ON A CONJECTURE OF WIDOM

ALEXEI BORODIN AND ALEXEI NOVIKOV

August 25, 2005

ABSTRACT. We prove a conjecture of H. Widom stated in [W] about the reality of eigenvalues of certain infinite matrices arising in asymptotic analysis of large Toeplitz determinants. As a byproduct we obtain a new proof of A. Okounkov’s formula for the correlation functions of the Schur measures on partitions.

INTRODUCTION

The main goal of this note is to prove that the spectrum of the operator $T$ in $L^2(n, n + 1, \ldots), n = 0, 1, \ldots$, with matrix elements

$$T_{pq} = \sum_{k \geq 1} \begin{pmatrix} \phi_- \\ \phi_+ \end{pmatrix}_{p+k} \begin{pmatrix} \phi_+ \\ -\phi_- \end{pmatrix}_{q-k},$$

where $(f)_k$ denotes the $k$th Fourier coefficient of the function $f(z)$ on the unit circle $\{z \in \mathbb{C} : |z| = 1\}$ and

$$\phi_+(z) = e^{\gamma z} \prod_{i \geq 1} \frac{1 + \beta^+_i z}{1 - \alpha^+_i z}, \quad \phi_-(z) = e^{-\gamma /z} \prod_{i \geq 1} \frac{1 + \beta^-_i /z}{1 - \alpha^-_i /z}$$

for certain nonnegative parameters $\{\alpha^+_i\}, \{\beta^+_i\}$ and $\gamma^\pm$ such that $\sum_i (\alpha^+_i + \beta^+_i) < \infty$ and $\alpha^+_i, \beta^+_i \leq \text{const} < 1$ for all $i \geq 1$, is real and lies between 0 and 1.

This property of the operator $T$ turns out to be useful in the asymptotic analysis of growing Toeplitz determinants with symbol $\phi = \phi_+ \phi_-$ or, more generally, of the distribution functions of the largest parts of random partitions distributed according to the associated Schur measure. The statement was conjectured by H. Widom in [W] in the case when the parameters $\alpha^+_i, \beta^-_i, \gamma^- \gamma^+$ vanish and the number of nonzero $\alpha^-_i$’s and $\beta^+_i$’s is finite. Some more special cases were proved in [BDR], [W]. We refer to [W] for details and further references.

The key fact which allows us to prove the reality of spectrum is that the resolvent $T(1 - T)^{-1}$ of matrix $T$ after conjugation by a diagonal matrix with plus-minus ones becomes totally positive. While proving this fact we obtain as a byproduct a new proof of A. Okounkov’s formula for the correlation functions of the Schur measures, see [O] and also [J], [R] for other proofs. More specifically, we show that the Schur measure may be viewed as an $L$-ensemble and explicitly compute the correlation kernel $K = L(1 + L)^{-1}$.

One of the authors (A.B.) was partially supported by the NSF grant DMS-0402047.

AN OPERATOR IDENTITY

In what follows $\mathbb{Z}_+$ denotes the set of nonnegative integers and all contour integrals are taken over circles centered at the origin with radii close enough to 1.

Let $\phi_+$ be a holomorphic function in the disc

$$D_r = \{ z \in \mathbb{C} : |z| \leq r \}$$

with radius $r > 1$, and let $\phi_-$ be a holomorphic function outside the disc $D_{1/r}$. In other words,

$$\phi_+(z) = \sum_{n=0}^{\infty} (\phi_{\pm})_n z^n, \quad (\phi_{\pm})_n = O(r^{-n}) \quad \text{as} \quad n \to \infty.$$ 

Assume also that $\phi_+ \text{ and } \phi_- \text{ do not vanish on } D_r \text{ and } \overline{\mathbb{C}} \setminus D_{1/r}, \text{ respectively.}$

Consider an operator $L$ in $L^2(\mathbb{Z}_+) \oplus L^2(\mathbb{Z}_+)$ with matrix

$$L = \begin{bmatrix} 0 & A^t \\ -B & 0 \end{bmatrix},$$

where the generating functions of matrix elements of $A$ and $B$ are

$$\sum_{p,q \geq 0} A_{pq} u^p v^q = \frac{1}{u+v} \left( \frac{\phi_+(u)}{\phi_+(v)} - 1 \right), \quad \sum_{p,q \geq 0} B_{pq} u^p v^q = \frac{1}{u+v} \left( \frac{\phi_-(u^{-1})}{\phi_-(v^{-1})} - 1 \right).$$

One can also write the matrix elements in terms of the contour integrals

$$A_{pq} = \frac{1}{(2\pi i)^2} \oint \oint \left( \frac{\phi_+(u)}{\phi_+(v)} - 1 \right) \frac{dudv}{(u+v)u^{p+1}v^{q+1}},$$

$$B_{pq} = \frac{1}{(2\pi i)^2} \oint \oint \left( \frac{\phi_-(u^{-1})}{\phi_-(v^{-1})} - 1 \right) \frac{dudv}{(u+v)u^{p+1}v^{q+1}}.$$ 

These integral representations imply that $|A_{pq}|$ and $|B_{pq}|$ decay faster than $\text{const} \cdot x^{-p-q}$ for any $1 < x < r$ as $p + q \to \infty$. Thus, the sum of absolute values of matrix elements of $L$ is finite, and $L$ is a trace class operator.

Note that the change $\phi_+(z) \leftrightarrow \phi_+^{-1}(-z)$ replaces $A$ by $A^t$, the change $\phi_-(z) \leftrightarrow \phi_-^{-1}(-z)$ replaces $B$ by $B^t$, and the change

$$(\phi_+(u), \phi_-(v)) \leftrightarrow (\phi_-(u^{-1}), \phi_+(v^{-1}))$$

switches $A$ and $B$. Thus, the switch $(A, B) \leftrightarrow (B^t, A^t)$ is achieved by

$$(\phi_+(u), \phi_-(v)) \leftrightarrow (\phi_-^{-1}(u^{-1}), \phi_+^{-1}(v^{-1})).$$

Theorem 1. Assume that the operator $1 + A^t B$ is invertible (equivalently, $1 + BA^t$ is invertible). Then the operator $1 + L$ is invertible, and the matrix of the operator $K = L(1 + L)^{-1} = 1 - (1 + L)^{-1}$ has the form

$$K = \begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix} = \begin{bmatrix} 1 - (1 + A^t B)^{-1} & (1 + A^t B)^{-1} A^t \\ -(1 + BA^t)^{-1} B & 1 - (1 + BA^t)^{-1} \end{bmatrix}.$$
where

\[
(K_{11})_{pq} = \delta_{pq} - \frac{(-1)^{p+q}}{(2\pi i)^2} \oint_{|zw|<1} \oint_{|zw|<1} \frac{\Phi(z, w) \, dz \, dw}{(1 - zw)^{p+1} z^{q+1}},
\]

\[
(K_{12})_{pq} = \frac{(-1)^p}{(2\pi i)^2} \oint_{|zw|<1} \Phi(z, w) \, w^q \, dz \, dw,
\]

\[
(K_{21})_{pq} = \frac{(-1)^{q+1}}{(2\pi i)^2} \oint_{|zw|<1} \Phi(z, w) \, w^p \, dz \, dw,
\]

\[
(K_{22})_{pq} = \frac{1}{(2\pi i)^2} \oint_{|zw|<1} \oint_{|zw|<1} \frac{\Phi(z, w) \, z^p z^q \, dz \, dw}{1 - zw},
\]

and

\[
\Phi(z, w) = \frac{\phi_-(z) \phi_+(w^{-1})}{\phi_+(z) \phi_-(w^{-1})}.
\]

**Proof:** The proof of the first equality is straightforward. Thanks to the symmetries mentioned before the statement of the theorem it suffices to prove the integral formulas for \(K_{11}\) and \(K_{12}\). Let us start with \(K_{11}\).

We need to show that \((1 + A^t B)(1 - K_{11}) = 1\) or, equivalently, \(A^t B(1 - K_{11}) = K_{11}\). Explicit computation gives

\[
(A^t B(1 - K_{11}))_{pq} = \sum_{l, m \geq 0} A_{lp} B_{lm} (1 - K_{11})_{mq}
\]

\[
= \frac{1}{(2\pi i)^6} \oint_{|zw|<1} \oint_{|zw|<1} \sum_{l, m \geq 0} \left( \frac{\phi_+^l(u_1)}{\phi_+^l(-v_1)} - 1 \right) \frac{du_1 \, dv_1}{(u_1 + v_1)^{l+1} v_1^{p+1}} \times \left( \frac{\phi_-^l(u_2^{-1})}{\phi_-^l(-v_2^{-1})} - 1 \right) \frac{du_2 \, dv_2}{(u_2 + v_2)^{l+1} v_2^{m+1}} \frac{\phi_-^l(z) \phi_+^l(w^{-1})}{\phi_+^l(-v_1)} \frac{dz \, dw}{(1 - zw)^{l+1} (-w)^{m+1}}
\]

\[
= \frac{1}{(2\pi i)^6} \oint_{|zw|<1} \oint_{|zw|<1, |u_1| > 1, |v_1| > 1} \sum_{l, m \geq 0} \left( \frac{\phi_+^l(u_1)}{\phi_+^l(-v_1)} - 1 \right) \frac{du_1 \, dv_1}{(u_1 + v_1)^{l+1} v_1^{p+1}} \times \left( \frac{\phi_-^l(u_2^{-1})}{\phi_-^l(-v_2^{-1})} - 1 \right) \frac{du_2 \, dv_2}{(u_2 + v_2)^{l+1} v_2^{m+1}} \frac{\phi_-^l(z) \phi_+^l(w^{-1})}{\phi_+^l(-v_1)} \frac{dz \, dw}{(-w)^{l+1} (u_1 v_1)^{l+1} (v_1 u_2 - 1)(v_2 z + 1)(1 - zw)}
\]

where we imposed additional conditions \(|u_1 u_2| > 1, |v_2| > 1\) on the integration contours to ensure the convergence of two geometric series under the integral.

We can immediately perform the integration over \(u_2\) and \(v_2\). Indeed, there is only one simple pole \(u_2 = u_1^{-1}\) inside the \(u_2\)-contour and there is only one simple pole \(v_2 = -z^{-1}\) inside the \(v_2\)-contour. Evaluating the residues we obtain that the integral above equals

\[
\frac{1}{(2\pi i)^4} \oint_{|zw|<1} \left( \frac{\phi_+^l(u_1)}{\phi_+^l(-v_1)} - 1 \right) \frac{du_1 \, dv_1}{(u_1 + v_1)^{l+1} v_1^{p+1}} \times \left( \frac{\phi_-^l(u_1)}{\phi_-^l(z)} - 1 \right) \frac{1}{(z - u_1)} \frac{\phi_-(z) \phi_+(w^{-1})}{\phi_+(z) \phi_-(w^{-1})} \frac{dz \, dw}{(-w)^{l+1} (1 - zw)} \frac{dz \, dw}{(1 - zw)}.
\]

Let us choose the contours so that \(|u_1| < |z|\) and open the parentheses \(\left( \frac{\phi_-(u_1)}{\phi_-(z)} - 1 \right)\) in the integral above. The second term vanishes because it has no singularities inside
the \( u_1 \)-contour. The first term has only one simple pole \( z = u_1 \) inside the \( z \)-contour, and the integration over \( z \) gives

\[
\frac{1}{(2\pi i)^3} \iint_{|u_1 w| < 1} \left( \frac{\phi_+(u_1)}{\phi_+(v_1)} - 1 \right) \frac{du_1 dv_1}{(u_1 + v_1) v_1^{p+1}} \phi_-(u_1) \phi_+(w^{-1}) dw \frac{(-1)}{\phi_+(u_1) \phi_-(w^{-1})} \frac{dw}{(-w)^q + (1 - u_1 w)}.
\]

Now let us choose the contours so that \( |u_1| > |v_1| \) and open the parentheses \( \phi_+(u_1) - 1 \). The first term can be integrated over \( u_1 \) — there is only one pole \( u_1 = -v_1 \) inside the \( u_1 \)-contour. Thus, the first term equals the corresponding residue, that is

\[
\frac{-1}{(2\pi i)^2} \int_{|v_1 w| < 1} \phi_+(w^{-1}) dw \frac{dv_1}{\phi_+(v_1) (1 + v_1 w) v_1^{p+1} (-w)^q + (1 - u_1 w)}.
\]

By deforming the \( w \)-contour to \( \infty \) and picking up the residue at \( w = -v_1^{-1} \) we immediately see that this integral is equal to \( \delta_{pq} \).

Now the second term is equal to

\[
\frac{1}{(2\pi i)^3} \iint_{|u_1 w| < 1, |u_1| >> |v_1|} \frac{du_1 dv_1}{(u_1 + v_1) v_1^{p+1}} \frac{\phi_-(u_1) \phi_+(v_1) \phi_+(w^{-1})}{\phi_+(u_1) \phi_-(w^{-1})} \frac{dw}{(1 - u_1 w) (-w)^q + (1 - u_1 w)}.
\]

Deforming the \( v_1 \)-contour to \( \infty \) we pick up the residue at \( v_1 = -u_1 \) which gives

\[
\frac{-1}{(2\pi i)^2} \int_{|u_1 w| < 1} \phi_-(u_1) \phi_+(w^{-1}) \frac{du_1}{\phi_+(v_1) \phi_-(w^{-1}) (1 - u_1 w) (-u_1 w)^p + (1 - u_1 w)^q},
\]

and this is exactly \( (K_{11})_{pq} - \delta_{pq} \). The proof of the formula for \( K_{11} \) is complete.

In order to prove the formula for \( K_{12} \) we need to show that \( (1 + A^t B)K_{12} = A^t \) or \( A^t B K_{12} = A^t - K_{12} \). The computation of \( A^t B K_{12} \) literally follows the above arguments for \( K_{11} \) and leads to the sum of two terms:

\[
\frac{1}{(2\pi i)^2} \iint_{|u_1 w| < 1} \phi_+(w^{-1}) w^q dw \frac{dv_1}{\phi_+(v_1) (1 + v_1 w) v_1^{p+1}} + \frac{1}{(2\pi i)^2} \iint_{|u_1 w| < 1} \phi_-(u_1) \phi_+(w^{-1}) \frac{du_1}{\phi_+(u_1) \phi_-(w^{-1})} \frac{dw}{(1 - u_1 w) (-u_1 w)^p + (1 - u_1 w)^q}.
\]

The first term is immediately seen to be equal to \( A_{qp} \) and the second one is exactly \( -(K_{12})_{pq} \). \( \square \)

**Schur functions and Schur measures**

We refer the reader to [M], [S] for general information on partitions and symmetric functions.

Let \( \Lambda \) be the algebra of symmetric functions. It can be viewed as the algebra of polynomials in countably many indeterminates \( \Lambda = \mathbb{C}[h_1, h_2, \ldots] \) where the indeterminates \( h_k \) are the complete homogeneous symmetric functions of degree \( k \). We also agree that \( h_0 = 1 \) and \( h_{-k} = 0 \) for \( k < 0 \).
The Schur symmetric functions $s_\lambda$ are parameterized by partitions $\lambda$ and are expressed through $h_k$'s by the Jacobi-Trudi formula

$$s_\lambda = \det[h_{\lambda_i - i + j}]_{i,j=1}^N$$

where $N$ is any number greater or equal to the number of nonzero parts of $\lambda$. The Schur functions form a linear basis in $\Lambda$.

An algebra homomorphism $\pi : \Lambda \rightarrow \mathbb{C}$ is uniquely determined by its values on $h_k$'s, or by generating series of these values

$$H_\pi(z) = \sum_{n=0}^\infty \pi(h_n) z^n.$$ 

Recall that a sequence $\{a_n\}_{n=0}^\infty$ is called \textit{totally positive} if all minors of the matrix $[a_i - j]_{i,j \geq 0}$ are nonnegative. Here all $a_i \gamma$ for $k > 0$ are assumed to be equal to zero.

We will only consider totally positive sequences with $a_0 = 1$; clearly, multiplication of all members of a sequence by the same positive number does not affect total positivity.

The following statement was independently proved by Aissen-Edrei-Schoenberg-Whitney in 1951 [AESW], [E], and by Thoma in 1964 [T]. An excellent exposition of deep relations of this result to representation theory of the infinite symmetric group can be found in Kerov’s book [K].

\textbf{Theorem 2.} A sequence $\{a_n\}_{n=0}^\infty$, $a_0 = 1$, is totally positive if and only if its generating series has the form

$$\sum_{n=0}^\infty a_n z^n = e^{\gamma z} \prod_{i \geq 1} \frac{1 + \beta_i z}{1 - \alpha_i z} =: F(\alpha, \beta, \gamma)$$

for certain nonnegative parameters $\{\alpha_i\}$, $\{\beta_i\}$ and $\gamma$ such that $\sum_i (\alpha_i + \beta_i) < \infty$.

Equivalently, an algebra homomorphism $\pi : \Lambda \rightarrow \mathbb{C}$ takes nonnegative values on all Schur functions if and only if the sequence $\{\pi(h_n)\}_{n \geq 0}$ is totally positive, that is, $H_\pi(z) = F(\alpha, \beta, \gamma)$ for a suitable choice of parameters $(\alpha, \beta, \gamma)$.

We will call a specialization $\pi : \Lambda \rightarrow \mathbb{C}$ \textit{positive} if $\pi(s_\lambda) \geq 0$ for all partitions $\lambda$. Thus, the theorem above may be viewed as a classification of all positive specializations of the algebra of symmetric functions.

Let us now consider specializations $\pi_+$ and $\pi_-$ of $\Lambda$ such that

$$H_{\pi_+}(z) = \phi_+(z), \quad H_{\pi_-}(z) = \phi_-(z^{-1})$$

for the holomorphic functions $\phi^\pm$ of the previous section, and set $s_\lambda^\pm := \pi_\pm(s_\lambda)$.

Following A. Okounkov [O] assign to any partition $\lambda$ the following (generally speaking, complex) weight

$$P\{\lambda\} = \frac{s_\lambda^+ s_\lambda^-}{Z}, \quad Z = \exp \sum_{k \geq 1} k \ln \phi_+(z) \ln \phi_-(z)^k.$$

One can show that $\sum_\lambda P\{\lambda\}$ is an absolutely convergent series with sum equal to 1. The distribution $P$ is called the \textit{Schur measure}.

Theorem 1 proved in the previous section yields a new proof of the determinantal formula for the correlation functions of the Schur measure.

The following statement was proved in [O]; other proofs can be found in [J], [R].

For any partition $\lambda$ denote by $L(\lambda)$ the infinite subset $\{\lambda_i - i\}_{i=1}^\infty$ of $\mathbb{Z}$. 

Theorem 3. For any \( x_1, \ldots, x_n \in \mathbb{Z} \)

\[
\sum_{\lambda : \mathcal{L}(\lambda) \supset \{x_1, \ldots, x_n\}} P(\lambda) = \det[\mathcal{K}(x_i, x_j)]_{i,j=1}^n
\]

where

\[
\mathcal{K}(x, y) = \frac{1}{(2\pi i)^2} \oint_{|z|<1} \oint \frac{\phi_-(z)\phi_+(w^{-1})}{\phi_+(z)\phi_-(w^{-1})} \frac{z^p w^q dz dw}{1 - zw}.
\]

Proof. We will use the material of Appendix in [BOO]. Let \( \lambda \) be a partition and \((p_1, \ldots, p_d \mid q_1, \ldots, q_d)\) be its Frobenius coordinates. Using the well-known Giambelli formula \( s_\lambda = \det[s(p_i\mid q_j)]_{i,j=1}^d \), see e.g. [M, Ex. I.3.9], we obtain

\[
P(\lambda) = \frac{s^+_{(p_i\mid q_j)}^\lambda s^-_{(p_i\mid q_j)}^\lambda}{Z} = Z^{-1} \prod_{i,j=1}^d \det[s_{(p_i\mid q_j)}^\lambda].
\]

Comparing the following formula for the generating series of the hook Schur functions

\[
1 + (u + v) \sum_{p,q \geq 0} s(p\mid q) u^p v^q = \frac{H(u)}{H(-v)}, \quad H(z) = \sum_{n=0}^\infty h_n z^n,
\]

see e.g. [M, Ex. I.3.14], with the definition of matrices \( A \) and \( B \) in the previous section we see that

\[
s^+(p\mid q) = A_{pq}, \quad s^-(p\mid q) = B_{pq}, \quad p, q \geq 0.
\]

Thus,

\[
P(\lambda) = Z^{-1} \cdot \det[A_{(p_i\mid q_j)}]_{i,j=1}^d \det[B_{(p_i\mid q_j)}]_{i,j=1}^d
\]

is, up to a constant, the value of the symmetric minor of the matrix \( L \) from the previous section with \( 2d \) rows and \( 2d \) columns marked by \((q_1, \ldots, q_d \mid p_1, \ldots, p_d)\). This means that the Schur measure interpreted through the Frobenius coordinates of partitions defines a determinantal point process on \( \mathbb{Z}_+ \sqcup \mathbb{Z}_+ \), and its correlation kernel is given by \( K = L(1 + L)^{-1} \). (The operator \( 1 + L \) is invertible because \( \det(1 + L) = Z \neq 0 \).

Finally, to pass from Frobenius coordinates \((p_1, \ldots, p_d \mid q_1, \ldots, q_d) \subset \mathbb{Z}_+ \sqcup \mathbb{Z}_+\) to \( \mathcal{L}(\lambda) \subset \mathbb{Z} \) we can use the complementation principle, see [§A.3, BOO], thanks to the Frobenius lemma

\[
\mathcal{L}(\lambda) = \{p_1, \ldots, p_d\} \sqcup \{-1, -2, -3, \ldots\} \setminus \{-q_1 - 1, \ldots, -q_d - 1\},
\]

see e.g. [M, I.1(1.7)]. It is readily seen that the operation \( \Delta \) of [§A.3, BOO] transforms the kernel \( K \) of Theorem 1 to the kernel \( K \) of Theorem 3 up to a conjugation by a diagonal matrix of plus-minus 1’s. Since such conjugation does not change the determinants \( \det[\mathcal{K}(x_i, x_j)]_{i,j=1}^n \), the proof is complete. \( \square \)
Total positivity and Widom’s conjecture

In this section we assume that the functions $\phi_+(z)$ and $\phi_-(z^{-1})$ are generating functions of totally positive sequences, that is,

$$
\phi_+(z) = e^{\gamma^+ \sum_{i \geq 1} (1 + \beta_i^+ z) / \prod_{i \geq 1} (1 - \alpha_i^+ z)}, \quad \phi_-(z) = e^{\gamma^- / \sum_{i \geq 1} (1 + \beta_i^- z) / \prod_{i \geq 1} (1 - \alpha_i^- z)}
$$

for certain nonnegative parameters $\{\alpha_i^\pm\}, \{\beta_i^\pm\}$ and $\gamma^\pm$ such that $\sum_i (\alpha_i^\pm + \beta_i^\pm) < \infty$ and $\alpha_i^+, \beta_i^+ < r^{-1} < 1$ for all $i \geq 1$.

Let $P_n$ be the projection operator in $L^2(\mathbb{Z}_+)$ which projects onto $n$ first basis vectors:

$$
P_n : (x_0, x_1, x_2, \ldots) \mapsto (x_0, x_1, \ldots, x_{n-1}, 0, 0, \ldots).
$$

**Theorem 4.** Under the above assumption, for any $n = 1, 2, \ldots$ the spectra of the operators $K_{11}^{(n)} = (1 - P_n)K_{11}(1 - P_n)$ and $K_{22}^{(n)} = (1 - P_n)K_{22}(1 - P_n)$ are real and lie between 0 and 1.

Let us start with a lemma.

**Lemma 5.** Let $T_n$ be a sequence of trace class operators in a Hilbert space which converges to a (trace class) operator $T$ in trace norm. Assume that $\text{Sp}(T_n) \subset S$ for a closed set $S \subset \mathbb{C}$ and all large enough $n$. Then $\text{Sp}(T) \subset S \cup \{0\}$.

**Proof.** By virtue of [Proposition A.11, BOO], trace norm convergence implies the convergence of entire functions in $z$

$$
det(1 + zT_n) \to det(1 + zT)
$$

uniformly on compact subsets of $\mathbb{C}$. Therefore, any zero of $\text{det}(1 + zT)$ is a limit point of zeroes of $\text{det}(1 + zK_n)$. □

**Proof of Theorem 4.** Let us first show that $\text{Sp}(K_{11})$ and $\text{Sp}(K_{22})$ lie inside the interval $[0, 1]$.

Since the specializations $\pi_\pm$ associated with $\phi_\pm$ are positive, the matrices $A$ and $B$ are totally positive. Indeed, by Giambelli’s formula their minors are values of $\pi_\pm$ on appropriate Schur functions. Furthermore, recall that $A_{pq}$ and $B_{pq}$ decay faster than const $x^{-p-q}$ for any $1 < x < r$ as $p + q \to \infty$. This means that the matrix $A'B$ is also totally positive and its matrix elements satisfy similar estimates. Consequently, $A'B$ is a trace class operator, and $\text{det}(1 + A'B) - 1$ is equal to the sum of all symmetric minors of $A'B$, which is nonnegative. Thus, the operator $1 + A'B$ is invertible.

The decay of the matrix elements of $A'B$ shows that $P_nA'BP_n$ converges to $A'B$ in trace norm as $n \to \infty$ (indeed, the trace norm of a matrix does not exceed the sum of the absolute values of the matrix elements). It is well known that the eigenvalues of a totally positive matrix are nonnegative, see e.g. [An, Corollary 6.6]. Hence, $\text{Sp}(P_nA'BP_n) \subset \mathbb{R}_{\geq 0}$, and by Lemma 5, $\text{Sp}(A'B) \subset \mathbb{R}_{\geq 0}$. Therefore, $\text{Sp}(K_{11}) = A'B(1 + A'B)^{-1} \subset [0, 1)$. The argument for $K_{22}$ is very similar.

To extend the argument to $K_{11}^{(n)}, K_{22}^{(n)}$ we need a linear algebraic lemma.
Lemma 6. Let $C$ be a $(m+n) \times (m+n)$ matrix such that $1+C$ is invertible, and let $D$ be the $n \times n$ lower right corner of $C(1+C)^{-1}$. Then

$$\det(1-D) = \sum_{X \subset \{1, \ldots, m\}} \frac{C(X)}{\det(1+C)}$$

(the sum above includes $X = \emptyset$ and $C(\emptyset) = 1$). Assume further that $\det(1-D) \neq 0$ and set $E = D(1-D)^{-1}$. Then any minor of $E$ is, up to a constant, a sum of certain minors of the initial matrix $C$:

$$\frac{E(X)}{\det(1+E)} = \sum_{Z \subset \{1, \ldots, m\}} \frac{C(Z \cup X)}{\det(1+C)} \frac{C(Z \cup Y)}{\det(1+C)}.$$

The proof is straightforward.

Now we can apply this statement to the totally positive matrices $C = P_mA^tBP_m$, $m > n$. Then, clearly, $\det(1-D) > 0$, and $E = D(1-D)^{-1}$ is totally positive. Since eigenvalues of totally positive matrices are nonnegative, we obtain $Sp(D) \subset [0, 1)$. As was mentioned earlier, $P_mA^tBP_m \to A^tB$ in trace norm as $m \to \infty$. Hence, $D \to K_{11}^{(n)}$ in trace norm as $m \to \infty$, and Lemma 5 implies that $Sp(K_{11}^{(n)}) \subset [0, 1]$. The case of $K_{22}^{(n)}$ is handled similarly. □

Note now that by expanding $(1-zw)^{-1} = 1 + zw + (zw)^2 + \ldots$ in the integral representation for $K_{11}$ we obtain

$$(K_{11})_{pq} = \delta_{pq} - (-1)^{p+q} \sum_{k \geq 1} \frac{\phi_-}{\phi_+} \frac{\phi_+}{\phi_-}^{p-k} \frac{\phi_+}{\phi_-}^{-q+k} = (-1)^{p+q} \sum_{k \geq 1} \frac{\phi_-}{\phi_+}^{p+k} \frac{\phi_+}{\phi_-}^{-q-k}.$$

H. Widom in [W] conjectured that the eigenvalues of the operator in $L^2(n, n + 1, \ldots)$ with $(p, q)$-matrix element

$$\sum_{k \geq 1} \frac{\phi_+}{\phi_+}^{p+k} \frac{\phi_+}{\phi_-}^{-q-k}$$

lie between 0 and 1 for the specific choice of

$$\phi_+(z) = \prod_{i \geq 1} (1 + r_i z), \quad \phi_-(z) = \prod_{i \geq 1} (1 - s_i z^{-1})^{-1}$$

with nonnegative $r_i$ and $s_i$ only finitely many of which are nonzero; $r_i, s_i < 1$. Clearly, this statement is an immediate corollary of Theorem 4.
