for some $t \in G_\chi$ invertible, in particular $t \in \text{Ker}(\chi)$. Since $m t^{-1} \in N_G(K)$ we get $m \in N_G(K)t \subseteq N_G(K)\text{Ker}(\chi)$, so $G_\chi \subseteq N_G(K)\text{Ker}(\chi)$.
Conversely, assume $G_\chi \subseteq N_G(K)\text{Ker}(\chi)$ and let $K, K_1 \leq G_\chi$ be finite subgroups such that $mk_1 = Km$ for $m \in G_\chi$. Put $m = st$ with $s \in N_G(K)$ and $t \in \text{Ker}(\chi)$, then $t \in G_\chi$ is invertible and $K' = K^m = K_1$.

In addition note that $G = G_\chi \cup G_\chi^{-1}$ and $N_G(K)\text{Ker}(\chi)$ is a subgroup of $G$, so if $G_\chi \subseteq N_G(K)\text{Ker}(\chi)$ we get $G = N_G(K)\text{Ker}(\chi)$.

\[ \square \]

**Lemma 3.4.** Let $\chi: G \to \mathbb{R}$ be a non-zero character, $\tilde{G} \leq G$ a subgroup and $N$ a normal subgroup of $G$ with $N \subseteq \text{Ker}(\chi) \cap \tilde{G}$. Assume that $\tilde{G}_\chi \subseteq \tilde{N}_G(K)N$ for every finite subgroup $K$ of $\tilde{G}$. Then $\tilde{G}_\chi$ conjugates finite subgroups.

**Proof.** As

\[ \tilde{G}_\chi \subseteq \tilde{N}_G(K)N \cap \tilde{G} \subseteq \tilde{N}_G(K)N \subseteq \tilde{N}_G(K)(\text{Ker}(\chi) \cap \tilde{G}) \]

it suffices to use Lemma [3.3] \[ \square \]

**Lemma 3.5.** Let $M = G_\chi$. Then for all finite subgroups $K$ and $H$ of $M$, $[M/K/M/H]$ is finitely generated as $W_MK$-set if and only if for every finite $K \leq M$ one of the following conditions holds:

1. $\chi(N_G(K)) = 0 \Leftrightarrow N_G(K) \subseteq \text{Ker}(\chi)$;
2. $\chi(N_G(K)) \simeq \mathbb{Z}$ i.e. $N_G(K)\text{Ker}(\chi)/\text{Ker}(\chi)$ has torsion-free rank 1;
3. $\chi(N_G(K)) = \chi(G)$ i.e. $N_G(K)\text{Ker}(\chi) = G$.

**Proof.** Let $K_1, \ldots, K_r$ be the subgroups in the decomposition of Lemma [2.7]. Note that these are precisely the subgroups of $M$ which are conjugated to $K$ by an element lying in $M$. Choose for each of them some $m_i \in M$ with $K^m_i = K_i$. Then $[M/K/M/H] = \bigcup_{1 \leq i \leq r}\{mH \mid K^m_i = K^m_i\}$. Thus the set $[M/K/M/H]$ is finitely generated over $W_MK$ if and only if for every $1 \leq i \leq s$ the set $(N_G(K)m_i) \cap M$ is finitely generated over $N_M(K) = N_G(K) \cap M$ via left multiplication. This is equivalent to $\inf\{\chi(g)|g \in N_G(K), gm_i \in G\}$ being attained which is equivalent to $\inf\{\chi(g)|g \in N_G(K), \chi(g) \geq -\chi(m_i)\}$ being attained. Note that this is the case if one of the conditions (i), (ii) or (iii) holds.

Let $m_0 \in G_\chi$. Suppose that $[M/K/M/H]$ is finitely generated as $W_MK$-set for $H = K^{m_0}$ and that neither of the conditions (i) and (ii) hold. Then the restriction of $\chi$ on $N_G(K)$ is a non-discrete non-zero real character, hence $\chi(N_G(K))$ is a dense subset of $\mathbb{R}$. Then $[M/K/M/H] = \{mH \mid K^m \subseteq mH = mK^{m_0}\} = \{mH \mid K^m \subseteq K^{m_0}\} = \{mH \mid K^m = K^{m_0}\}$ i.e. $s = 1$ and $m_1 = m_0$ and the above infimum is attained if and only if $-\chi(m_0) \in \chi(N_G(K))$ i.e. $\chi(G) \subseteq \chi(N_G(K))$. Since $N_G(K)$ is a group this is equivalent to $\chi(G) = \chi(N_G(K))$ i.e. $G = N_G(K)\text{Ker}(\chi)$.

\[ \square \]

**Corollary 3.6.** Let $N$ be the subgroup of $G$ that contains the commutator $G'$ and such that $N/G'$ is the torsion part of $G/G'$. Then the assumptions of Lemma [3.5] hold for every non-zero character $\chi: G \to \mathbb{R}$ if for every finite subgroup $K$ of $G$ one of the following conditions holds:

1. $N_G(K) \subseteq N$;
2. $N_G(K)N/N \simeq \mathbb{Z}$;
3. $N_G(K)N = G$.

**Remark 3.7.** For different $K$ we may need different conditions from the list above.

**Proof.** Take a character $\chi_0: G \to \mathbb{R}$ with $\text{Ker}(\chi_0) = N$. Then if Lemma [3.5] holds for any character $\chi$ it holds for $\chi = \chi_0$ and we are done.
For the converse let \( \chi : G \to \mathbb{R} \) be an arbitrary non-zero character. Suppose \( N_G(K) \subseteq N \). Then \( N_G(K) \subseteq N \subseteq \text{Ker}(\chi) \). If \( N_G(K)N/\mathbb{Z} \) then since \( \chi(N) = 0 \) we get that \( \chi(N_G(K)) \) is cyclic i.e. is either zero or \( \chi(N_G(K)) \simeq \mathbb{Z} \). Finally if \( N_G(K)N = G \), applying \( \chi \) we get \( \chi(N_G(K)) = \chi(G) \).

**Lemma 3.8.** Let \( M = G_{\chi} \). Then \( M \) has finitely many conjugacy classes of finite subgroups if and only if the following two conditions hold

1. \( N_G(K)\text{Ker}(\chi) \) has finite index in \( G \) for every finite subgroup \( K \);
2. \( G \) has finitely many conjugacy classes of finite subgroups.

**Proof.** Suppose first that \( M \) has finitely many conjugacy classes of finite subgroups (see Definition 2.4). Then since any finite subgroup of \( G \) lies in \( M \) (ii) follows immediately. Let \( K_1, \ldots, K_n \) be representatives of the conjugacy classes of finite subgroups in \( G \). Then for each \( i \), the \( G \)-orbit (via right conjugation) generated by \( K_i \) is finitely generated over the subgroup of invertible elements of \( G \), i.e. \( \text{Ker}(\chi) \). This is equivalent to the existence of a finite set \( m_1, \ldots, m_{i,j} \) such that \( G = \bigcup_{1 \leq i \leq j} N_G(K_i)\text{Ker}(\chi)m_j \). The last is equivalent to \( N_G(K)\text{Ker}(\chi) \) having finite index in \( G \).

The converse follows by repeating the above argument backwards. \( \square \)

4. **Some General Facts About Finite Index Extensions**

Assume a group \( T \) acts by conjugation on a finitely generated group \( G \). This induces a right action of \( T \) on \( \text{Hom}(G, \mathbb{R}) \) given by:

\[
\chi^t(g) := \chi(g^{t^{-1}}).
\]

Moreover, this action leaves \( \Sigma^n(G, \mathbb{Z}) \) setwise fixed for any \( n \).

**Lemma 4.1.** Let \( G \) be a finitely generated group with a finite index subgroup \( H \). Then:

1. For \( v_1, v_2 \in \text{Hom}(G, \mathbb{R}) \), \( v_1 = v_2 \) if and only if \( v_1|_H = v_2|_H \).
2. If \( G = K \ltimes H \) for some (finite) \( K \), the characters of \( H \) that can be extended to \( G \) are precisely those in the fixed points \( \text{Hom}(H, \mathbb{R})^G \).

**Proof.** For i), note that for any \( g \in G \), there is some \( n > 0 \) with \( g^n \in H \). Then, if \( v_1|_H = v_2|_H \),

\[
v_1(g^n) = v_1(g^n) = v_2(g^n) = n v_2(g).
\]

And for ii) observe that \( K \leq \text{Ker}(\chi) \) for any character \( \chi : G \to \mathbb{R} \) thus \( \chi|_H \in \text{Hom}(H, \mathbb{R})^G \). Conversely, let \( v \in \text{Hom}(H, \mathbb{R})^G \) and define \( \chi : G \to \mathbb{R} \) by \( \chi(kh) := v(h) \) for \( k \in K, h \in H \). This is a well defined character of \( G \) that extends \( v \). \( \square \)

5. **Examples**

We will see later on that property (i) from Lemma 3.8 i.e.

\[
|G : N_G(K)| < \infty \text{ for any character } \chi : G \to \mathbb{R}, \text{ for any finite } K \leq G
\]

holds for all virtually soluble groups of type \( FP_\infty \) and finite extensions of the Thompson group \( F \) (see Theorem 7.6 and Theorem 8.3). Note that this is equivalent to \( |G : N_G(K)(G,G)| < \infty \). We will discuss these examples in more details in the last two sections of the paper.
Example 5.1. Using right angled Artin groups, it is not difficult to construct groups for which condition (3) does not hold true. Let $K = C_2$ and $L$ be the simplicial complex having four vertices labeled $1, 2, 3$ and $4$ and edges joining the vertices labeled $\{1, 4\}$; $\{2, 4\}$ and $\{3, 4\}$. Let $A_L$ be the associated right angled Artin group, i.e., the group with presentation
\[ \langle g_1, g_2, g_3, g_4 \mid [g_1, g_4], [g_2, g_4], [g_3, g_4] \rangle \]
and consider the action of $K$ on $L$ given by swapping the vertices labeled $1$ and $2$. This yields and action of $K$ on $A_L$ and we may form the semidirect product
\[ G = K \rtimes A_L. \]
Let $L^K$ denote the fixed point subcomplex, i.e., the subcomplex of $L$ consisting of the vertices $3, 4$ with an edge joining them. Then using Theorem 2 in [14] (due to Crisp) we get $N_G(K)/K \cong C_{A_L}(K) = A_L^K = \langle g_3, g_4 \rangle$.

Now, consider the character $\chi : G \to \mathbb{R}$ such that $\chi(g_1) = 1 = \chi(g_2)$, $\chi(g_3) = \alpha$, $\chi(g_4) = \beta$ so that $\langle 1, \alpha, \beta \rangle$ is a rank $3$ subgroup of $(\mathbb{R}, +)$. Then $\chi(N_G(K)\ker(\chi)) = \chi(N_G(K)) = \langle \alpha, \beta \rangle$ and $\chi(G) = \langle 1, \alpha, \beta \rangle$, so $|G: N_G(K)\ker(\chi)|$ is not finite.

Example 5.2. Finally we consider an example where (3) holds but for some character $\chi$ we have $G \not\cong N_G(K)\ker(\chi)$. This is equivalent to $\chi(G) \neq \chi(N_G(K))$.

Consider $G = K \rtimes (b_0, b_1, b_2, b_3)$ with $K = C_2$ generated by $t$ swapping $b_0, b_1$ and $b_2, b_3$, where $\langle b_0, b_1, b_2, b_3 \rangle \simeq \mathbb{Z}_4$. Let $a_0 = b_0b_1$, $a_1 = b_2b_3$, $a_2 = b_0b_1^{-1}$, $a_3 = b_2b_3^{-1}$ and note that $a_2, a_3 \in G'$. Then $N_G(K) = C_{G}(K) = K \times \langle a_0, a_1, a_2 \rangle$, hence $\chi(N_G(K)) = \chi(a_0) = 2\chi(b_0)$, $\chi(a_1) = 2\chi(b_2)$, $\chi(a_2) = 2\chi(b_0)$, $\chi(a_3) = 2\chi(b_2)$, $\chi(G)$.

6. BREEDON SIGMA THEORY

Let
\[ S(G) := Hom(G, \mathbb{R}) \setminus \{0\} / \sim \]
where $\sim$ is the equivalence relation given by $\chi_1 \sim \chi_2$ if $\chi_1 \in \mathbb{R}_{>0}\chi_2$. Write $[\chi]$ for the equivalence class of $\chi$.

Definition 6.1. Let $A$ be an $\mathcal{O}_\mathbb{F} G$-module and $[\chi] \in S(G)$. Then we say that $[\chi] \in \Sigma^m(G, A)$ if there is a subgroup $\bar{G}$ of finite index in $G$ that contains all finite subgroups of $G$, $G' \leq \bar{G}$, $M = \bar{G}_\chi$ conjugates finite subgroups and $A$ is $FP_m$ as $\mathcal{O}_\mathbb{F} M$-module. Observe that in this definition $\bar{G}$ might depend on $\chi$.

Theorem 6.2. Let $G$ be a finitely generated group. Then $[\chi] \in \Sigma^m(G, \mathbb{Z})$ if and only if there is a subgroup $\bar{G}$ of finite index in $G$ with $G' \leq \bar{G}$ and a family $\{H_1, \ldots, H_s\}$ of finite subgroups of $\bar{G}$ such that for any finite subgroup $K$ of $G$ we have $K \leq \bar{G}$ and the following three conditions hold:

1. $N_{\bar{G}}(K)(\ker(\chi) \cap \bar{G}) = \bar{G}$;
2. $\chi(N_G(K)) \neq 0$ and $[\chi|_{N_G(K)}] \in \Sigma^m(N_G(K), \mathbb{Z})$;
3. there is an element $m \in \bar{G}_\chi$ such that $Km \subseteq mH_i$ for some $i = 1, \ldots, s$.

Remark 6.3. Since $C_G(K)$ has finite index in $N_G(K)$ and by [19] Thm. 9.3] (see Theorem [8.2] condition 2 is equivalent to condition

2b). $\chi(C_G(K)) \neq 0$ and $[\chi|_{C_G(K)}] \in \Sigma^m(C_G(K), \mathbb{Z})$.

Proof. Note that by Lemma [3.3] condition 1 is equivalent to $M = \bar{G}_\chi$ conjugates finite subgroups. By Lemma [2.3] condition 3 is equivalent to $\mathbb{Z}$ is $FP_0$ as $\mathcal{O}_\mathbb{F} M$-module.
By Corollary 2.13 \( \mathbb{Z} \) is FP as \( \mathcal{O} \)-module if and only if condition 3 holds and \( \mathbb{Z} \) is FP as left \( \mathbb{Z} \)-module for every finite subgroup \( K \). This is equivalent to

\[ \mathbb{Z} \text{ is of type } FP_m \text{ as left } \mathbb{Z}N_m(\mathcal{O})-\text{module}. \]

Note that \( N_m(G) = N_G(\mathcal{O}) \) for every finite subgroup \( G \). By condition 1 we have that the restriction of \( \chi \) on \( N_G(\mathcal{O}) \) is non-zero, hence \( ||\) is equivalent to

\[ [\chi|_{N_G(\mathcal{O})}] \in \Sigma^m(N_G(\mathcal{O}), \mathbb{Z}). \]

Since \( N_G(\mathcal{O}) \) has finite index in \( N_G(\mathcal{O}) \) by 19 Thm. 9.3 \( \mathcal{O} \) is equivalent to \( [\chi] \in \Sigma^m(N_G(\mathcal{O}), \mathbb{Z}). \)

**Lemma 6.4.** Let \( G \) be a finitely generated group. If \( \Sigma^m(G, \mathcal{O}) \neq \emptyset \) then \( \mathcal{O} \) is Bredon FP- \( m \).

**Proof.** By Lemma 2.2 we have to show that there are finitely many \( G \)-orbits under conjugation of finite subgroups in \( G \) and \( N_G(\mathcal{O}) \) is of type \( FP_m \) for every finite subgroup \( K \) of \( G \). Let \( [\chi] \in \Sigma^m(G, \mathcal{O}) \). Then condition 3 from Theorem 5.2 shows that any finite subgroup \( K \) of \( G \) is inside \( H^g \) for some \( g \in G_\chi \) and \( 1 \leq i \leq s \), hence there are finitely many \( G \)-orbits of finite subgroups in \( G \).

If \( N_G(\mathcal{O}) \chi \) is of type \( FP_m \) then \( N_G(\mathcal{O}) \) is of type \( FP_m \). Hence \( \mathcal{O} \) is Bredon FP- \( m \).

**Remark 6.5.** Let \( G \) be a finitely generated group. Then \( \Sigma^m(G, \mathcal{O}) \subseteq \Sigma^m(G, \mathbb{Z}) \). To see it, observe that we may assume \( \Sigma^m(G, \mathcal{O}) \neq \emptyset \) and it suffices to consider the case when \( K \) is the trivial group in part 2 from Theorem 6.2.

**Theorem 6.6.** Suppose that \( G \) is a finitely generated group and has finitely many conjugacy classes of finite subgroups. Then \( [\chi] \in \Sigma^m(G, \mathbb{Z}) \) if and only if there is a subgroup \( \tilde{G} \) of finite index in \( G \) that contains the commutator subgroup \( G' \) such that for every finite subgroup \( K \) of \( G \) we have \( K \leq \tilde{G} \) and

1. \( N_{G'}(\ker(\chi) \cap \tilde{G}) = \tilde{G} \);
2. \( \chi(\ker(\chi)) \neq 0 \) and \( [\chi|_{N_G(\mathcal{O})}] \in \Sigma^m(N_G(\mathcal{O}), \mathbb{Z}). \)

**Remark 6.7.** As before condition 2 can be substituted with condition 2b) from Remark 6.3. By Lemma 6.4 if \( \Sigma^m(G, \mathcal{O}) \neq \emptyset \) then \( G \) has finitely many conjugacy classes of finite subgroups.

**Proof.** Assume that there is \( \tilde{G} \) such that conditions 1 and 2 hold. Since \( G \) has finitely many conjugacy classes of finite subgroups, the same holds for \( \tilde{G} \). Let \( H_1, \ldots, H_s \) be representatives of the finitely many conjugacy classes of finite subgroups in \( \tilde{G} \). We claim that condition 1 from Theorem 6.2 implies condition 3 from Theorem 6.2. Indeed condition 3 is equivalent to every finite subgroup \( K \) of \( G \) being a subgroup of \( H_i^g \) for some \( g \in G_\chi \) and \( 1 \leq i \leq s \). Note that \( K \leq H_i^g \) for some \( t \in \tilde{G} = N_G(H_i)(\ker(\chi) \cap \tilde{G}) \), so \( t = xy \), \( x \in N_G(H_i) \), \( y \in \ker(\chi) \cap \tilde{G} \leq H_i^g \), and hence \( H_i^g = H_i^y = H_i^g \).

The following is a Bredon version of [5] Thm. B. Recall that \( S(G, H) \) consists of the classes of all those characters vanishing on \( H \).

**Theorem 6.8.** Let \( H \) be a subgroup of a finitely generated group \( G \) that contains the commutator subgroup \( G' \) such that \( G/H \) is torsion-free and non-trivial.
Assume that \( \mathbb{Z} \) is Bredon FP\(_{m} \) as \( \mathcal{O}_{\mathcal{F}} \)-\( G \)-module. Then \( \mathbb{Z} \) is Bredon FP\(_{m} \) as \( \mathcal{O}_{\mathcal{F}} \)-\( H \)-module if and only if \( S(G, H) \subseteq \Sigma^{m}(G, \mathbb{Z}) \).

**Proof.** 1. Suppose that \( \mathbb{Z} \) is Bredon FP\(_{m} \) as \( \mathcal{O}_{\mathcal{F}} \)-\( H \)-module. Then by Lemma 2.2

- a1) there are finitely many conjugacy classes of finite subgroups in \( H \);
- b1) for any finite subgroup \( K \) of \( H \) the group \( N_{H}(K) \) is of type FP\(_{m} \).

Since \( G, H \) are FP\(_{m} \) there are finitely many conjugacy classes of finite subgroups in both \( G, H \) and every \( G \)-orbit (of finite groups under conjugation) splits into finitely many \( H \)-orbits, hence for every finite subgroup \( K \) of \( G \)

\[
N_{G}(K)H \text{ has finite index in } G.
\]

Define

\[
\tilde{G} = \cap N_{G}(K)H,
\]

where the intersection is over representatives of the \( G \)-orbits of conjugacy classes of finite subgroups in \( G \). Thus the intersection is finite, \( \tilde{G} \) has finite index in \( G \) and contains \( H \), hence \( \tilde{G} \) contains all the finite subgroups of \( G \) and the commutator subgroup \( G' \).

Let \( \chi \in S(G, H) \) i.e. \( H \subseteq \text{Ker}(\chi) \). By Lemma 3.4 applied for \( N = H \), \( \tilde{G}_{\chi} \) conjugates finite subgroups. Then condition 1 from Theorem 6.6 holds and \( \tilde{G} \) is global i.e. \( \tilde{G} \) does not depend on \( \chi \).

Note that \( N_{H}(K) = N_{G}(K) \cap H \), so \( N_{G}(K) \cap N_{H}(K) \) is abelian. By condition b1) and [5] Thm. B] we have that every non-zero real character \( \tilde{\chi} : N_{G}(K) \to \mathbb{R} \) such that \( \tilde{\chi}(N_{H}(K)) = 0 \) represents an element of \( \Sigma^{m}(N_{G}(K), \mathbb{Z}) \). In particular this holds for \( \tilde{\chi} \) the restriction of \( \chi \) to \( N_{G}(K) \), hence condition 2 from Theorem 6.6 holds.

Note that since \( \chi(H) = 0 \) and \( |G : N_{G}(K)H| < \infty \) we have \( \chi(N_{G}(K)) \neq 0 \). Then by Theorem 6.6 \( [\chi] \in \Sigma^{m}(G, \mathbb{Z}) \).

2. Conversely suppose that

\[
S(G, H) \subseteq \Sigma^{m}(G, \mathbb{Z}).
\]

Then by Theorem 6.2 for every \( [\chi] \in S(G, H) \):

- a2) there is a subgroup \( \tilde{G} \) of finite index in \( G \) that contains the commutator \( G' \) and contains every finite subgroup \( K \) of \( G \) and \( N_{G}(K)(\text{Ker}(\chi) \cap \tilde{G}) = \tilde{G} \);
- b2) for any finite subgroup \( K \) of \( G \) we have \( \chi(N_{G}(K)) \neq 0 \) and \( [\chi|_{N_{G}(K)}] \in \Sigma^{m}(N_{G}(K), \mathbb{Z}) \). In particular \( N_{G}(K) \) is of type FP\(_{m} \).

Since \( \Sigma^{m}(G, \mathbb{Z}) \neq \emptyset \), by Lemma 6.4 \( G \) has finitely many conjugacy classes of finite subgroups. By a2) \( N_{G}(K)\text{Ker}(\chi) \) has finite index in \( G \), hence every \( G \)-orbit of finite subgroups (i.e. \( \{K' \mid K' \in G\} \)) splits into finitely many \( \text{Ker}(\chi) \)-orbits. Choose \( \chi \) such that \( H = \text{Ker}(\chi) \). Then every \( G \)-orbit of finite subgroups splits into finitely many \( H \)-orbits, so \( H \) has finitely many conjugacy classes of finite subgroups i.e. condition a1) holds.

It remains to show that condition b1) holds. Fix one finite subgroup \( K \) of \( G \). By b2) \( N_{G}(K) \) is of type FP\(_{m} \). Recall that \( N_{G}(K) / N_{H}(K) \) is abelian. Let \( \mu : N_{G}(K) \to \mathbb{R} \) be a non-zero real character such that \( \mu(N_{H}(K)) = 0 \). Then \( \mu \) can be extended to a real character \( \mu_{1} \) of \( N_{G}(K)H \) that is zero on \( H \). Since \( G' \subseteq H \) we see that \( \mu_{1} \) is extendable to a real character \( \chi \) of \( G \). Thus by condition b2) \( N_{G}(K)\chi = N_{G}(K)\mu \) is of type FP\(_{m} \). Then by the original Bieri-Renz criterion [5] Thm. B] \( N_{H}(K) \) is of type FP\(_{m} \).
Example 6.9. Let $G$ be a polycyclic group. Then $\mathbb{Z}$ is Bredon $FP_\infty$ as $O_\neq G$ module. Let $H$ be the subgroup of $G$ that contains the commutator and such that $H/G'$ is the torsion part of $G/G'$. Since $H$ is polycyclic, $\mathbb{Z}$ is Bredon $FP_\infty$ as $O_\neq H$ module. So by the previous theorem

$$\Sigma^m(G, \mathbb{Z}) = S(G, H) = S(G).$$

Example 6.10. Leary-Nucinkis have constructed an example of a group which is of ordinary type $FP_\infty$ but not Bredon $FP_\infty$ (see [14]). Their example is obtained as a finite index extension of a Bestvina-Brady group $B_L$, where $L$ is certain flag complex on which the alternating group of degree 5, $K = A_5$ acts. Consider the associated right angled Artin group $A_L$, then $K$ also acts on $L$ and we may form $G = K \times A_L$. The map $\chi : A_L \to \mathbb{Z}$ which sends all the generators in the standard right-angled Artin presentation of $A_L$ to the identity is a (discrete) character of $G$ which by Lemma 6.4 can be lifted to a character $\chi_0$ of $G$, then $\text{Ker}(\chi) = B_L$ and $\text{Ker}(\chi_0) = K \times B_L$ is Leary-Nucinkis’ example. Then Theorem 6.8 implies that $[\chi_0] \notin \Sigma^m(G, \mathbb{Z})$, however $[\chi] \in \Sigma^m(G, \mathbb{Z})$ by the version of this result for ordinary characters, see [3]. Thm. B. Note that by [14], $L^K = \emptyset$ which implies that $K = N_G(K)$, so here both conditions from Theorem 6.6 fail.

Theorem 6.11. Suppose that $\Sigma^m(G, \mathbb{Z}) \neq \emptyset$. Then $\Sigma^m(G, \mathbb{Z})$ is open in $S(G)$ if and only if $N_G(K)G'$ has finite index in $G$ for every finite subgroup $K$.

Remark 6.12. It will follow from the results in the last two sections of this paper that the condition $[G : N_G(K)G'] < \infty$ holds for virtually soluble groups of type $FP_\infty$ and for finite extensions of the Thompson group $F$.

Proof. Let $N/G'$ be the torsion part of the abelianization $G/G'$. By Lemma 6.4 $G$ has finitely many conjugacy classes of finite subgroups.

Suppose first that $\Sigma^m(G, \mathbb{Z})$ is open in $S(G)$ and let $[\chi] \in \Sigma^m(G, \mathbb{Z})$. Then there is $[\chi_0] \in \Sigma^m(G, \mathbb{Z})$ that is “close” to $[\chi]$ and such that $\text{Ker}(\chi_0) = N$. Then condition 1 from Theorem 6.6 implies that there is a subgroup of finite index $\tilde{G}$ in $G$ such that $N_{\tilde{G}}(K) \cap \tilde{G} = \tilde{G}$, hence $N_G(K)N$ has finite index in $G$ and since $N/G'$ is finite $N_{\tilde{G}}(K)G'$ has finite index in $G$.

For the converse assume that $N_G(K)G'$ has finite index in $G$ for every finite subgroup $K$. Then $[G : N_G(K)N] < \infty$. Let $\tilde{G} = \cap_k N_G(K)N$ where the intersection is over representatives of conjugacy classes of finite subgroups in $G$, thus the intersection is finite and $\tilde{G}$ has finite index in $G$. Note that $\tilde{G} = N_{\tilde{G}}(K)N$. Then by Lemma 3.3 and Lemma 3.4 condition 1 from Theorem 6.6 holds for every character $\chi$ and furthermore $\chi(N_G(K)) \neq 0$. Observe that since $N_G(K)N$ has finite index in $G$ we have $S(G) \subseteq S(N_G(K)N)$ and $S(G) = S(N_G(K), N \cap N_G(K)) \subseteq S(N_G(K))$.

Since $\Sigma^m(N_G(K), \mathbb{Z})$ is an open subset of $S(N_G(K))$ we deduce that condition 2 from Theorem 6.6 is an open condition for a fixed finite subgroup $K$ i.e. if it holds for one character holds for a neighbourhood. The fact that there are finitely many conjugacy classes $K$ of finite subgroups in $G$ completes the proof.

7. Finite extensions of the Thompson group

In this section we use the notation of [8], [11]. So we denote by $F_{\infty, \mu}$ the group of PL increasing homeomorphisms $f$ of $\mathbb{R}$ acting on the right such that the set $X_f$ of break points of $f$ is a discrete subset of $\mathbb{Z} \left[\frac{1}{\mu}\right]$, $f(X_f) \subseteq \mathbb{Z} \left[\frac{1}{\mu}\right]$ and slopes are integral.
powers of $n$. Furthermore, there are integers $i$ and $j$ (depending on $f$) with

$$(x)f = \begin{cases} x + i(n-1) & \text{for } x > M, \\ x + j(n-1) & \text{for } x < -M \end{cases}$$

for sufficiently large $M$ (depending on $f$ again).

**Definition 7.1.** Let $n \geq 2$ and let $t_0 \in \mathbb{R}$. Set

$$F_{n,[0,\infty)} = \{ f \mid f \text{ is the restriction to } [t_0,\infty) \text{ of } \tilde{f} \in F_{n,\infty}, \tilde{f}(t_0) = t_0 \},$$

$$F_{n,(-\infty,t_0]} = \{ f \mid f \text{ is the restriction to } (-\infty,t_0] \text{ of } \tilde{f} \in F_{n,\infty}, \tilde{f}(t_0) = t_0 \}.$$

Let

$$\mu_1, \mu_2 : F_{n,[0,\infty)} \to \mathbb{R}$$

be the characters given by $\mu_1(f) = \log_n((t_0)f')$ and $\mu_2(f) = -i$ if $(x)f = x + i(n-1)$ for $x > 0$ and let

$$\nu_1, \nu_2 : F_{n,(-\infty,t_0]} \to \mathbb{R}$$

be the characters given by $\nu_1(f) = \log_n((t_0)f')$, $\nu_2(f) = -j$ where $(x)f = x + j(n-1)$ for $x < 0$.

The following lemma is a correction of Lemma 4.7 from [11]. Note that in [11] though not explicitly stated the $\Sigma$-invariants are defined via right actions as both Proposition 3.3 and Theorem 3.4 there work only in this case.

However in this paper all modules are left ones, so we stick to $\Sigma$-invariants defined via left actions. Generally moving to a definition of the $\Sigma$-invariants from right actions to left actions changes only the sign of the invariant i.e. we get the antipodal set.

**Lemma 7.2.** $\Sigma^1(F_{n,[0,\infty)}) = \{-[\mu_1],[-\mu_2]\}$ and $\Sigma^1(F_{n,(-\infty,t_0]}) = \{-[\nu_1],[\nu_2]\}$.

**Proof.** As shown in Lemma 4.7 in [11], the map $\mu : [0,\infty) \to [0,n-1]$ of [8] Lemma 2.3.1 induces by conjugation an isomorphism from $F_{n,[0,\infty)}$ to a subgroup of the group of piecewiselinear homeomorphisms of the interval $[0,n-1]$. Note that we can assume that $t_0$ is an element of any fixed interval $[s,s+n-1]$ or $[s,s+n-1]$ since for $\delta : x \mapsto x + n - 1$ we have $\delta F_{n,[0,\infty)} \delta^{-1} = F_{n,(-1,\infty)}$. In particular we assume that $t_0 \in [0,n-1)$. The map $\mu$ was used in Lemma 4.7 from [11] together with the description of $\Sigma^1$ for groups of PL automorphisms of closed intervals [4] to calculate $\Sigma^1(F_{n,[0,\infty)})^\nu$. Adding the extra minus signs explained in the paragraph before Lemma 7.2 we get that $\Sigma^1(F_{n,[0,\infty)}) = \{-[\mu_1],[-\mu_2]\}$.

Consider now the group $F_{n,(-\infty,t_0]}$. If we want to do the same as for the group $F_{n,[0,\infty)}$, we first have to modify $\mu$ by composing it with the map $x \mapsto -x$ so that we get $\mu^-(\infty,0) \to [0,n-1]$. Here we need to assume $-n+1 < t_0 \leq 0$, exactly as for the argument before we needed $0 \leq t_0 < n-1$. This has the effect that now we get $\Sigma^1(F_{n,(-\infty,t_0]})^\nu = \{-[\nu_1],[\nu_2]\}$. Thus the correct statement of [11] Lemma 4.9 using the definition of $\Sigma$ via right actions there is $\Sigma^1(F_{n,(-\infty,t_0]})^\nu = \{[\nu_1],[-\nu_2]\}$, slightly different than what is stated in [11] Lemma 4.9 as $\{[\nu_1],[\nu_2]\}$. However, this does not affect the main results of [11], since with the notation of [11] Lemma 4.11, we get that the map $\tilde{\phi}^*$ swaps $[\mu_1]$ with $[\nu_1]$ and $[\mu_2]$ with $[-\nu_2]$ and in [11] the fact that $\tilde{\phi}^*$ swaps $[\mu_1]$ with $[\nu_1]$ was used and this holds in our corrected version. □
From now on, we consider the case $n = 2$ only and put $F := F_{2, \infty}$. We consider the following two characters of $F$. Let $f \in F$ be such that $(x)f = x + i$ when $x > 0$ and $(x)f = x + j$ for $x < 0$ and define

$$\chi_1(f) = j, \quad \chi_2(f) = -i.$$

Note that as $F/F'$ has rank 2, $S(F) = \{ [a\chi_1 + b\chi_2] \mid a, b \in \mathbb{R} \}$.

Let $I$ be the unit interval and $\phi : I \to \mathbb{R}$ be the PL-homeomorphism with breakpoints $1/2^i, 1 - 1/2^j$ for $i, j > 0$ such that $(1/2^i)\phi = -i + 1, (1 - 1/2^j)\phi = j - 1$. Conjugating with $\phi$ yields an isomorphism from $F_{2, \infty}$ to the Thompson group of PL-homeomorphisms of $I$ which we denote $F_I$. Using this isomorphism we get for $F_I$ the characters $\alpha_i(h) = \chi_1(h^{-1}h\phi)$ for $i = 1, 2$ and one easily checks that $\alpha_i(h) := \log_2((i - 1)h^i)$. Therefore by Theorem A in [3] (see also [4]) after sign change,

$$\Sigma^1(F) = S(F) \setminus \{-[\chi_1], -[\chi_2]\},$$

$$\Sigma^\infty(F, \mathbb{Z})^c = S(F) \setminus \Sigma^2(F, \mathbb{Z}) = \text{conv}_{\leq 2}\{-[\chi_1], -[\chi_2]\} = \{[a\chi_1 + b\chi_2] \mid a \leq 0, b \leq 0, (a, b) \neq (0, 0)\}.$$

**Proposition 7.3.** Let $G = K \times F$ with $K$ finite such that $C_K(K) < F$. Then $S(G) = \{[v], [-v]\}$ with $v : G \to \mathbb{R}$ the only character such that $v|_F = \chi_1 + \chi_2$.

**Proof.** By the same argument of [11] Theorem C, there is a subgroup $K_0 \leq K$ of index 2 acting trivially on $F$. Then, $KF/K_0 \cong (K/K_0) \times F$, and the action of $K/K_0$ on $F$ is given by conjugation with a decreasing homeomorphism $h$ of $\mathbb{R}$ such that $h^2 = id$ (see [11], Lemma 4.1). Let $[v] \in S(G)$. By Lemma 4.1 $v|_F \in \text{Hom}(F, \mathbb{R})^K = \text{Hom}(F, \mathbb{R})^{K/K_0}$. The fact that $h$ is decreasing implies that the induced action of $K/K_0$ in $S(F)$ swaps $[\chi_1]$ and $[\chi_2]$, this also follows taking into account that $\Sigma^1(F, \mathbb{Z})^c = \{-[\chi_1], -[\chi_2]\}$. Therefore

$$\Sigma^\infty(F) = \{[\chi_1 + \chi_2], [-\chi_1 - \chi_2]\}$$

and the claim follows by Lemma 4.1. □

As a consequence, we get

**Lemma 7.4.** Let $G = K \times F$ with $K$ finite such that $C_K(K) < F$. Then $\Sigma^\infty(G, \mathbb{Z}) = \{[v]\}$ with $v|_F = \chi_1 + \chi_2$.

**Proof.** It follows by [19] Thm. 9.3 (see Theorem 8.2), Proposition 7.3 and (7). □

**Theorem 7.5.** Let $G = K \times F$ with $K$ finite. Then

$$\Sigma^\infty(G, \mathbb{Z}) = \Sigma^\infty(G, \mathbb{Z}).$$

**Proof.** We only have to check that any $[\chi] \in \Sigma^\infty(G, \mathbb{Z})$ also lies in $\Sigma^\infty(G, \mathbb{Z})$. As by Corollary D of [11] we know that $G$ has only finitely many conjugacy classes of finite subgroups, all we have to do is to check whether $\chi$ satisfies the conditions of Theorem [6.6].

If $C_F(K) = F$, then $G = K \times F$ so both conditions from Theorem [6.6] are trivial (taking $\tilde{G} = G$).

So we may assume $C_F(K) < F$ thus by Lemma 7.4 $[v] = [\chi]$ and we may assume $\chi = v$, in particular it is discrete (all the characters of $G$ are). Fix

$$\tilde{G} = C_F(K)\text{Ker}(v).$$
Observe that any finite subgroup of $G$ is contained in $\text{Ker}(\nu)$, hence is contained in $\tilde{G}$. This means that the result will follow if we prove that $\tilde{G}$ has finite index in $G$ and for any finite $Q \leq G$, $N_G(Q) \not\leq \text{Ker}(\nu)$ and $[\nu]_{|N_G(Q)} \in \Sigma^\infty(N_G(Q), \mathbb{Z})$. If $Q$ acts trivially on $F$, then last two assertions are obvious. And in other case, arguing as in Proposition 7.3 we see that there is a $Q_0 \leq Q$ of index 2 acting trivially on $F$ so that the action of $Q/Q_0 = \langle \varphi \rangle$ on $F$ is given by conjugation with a decreasing homeomorphism $h$ of $\mathbb{R}$ such that $h^2 = id$. Note that $\chi_2^G = \chi_1$. Now, by [11, Thm. 4.14] there is an isomorphism

$$\rho : C_F(\varphi) \to F_{2, [t_0, \infty]}$$

where $t_0 \in \mathbb{R}$ is the only element such that $(t_0)h = t_0$ and $\rho$ sends $f$ to its restriction on $[t_0, \infty]$. Furthermore it was shown in [11, Thm. 7.3] that $t_0 \in \mathbb{Z}[\frac{1}{2}]$, hence $F_{2, [t_0, \infty]} \simeq F$. By Lemma 7.2 $I(F_{2, [t_0, \infty]})^C = [\mu_1, \mu_2]$ and since $F_{2, [t_0, \infty]} \simeq F$ and by (7)

$$[\mu_2] \in \Sigma^\infty(F_{2, [t_0, \infty]}).$$

Let $\mu : F_{2, [t_0, \infty]} \to \mathbb{R}$ be the character obtained by composing $\nu|_{C_F(\varphi)} \rho^{-1}$. Since $C_F(\varphi)$ has finite index in $N_G(Q)$ and by [19, Theorem 9.3] (see Theorem 8.2), we only have to check that $\mu \neq 0$ and $[\mu] \in \Sigma^\infty(F_{2, [t_0, \infty]})$. And to understand $\mu$ basically we only have to understand $\rho^{-1}$, which by [11, Theorem 4.14] sends $f \in F_{2, [t_0, \infty]}$ to the only $\tilde{f} : \mathbb{R} \to \mathbb{R}$ with $(x)f = (x)\tilde{f}$ for $x \in [t_0, \infty)$ and such that $\tilde{f}h = h\tilde{f}$. Assume that $(x)f = x + i$ for $i > 0$. Then as $\tilde{f} \in C_F(\varphi)$ and $\chi_2^G = \chi_1$ we have

$$\mu(f) = \nu(\tilde{f}) = \chi_1(\tilde{f}) + \chi_2(\tilde{f}) = \chi_2^G(\tilde{f}) + 2\chi_2(\tilde{f}) = -2i,$$

which means that $0 \neq [\mu] = [\mu_2] \in \Sigma^\infty(F_{2, [t_0, \infty]}, \mathbb{Z})$. In particular for $Q = K$ we get $\text{Ker}(\nu) < C_F(K)\text{Ker}(\nu) = \tilde{G}$ thus $[G : \tilde{G}] < \infty$. 

**Theorem 7.6.** Let $G$ be a finite extension of the R. Thompson group $F$. Then

$$\Sigma^\infty(G, \mathbb{Z}) = \Sigma^\infty(G, \mathbb{Z}).$$

**Proof.** By Corollary D of [11] there are finitely many conjugacy classes of finite subgroups in $G$, let $K_1, \ldots, K_s$ be representatives of these conjugacy classes. For $1 \leq i \leq s$ set $G_i = F_i \rtimes K_i$.

Let $[\chi] \in \Sigma^\infty(G, \mathbb{Z})$. We have to show that $[\chi] \in \Sigma^\infty(G, \mathbb{Z})$. Note that by [19, Thm. 9.3] (see Theorem 8.2) for $i \leq s$ we have $[\chi|_{G_i}] \in \Sigma^\infty(G_i, \mathbb{Z})$. By the proof of Theorem 7.3

$$[\chi|_{N_G(K_i)}] \in \Sigma^\infty(N_G(K_i), \mathbb{Z}).$$

Let $K$ be a finite subgroup of $G$, so $K = K_i^g$ for some $g, i$. Thus to establish the second condition of Theorem 6.6 it suffices to consider the case when $K = K_i$. Note that $[N_G(K_i) : N_{G_i}(K_i)] < \infty$. By (9) and Theorem 8.2 we get that

$$\chi(N_G(K_i)) \neq 0$$

and $[\chi|_{N_G(K_i)}] \in \Sigma^\infty(N_G(K_i), \mathbb{Z})$,

so the second condition of Theorem 6.6 holds.

Set

$$\tilde{G} = \cap_{1 \leq i \leq s}(C_F(K_i)\text{Ker}(\chi)).$$

Note that for $g \in G$ we have $C_F(K_i^g)\text{Ker}(\chi) = C_F(K_i^g)\text{Ker}(\chi) = C_F(K_i)\text{Ker}(\chi)$, so $\tilde{G}$ is the intersection of $C_F(K_i)\text{Ker}(\chi)$ where $K$ runs through all finite subgroups of $G$. We claim that $C_F(K_i)/(\text{Ker}(\chi) \cap G_i)$ has finite index in $G_i$, hence in $G$. Indeed if
$K_i$ acts non-trivially on $F$ this follows from the proof of Theorem 7.5 and the fact that $\left[\chi_{|G_i}\right] \in \Sigma^\infty(G_i, \mathbb{Z})$, so $\chi |G_i$ is the unique character of $G_i$ whose restriction on $F$ is $\chi_1 + \chi_2$. If $K_i$ acts trivially on $F$ we have $F \leq C_{G_i}(K_i)$, so $\left|G_i : C_{G_i}(K_i)(\ker(\chi) \cap G_i)\right| \leq \left|G_i : F\right| < \infty$. Thus $\tilde{G}$ has finite index in $G$. By Lemma 3.3 applied for the normal subgroup $N = \ker(\chi)$ of $G$ we get that $\tilde{G}_{\chi}$ conjugates finite subgroups, hence by Lemma 3.3 applied for the group $\tilde{G}$ the first condition of Theorem 6.6 holds.

8. Soluble groups of type $\text{FP}_\infty$

We recall some results that will be useful in this section.

Theorem 8.1. [18, Cor. 5.2] Let $G$ be a nilpotent-by-abelian group of type $\text{FP}_\infty$ then

$$\Sigma^\infty(G, \mathbb{Z})^c = \text{com} \Sigma^1(G, \mathbb{Z})^c$$

Theorem 8.2. [19, Thm. 9.3] Let $H$ be a subgroup of finite index in a finitely generated group $G$ and $\chi : G \to \mathbb{R}$ be a non-trivial character. Then $[\chi] \in \Sigma^\infty(G, \mathbb{Z})$ if and only if $[\chi]|H \in \Sigma^\infty(H, \mathbb{Z})$.

Theorem 8.3. [17, Thm. 2.4] Let $\Gamma$ be a virtually soluble group of type $\text{FP}_\infty$. Then there is only a finite number of conjugacy classes of finite subgroups of $\Gamma$.

Theorem 8.4. [17, Thm. 3.13] Let $G$ be a virtually soluble group of type $\text{FP}_\infty$ and $F$ be a finite group acting on $G$. Then $C_G(F)$ is of type $\text{FP}_\infty$ and is finitely presented.

We outline the main steps in the proof of Theorem 8.4. Recall for a $\mathbb{Z}Q$-module $A$ the invariants $\Sigma_\chi(Q) = \{[X] \in S(Q)|A \text{ is finitely generated as } \mathbb{Z}Q\text{-module}\}$ and $\Sigma_\chi(Q)^c = S(Q) \setminus \Sigma_\chi(Q)$. For a subset $M$ of $S(Q)$ we denote by $\text{dis}M$ the discrete points of $M$.

1. By the classification of soluble groups of type $\text{FP}_\infty$ started in [9], and finished in [12], such groups are virtually torsion-free, constructible. Hence they are finitely presented and nilpotent-by-abelian-by-finite. So it suffices to assume that $G$ is nilpotent-by-abelian.

2. For nilpotent-by-abelian groups $G$ it is known that $G$ is of type $\text{FP}_\infty$ if and only $\Sigma^1(G, \mathbb{Z})^c$ lies in an open hemisphere in $S(G)$ [6].

3. By going down to a subgroup of finite index if necessary we can assume that $G$ is nilpotent-by-abelian of type $\text{FP}_\infty$, with normal nilpotent subgroup $N$ and abelian quotient $Q = G/N$ such that $N$ and $Q$ are $F$-invariant. By going down to a subgroup of finite index again we can further assume that $Q$ is torsion-free and $Q = C_0 \times T_0$, where $F$ acts trivially on $C_0$ and $e = \sum_{t \in F} t$ acts as zero on $T_0$.

4. Let $A$ be the abelianization of $N$, so the action of $F$ on $N$ induces an action of $Q$ on $A$. Under the assumptions of step 3 since $\text{dis} \Sigma_\chi(Q)$ is contained in some open hemisphere of $S(Q)$ then $A$ is finitely generated as $\mathbb{Z}Q_0$-module (via the conjugation action of $C_0$) and $\text{dis} \Sigma_\chi(C_0)$ is contained in some open hemisphere of $S(C_0)$.

5. Let $C$ be a subgroup of $G$ containing $N$ such that $C_{G/N}(F) = C/N$. Then $C$ is of type $\text{FP}_\infty$.

6. The group $NC_G(F)$ has finite index in $C$. In particular $NC_G(F)$ is of type $\text{FP}_\infty$. 

7. Let $S$ be a subgroup of $G$ such that $SN = G$. Then $S$ is of type $FP_\infty$. Applying this for $NC_G(F)$ in the place of $G$ we deduce that $C_G(F)$ is of type $FP_\infty$.

**Lemma 8.5.** Let $F$ be a finite group acting on a nilpotent-by-abelian group $G$ of type $FP_\infty$ as described in Step 3 above i.e. $N$ is nilpotent, $Q = G/N$ is torsion-free abelian, $N$ and hence $Q$ are $F$-invariant and $Q = C_0 \times T_0$, where $F$ acts trivially on $C_0$ and $e = \sum_{t \in F} t$ acts as zero on $T_0$. Let $\Gamma$ be a finite index extension of $Q$ that contains $F$ and $\chi : \Gamma \to \mathbb{R}$ be a non-trivial homomorphism such that $\chi(N) = 0$. Let $\tilde{\chi} : Q \to \mathbb{R}$ be the homomorphism induced by $\chi$. Suppose that $[\tilde{\chi}] \notin \text{conv} \Sigma^c_A(Q)$, where $A$ is the abelianization of $N$. Then $[\tilde{\chi}|_{C_0}] \notin \text{conv} \Sigma^c_A(C_0)$.

**Proof.** By construction for $V = Q \otimes_{\mathbb{Z}} \mathbb{Q}$ and the idempotent $\tilde{e} = (\frac{1}{|F|}) \sum_{t \in F} t$ we have

$$V = V(1 - \tilde{e}) \oplus V\tilde{e},$$

where $T_0 \otimes_{\mathbb{Z}} \mathbb{Q} = V(1 - \tilde{e})$ and $C_0 \otimes_{\mathbb{Z}} \mathbb{Q} = V(\tilde{e})$. Then $(T_0 \otimes_{\mathbb{Z}} \mathbb{Q}) \otimes_{QF} \mathbb{Q} = 0$, so the image of $T_0$ in the abelianization of $\Gamma$ is finite, in particular

$$\tilde{\chi}(T_0) = 0. \tag{10}$$

The rest of the proof is similar to the proof of [17] Lemma 3.6. We outline the main steps. First by the last paragraph of the proof of [17] Prop. 3.9 (there $C_0$ was denoted by $C$) $A$ is finitely generated as $\mathbb{Z}C_0$-module. Suppose that

$$\tilde{\chi}|_{C_0} = \chi_1 + \ldots + \chi_m,$$

where $[\chi_i] \in \Sigma^c_A(C_0)$. By the link between $\Sigma^c$ and valuations [2 Thm. 8.1] there is $[v_i] \in \Sigma_A^c(Q)$ such that the restriction of $v_i$ to $C_0$ is $\chi_i$, i.e. $v_i = (\chi_i, w_i)$, where $w_i$ is the restriction of $v_i$ on $T_0$. Then

$$\sum_{i \in F} v_i = \sum_{i \in F} (\chi_i, w_i) = (\sum_{i \in F} \chi_i, \sum_{i \in F} w_i) = (\sum_{i \in F} \chi_i, 0).$$

Hence

$$|F|\tilde{\chi} = |F|(\tilde{\chi}|_{C_0}, \tilde{\chi}|_{T_0} = 0) = \sum_{i \in F, 1 \leq i \leq m} v_i,$$

thus $[\tilde{\chi}] \in \text{conv} \Sigma_A^c(Q)$, a contradiction.

\[ \square \]

**Lemma 8.6.** Let $F$ be a finite group acting on a group $G$. Assume that $G$ has a normal $F$-invariant nilpotent subgroup $N$, $Q = G/N$ is torsion-free abelian and $Q = C_0 \times T_0$, where $F$ acts trivially on $C_0$ and $e = \sum_{t \in F} t$ acts as zero on $T_0$. Let $\Gamma$ be a finite extension of $G$ that contains $F$ and $\chi : \Gamma \to \mathbb{R}$ be a non-trivial homomorphism such that $\chi(N) = 0$. Let $C$ be the subgroup of $G$ containing $N$ and such that $C/N = C_{G/N}(F)$. Then $[\chi|_C] \in \Sigma^\infty(C, \mathbb{Z})$. 

Let $C$ be the subgroup of $G$ containing $N$ and such that $C/N = C_{G/N}(F)$. Then $[\chi|_C] \in \Sigma^\infty(C, \mathbb{Z})$. 

abelian. Let 

\[ [\mu](G) \in \Sigma^\infty(G, \mathbb{Z}) = S(G) \setminus (\text{conv} \Sigma^1(G, \mathbb{Z}))^c, \]

Since \( N \) is nilpotent by [18] Thm. 2.3

(11)

\[ \Sigma^1(G, \mathbb{Z})^c = \Sigma_A^c(Q), \]

where \( A \) is the abelianization of \( N \) i.e. for a real homomorphism \( \mu : G \to \mathbb{R} \) we have \( \mu \in \Sigma^1(G, \mathbb{Z})^c \) if and only if \( \mu(N) = 0 \) and for the homomorphism \( \bar{\mu} : Q \to \mathbb{R} \) induced by \( \mu \) we have \( \bar{\mu} \in \Sigma_A^c(Q) = S(Q) \setminus \Sigma_A(Q) \). Hence for the character \( \tilde{\chi} : Q \to \mathbb{R} \) induced by \( \chi \) we have

\[ [\tilde{\chi}] \notin \text{conv} \Sigma_A^c(Q). \]

Then by Lemma 8.5

(12)

\[ [\tilde{\chi}|_{C_0}] \notin \text{conv} \Sigma_A^c(C_0). \]

Since \( C_0 = C/N \), as in (11) we have \( \Sigma_A^c(C_0) = \Sigma^1(C, \mathbb{Z})^c \) and by Theorem 8.1 and (12) we obtain

\[ [\chi|_c] \notin \text{conv} \Sigma^1(C, \mathbb{Z})^c, \]

so \( [\chi|_c] \in \Sigma^\infty(C, \mathbb{Z}) \).

Lemma 8.7. Let \( G \) be a group with a normal nilpotent subgroup \( N \) and \( Q = G/N \) abelian. Let \( \chi : G \to \mathbb{R} \) be a non-trivial character such that \( [\chi] \in \Sigma^\infty(G, \mathbb{Z}) \) and \( \chi(N) = 0 \). Let \( S \) be a subgroup of \( G \) such that \( SN = G \). Then

\[ [\chi|_S] \in \Sigma^\infty(S, \mathbb{Z}). \]

Proof. Since \( \Sigma^\infty(G, \mathbb{Z}) \neq \emptyset, G \) is of type \( FP_\infty \). By [17] Lemma 3.12 \( S \) is of type \( FP_\infty \) and by Theorem 8.1

\[ \Sigma^\infty(S, \mathbb{Z})^c = \text{conv} \Sigma^1(S, \mathbb{Z})^c. \]

Recall that as in (11)

\[ \Sigma^1(S, \mathbb{Z})^c = \Sigma_B^c(Q), \]

where \( B = S \cap N/[S \cap N, S \cap N] \) and \( Q = G/N \simeq S/S \cap N \). Hence to prove the lemma we have to show for the character \( \tilde{\chi} : Q \to \mathbb{R} \) induced by \( \chi|_S \) that

(13)

\[ [\tilde{\chi}] \notin \text{conv} \Sigma_B^c(Q). \]

Note that \( S \) and \( G \) are of type \( FP_\infty, \) so \( \Sigma_B^c(Q) \) and \( \Sigma_A^c(Q) \) contain only discrete points, where \( A = N/[N, N] \). As in the proof of [17] Lemma 3.12

\[ \Sigma_B^c(Q) = \text{dis} \Sigma_B^c(Q) \subseteq \text{conv} \text{dis} \Sigma_A^c(Q) = \text{conv} \Sigma_A^c(Q), \]

hence

(14)

\[ \text{conv} \Sigma_B^c(Q) \subseteq \text{conv} \Sigma_A^c(Q). \]

Using again Theorem 8.1

\[ [\chi] \notin \Sigma^\infty(G, \mathbb{Z})^c = \text{conv} \Sigma^1(G, \mathbb{Z})^c \]

and as in (11)

\[ \Sigma^1(G, \mathbb{Z})^c = \Sigma_A^c(Q). \]

Since \( \chi(N) = 0, \) for \( \tilde{\chi} \) the character induced by \( \chi, \) we have

\[ [\tilde{\chi}] \notin \text{conv} \Sigma_A^c(Q). \]
Then by (14) we deduce that (13) holds. □

We finish the section by proving the following $\Sigma$-version of Theorem 8.4.

**Theorem 8.8.** Let $\Gamma$ be a virtually soluble group of type $\text{FP}_\infty$. Then

$$\Sigma^m(\Gamma, \mathbb{Z}) = \Sigma^m(\Gamma, \mathbb{Z}).$$

**Proof.** Note that by Theorem 8.3 $\Gamma$ has finitely many conjugacy classes of finite subgroups. Observe that by Remark 6.5 we have

$$\Sigma^m(\Gamma, \mathbb{Z}) \subseteq \Sigma^m(\Gamma, \mathbb{Z}).$$

For the converse let $\chi: \Gamma \rightarrow \mathbb{R}$ be a non-zero homomorphism such that $[\chi] \in \Sigma^m(\Gamma, \mathbb{Z})$ and $K$ be a finite subgroup of $\Gamma$. Let $G$ be a normal nilpotent-by-abelian subgroup of $\Gamma$. Then $K$ acts on $G$ via conjugation and $C_G(K)$ has finite index in $C_\Gamma(K)$. By substituting $G$ with a subgroup of finite index if necessary we can assume that the assumptions of Step 3 hold and $\chi(N) = 0$. Then the previous two lemmas imply that $[\chi]|_S \in \Sigma^m(S, \mathbb{Z})$ for $S = C_G(K)$. Since $S$ has finite index in $D = C_\Gamma(K)$ by Theorem 8.2 $[\chi]|_D \in \Sigma^m(D, \mathbb{Z})$.

By the line above (10) and the fact that $C_G(F)N$ has finite index in the preimage of $C_\Gamma$ in $G$ we deduce that $C_\Gamma(F)[\Gamma, \Gamma]$ has finite index in $\Gamma$, hence we can define

$$\tilde{G} := \cap \{C_\Gamma(F)[\Gamma, \Gamma] \mid F \text{ rep. of the conjugacy classes of finite subgroups in } \Gamma \}.$$

Then by Lemma 3.3 and Lemma 3.4 the first condition of Theorem 6.6 holds.

Finally the proof is completed by Theorem 6.6, where condition 2 is substituted with condition 2b). □
