Fourier and Circulant Matrices are Not Rigid

Zeev Dvir∗ Allen Liu†

Abstract

The concept of matrix rigidity was first introduced by Valiant in [Val77]. Roughly speaking, a matrix is rigid if its rank cannot be reduced significantly by changing a small number of entries. There has been extensive interest in rigid matrices as Valiant showed in [Val77] that rigidity can be used to prove arithmetic circuit lower bounds.

In a surprising result, Alman and Williams showed that the (real valued) Hadamard matrix, which was conjectured to be rigid, is actually not very rigid. This line of work was extended by [DE17] to a family of matrices related to the Hadamard matrix, but over finite fields. In our work, we take another step in this direction and show that for any abelian group $G$ and function $f: G \to \mathbb{C}$, the matrix given by $M_{xy} = f(x - y)$ for $x, y \in G$ is not rigid. In particular, we get that complex valued Fourier matrices, circulant matrices, and Toeplitz matrices are all not rigid and cannot be used to carry out Valiant’s approach to proving circuit lower bounds. This complements a recent result of Goldreich and Tal [GT16] who showed that Toeplitz matrices are nontrivially rigid (but not enough for Valiant’s method). Our work differs from previous non-rigidity results in that those works considered matrices whose underlying group of symmetries was of the form $\mathbb{F}_n^p$ with $p$ fixed and $n$ tending to infinity, while in the families of matrices we study, the underlying group of symmetries can be any abelian group and, in particular, the cyclic group $\mathbb{Z}_N$, which has very different structure. Our results also suggest natural new candidates for rigidity in the form of matrices whose symmetry groups are highly non-abelian.

Our proof has four parts. The first extends the results of [AW16, DE17] to generalized Hadamard matrices over the complex numbers via a new proof technique. The second part handles the $N \times N$ Fourier matrix when $N$ has a particularly nice factorization that allows us to embed smaller copies of (generalized) Hadamard matrices inside of it. The third part uses results from number theory to bootstrap the non-rigidity for these special values of $N$ and extend to all sufficiently large $N$. The fourth and final part involves using the non-rigidity of the Fourier matrix to show that the group algebra matrix, given by $M_{xy} = f(x - y)$ for $x, y \in G$, is not rigid for any function $f$ and abelian group $G$.

1 Introduction

1.1 Background

A major goal in complexity theory is to prove lower bounds on the size and depth of arithmetic circuits that compute certain functions. One specific problem that remains open despite decades of effort is to find functions for which we can show super-linear size lower bounds for circuits of logarithmic depth. In [Val77], Valiant introduced the notion of matrix rigidity as a possible method of proving such lower bounds for arithmetic circuits. More precisely, over a field $\mathbb{F}$, an $m \times n$ matrix $M$ is said to be $(r, s)$-rigid if any $m \times n$ matrix of rank at most $r$ differs from $M$ in at least $s$ entries. Valiant showed that for any linear function $f: \mathbb{F}^n \to \mathbb{F}^n$ that can be computed by an arithmetic circuit of size $O(n)$ and depth $O(\log n)$, the corresponding matrix can be reduced to rank $O\left(\frac{n}{\log \log n}\right)$ by changing $O(n^{1+\epsilon})$ entries for any $\epsilon > 0$. Thus, to prove a circuit lower bound for a function $f$, it suffices to lower bound the rigidity of the corresponding matrix at rank $O\left(\frac{n}{\log \log n}\right)$. We call a matrix Valiant-rigid if it is $\left(O\left(\frac{n}{\log \log n}\right), O(n^{1+\epsilon})\right)$-rigid for some $\epsilon > 0$.

i.e. sufficiently rigid for Valiant’s method to yield circuit lower bounds. Over any infinite field, Valiant shows that almost all \( n \times n \) matrices are \( (r, (n - r)^2) \)-rigid for any \( r \), while over a finite field one can get a similar result with a logarithmic loss in the sparsity parameter. Despite extensive work, explicit constructions of rigid matrices have remained elusive.

Over infinite (or very large) fields, there are ways to construct highly rigid matrices using either algebraically independent entries or entries that have exponentially large description (see [Lok06, KLP14, Lok00]). However, these constructions are not considered to be fully explicit as they do not tell us anything about the computational complexity of the corresponding function. Ideally, we would be able to construct rigid \( 0,1 \)-matrices, but even a construction where the entries are in a reasonably simple field (such as the Fourier matrix) would be a major breakthrough. The best known constructions of such matrices are \( (r, O(\frac{n}{\log n}) \)-rigid (see [SSS97, Fri93]). There has also been work towards constructing semi-explicit rigid matrices, which require \( O(n) \) bits of randomness (instead of the usual \( O(n^2) \)), as such a construction would still yield circuit lower bounds through Valiant’s approach. The best result in this realm (see [GT16]) shows that random Toeplitz matrices are \( (r, \frac{n^3}{r \log n}) \)-rigid with high probability. Note that both of these bounds become trivial when \( r \) is \( \frac{n}{\log \log n} \).

Many well-known families of matrices, such as Hadamard matrices and Fourier transform matrices, have been conjectured to be Valiant-rigid [ALT09]. However, a recent line of works (see [AW16, DE17]) shows that certain well-structured matrices are not rigid. Alman and Williams show in [AW16] that the \( 2^n \times 2^n \) Hadamard matrix, given by \( H_{x,y} = (-1)^{x \cdot y} \) as \( x \) and \( y \) range over \( \{0,1\}^n \), is not Valiant-rigid over \( \mathbb{Q} \). Along similar lines, Dvir and Edelman show in [DE17] that group algebra matrices for the additive group \( \mathbb{F}_p^n \), given by \( M_{x,y} = f(x-y) \) where \( f: \mathbb{F}_p^n \to \mathbb{F}_p \) and \( x, y \) range over \( \mathbb{F}_p^n \), are not Valiant-rigid over \( \mathbb{F}_p \) (where we view \( p \) as fixed and \( n \) goes to infinity). The Hadamard matrix and the group algebra matrices for \( \mathbb{F}_p^n \) satisfy the property that for any \( \epsilon > 0 \), there exists an \( \epsilon' > 0 \) such that it is possible to change at most \( N^{1+\epsilon'} \) entries and reduce the rank to \( N^{1-\epsilon'} \) (where \( N \) denotes the size of the matrix). The proofs of both results rely on constructing a matrix determined by a polynomial \( P(x, y) \) that agrees with the given matrix on almost all entries and then arguing that the constructed matrix has low rank.

1.2 Our Contribution

In this paper, we show that several broad families of matrices, including Fourier, circulant and Toeplitz matrices, are all not Valiant-rigid. The families of matrices we consider in our work have very different underlying group structure than those considered in previous works. Both [AW16, DE17] analyze matrices constructed from an underlying group of the form \( \mathbb{F}_p^n \) with \( p \) fixed and \( n \) tending to infinity. Fourier and circulant matrices, which we focus on, are analogs of the Hadamard and group algebra matrices for a cyclic group \( \mathbb{Z}_N \). Since any abelian group can be decomposed into simple building blocks of the form \( \mathbb{Z}_N \), our results extend to all abelian groups (see details below). While most natural constructions of matrices are highly symmetric, our results suggest that matrices that are symmetric under abelian groups are not rigid and that perhaps we should look toward less structured matrices, or matrices whose symmetry group is non-abelian, as candidates for rigidity.

We now move into a more technical overview of our paper. Define the regular-rigidity of a matrix \( A \), \( r_A(r) \), as the minimum value of \( s \) such that it is possible to change at most \( s \) entries in each row and column of \( A \) to obtain a matrix of rank at most \( r \). The notion of regular-rigidity is weaker than the usual notion of rigidity (and is also weaker than the commonly used notion of row-rigidity) as if \( A \) is an \( n \times n \) matrix and

\[ r_A(r) = \frac{n}{\log \log n} \]

1It remains open to construct a matrix that is Valiant-rigid, even if we only require that the entries live in a number field of dimension polynomial in the size of the matrix.

2Note however, that it is easy to construct rigid matrices with \( O(n^{1+\epsilon}) \) bits of randomness for any \( \epsilon > 0 \) (for example by taking a random matrix with at most \( n^\epsilon \) non-zeros per row) but this is not sufficient for Valiant’s approach.

3It is not hard to see that rigidity of circulant and Toeplitz matrices is essentially the same question so for the sake of consistency with our (group theoretic) approach we will primarily consider circulant matrices.

4While group algebra matrices are supposed to be defined as \( M_{x,y} = f(x - y) \), we will work with \( M_{x,y} = f(x + y) \) in the body of our paper for technical reasons. Note that the two definitions differ only in a permutation of the rows and thus have the same rigidity.
A is \((r, ns)\)-rigid then \(r_A(r) \geq s\). Note that this actually makes our results stronger as we will show that the matrices we consider are not regular-rigid.

All matrices that we deal with will be over \(\mathbb{C}\). The \(d^n \times d^n\) generalized Hadamard matrix \(H_{d,n}\) has rows and columns indexed by \(\mathbb{Z}_d^n\) and entries \(H_{xy} = \omega^{xy}\) where \(\omega = e^{2\pi i / d}\). Throughout this paper, we use the term Hadamard matrix to refer to any generalized Hadamard matrix. We use \(F_N\) to denote the \(N \times N\) Fourier transform matrix. Our main result, that all Fourier matrices are not rigid enough to carry out Valiant’s approach, is stated below.

**Theorem 1.1** (Fourier Matrices are Not Rigid). Let \(F_N\) denote the \(N \times N\) Fourier transform matrix. For any fixed \(0 < \epsilon < 0.1\) and \(N\) sufficiently large,

\[
r_{F_N} \left( \frac{N}{2^{\epsilon(1 - (\log N)^{10^{-9}})}} \right) \leq N^{20\epsilon}
\]

One key idea in our work is the observation that, if a large family of matrices \(A\) are all diagonalizable by a single matrix \(M\) then, the rigidity of any matrix \(A \in A\) implies the rigidity of the single matrix \(M\). This situation happens, e.g., when \(A\) is the family of circulant matrices and \(M\) is the Fourier matrix. This simple, yet crucial observation allows us to deduce the non-rigidity of a larger family of matrices.

**Corollary 1.2.** [Circulant Matrices are not Rigid] Let \(0 < \epsilon < 0.1\) be fixed. For all sufficiently large \(N\), if \(M\) is an \(N \times N\) circulant matrix over \(\mathbb{C}\),

\[
r_M \left( \frac{N}{2^{\epsilon(1 - (\log N)^{10^{-9}})}} \right) \leq N^{20\epsilon}
\]

Also notice that since any Toeplitz matrix of size at most \(N^2\) can be embedded in an \(N \times N\) circulant matrix, the above implies an analogous result for all Toeplitz matrices. While [GT16] shows nontrivial rigidity lower bounds for rank much smaller than \(N\), our results imply that there are actually no nontrivial rigidity lower bounds for rank close to \(N\).

With a bit more work, it is possible to prove the non-rigidity of group algebra matrices for any abelian group.

**Theorem 1.3.** Let \(0 < \epsilon < 0.1\) be fixed. Let \(G\) be an abelian group and \(f : G \rightarrow \mathbb{C}\) be a function. Let \(M\) be a matrix with rows and columns indexed by elements \(x, y \in G\) and entries \(M_{xy} = f(x - y)\). If \(|G|\) is sufficiently large then

\[
r_M \left( \frac{2|G|}{2^{\epsilon(1 - (\log |G|)^{10^{-9}})}} \right) \leq |G|^{26\epsilon}
\]

### 1.3 Proof Overview

We now take a more detailed look at the techniques used in the proof of Theorem 1.1.

#### 1.3.1 Generalized Hadamard Matrices

The first step in the proof of Theorem 1.1 is proving the following result that all Hadamard matrices are not rigid.

**Theorem 1.4** (Hadamard Matrices are not Rigid). For fixed \(d\) and \(0 < \epsilon < 0.1\), there exists an \(\epsilon'\) such that for all sufficiently large \(n\),

\[
r_{H_{d,n}} \left( d^{n(1 - \epsilon')} \right) \leq d^{n\epsilon'}
\]

Note that Theorem 1.4 generalizes the main result of [AW16] (which only deals with \(d = 2\)). Also, given any \(d^n \times d^n\) matrix of the form \(M_{xy} = f(x - y)\) with \(f : \mathbb{Z}_d^n \rightarrow \mathbb{C}\), we can permute its rows so that it is diagonalized by \(H_{d,n}\). Thus, we can apply the diagonalization trick mentioned above and obtain the following result, which extends the work in [DE17] to matrices over \(\mathbb{C}\).

**Corollary 1.5.** Let \(f\) be a function from \(\mathbb{Z}_d^n \rightarrow \mathbb{C}\) and let \(M\) be a \(d^n \times d^n\) matrix with \(M_{xy} = f(x - y)\). Then for any fixed \(d\) and \(0 < \epsilon < 0.1\), there exists an \(\epsilon' > 0\) such that for all sufficiently large \(n\),

\[
r_{M} \left( d^{n(1 - \epsilon')} \right) \leq d^{n\epsilon'}
\]
1.3.2 Fourier Matrices

Equipped with the machinery for Hadamard matrices, we can complete the proof of Theorem 1.6. Our proof consists of two steps. First we show that for integers $N$ of a very special form, the $N \times N$ Fourier matrix is not rigid because it can be decomposed into submatrices with Hadamard-type structure. We say an integer $N$ is well-factorable if it is a product of distinct primes $q_1, \ldots , q_l$ such that for all $i$, $q_i - 1$ has no large prime power divisors. We will make this notion more precise later, but informally, the first step is as follows:

**Theorem 1.6.** Let $F_N$ denote the $N \times N$ Fourier transform matrix. For any fixed $0 < \epsilon < 0.1$ and well-factorable integer $N$, we have

$$r_{F_N} \left( \frac{N}{2^{4\epsilon \log(N)^{1/2}}\min\{q_i\}} \right) \leq N^{4\epsilon}$$

The main intuition is that if $N$ is a product of distinct primes $q_1, \ldots , q_l$, then within the Fourier matrix $F_N$, we can find submatrices whose rows and columns can be indexed by $\mathbb{Z}_{q_1}^* \otimes \cdots \otimes \mathbb{Z}_{q_l}^*$. This multiplicative structure can be replaced by the additive structure of $\mathbb{Z}_{q_1 - 1} \otimes \cdots \otimes \mathbb{Z}_{q_l - 1}$. We can then factor each additive group $\mathbb{Z}_{q_i - 1}$ into prime power components. If $q_1 - 1, \ldots , q_l - 1$ all have no large prime power divisors, we expect prime powers to be repeated many times when all of the terms are factored. This allows us to find submatrices with $\mathbb{Z}_d^l$ additive structure for which we can apply tools such as Theorem 1.4 and Corollary 1.5 to reduce the rank while changing a small number of entries. We then bound the rank and total number of entries changed over all submatrices to deduce that $F_N$ is not rigid.

The second step of our proof that Fourier matrices are not rigid involves extending Theorem 1.6 to all values of $N$. The diagonalization trick gives that $N \times N$ circulant matrices are not rigid when $N$ is well-factorable. We then show that for $N' < \frac{N}{2}$, we can rescale the columns of the $N' \times N'$ Fourier matrix and embed it into an $N \times N$ circulant matrix. As long as $N'$ is not too much smaller than $N$ (say $N' > \frac{N}{(\log N)^{2/3}}$), we get that the $N' \times N'$ Fourier matrix is not rigid. Thus, for each well-factorable $N$ and all $N'$ in the range $\frac{N}{(\log N)^{2/3}} < N' < \frac{N}{2}$, the $N' \times N'$ Fourier transform matrix is not rigid. We then use a number theoretic result of [BH98] to show that the gaps between well-factorable integers are not too large. Thus, the above intervals cover all integers as $N$ runs over all well-factorable numbers, finishing the proof.

1.4 Organization

In Section 2 we introduce notation and prove several basic results that we will use throughout the paper. In Section 3 we show that Hadamard and several closely related families of matrices are not rigid. In Section 4 we show that $N \times N$ Fourier matrices are not rigid when $N$ satisfies certain number-theoretic properties. In Section 5 we complete the proof that all Fourier matrices are not rigid. We then deduce that all Toeplitz matrices are not rigid. In Section 6 we use the results from the previous section to show that group algebra matrices for abelian groups are not rigid. Finally, in Section 7 we discuss a few open questions and possible directions for future work.

2 Preliminaries

Throughout this paper, we let $d \geq 2$ be an integer and $\omega = e^{\frac{2\pi i}{d}}$ be a primitive $d$th root of unity. When we consider an element of $\mathbb{Z}_d^m$, we will view it as an $n$-tuple with entries in the range $[0, d - 1]$. When we say a list of $d^n$ elements $x_1, \ldots , x_{d^n}$ is indexed by $\mathbb{Z}_d^m$, we mean that each $x_i$ is labeled with an element of $\mathbb{Z}_d^m$ such that all labels are distinct and the labels of $x_1, \ldots , x_{d^n}$ are in lexicographical order.

2.1 Basic Notation

We will frequently work with tuples, say $I = (i_1, \ldots , i_n) \in \mathbb{Z}_d^m$. Below we introduce some notation for dealing with tuples that will be used later on.

**Definition 2.1.** For a tuple $I$, we let $I^i$ denote its $i$th entry. For instance if $I = (i_1, \ldots , i_n)$ then $I^k = i_k$. 4
Definition 2.2. For an $n$-tuple $I = (i_1, i_2, \ldots, i_n)$, define the polynomial over $n$ variables $x^I = x_1^{i_1} \ldots x_n^{i_n}$.

Definition 2.3. For $\omega$ a $d$th root of unity and an $n$-tuple $I = (i_1, i_2, \ldots, i_n) \in \mathbb{Z}_d^n$, we define $\omega^{|I|} = (\omega^{i_1}, \ldots, \omega^{i_n})$.

Definition 2.4. For a function $f : \mathbb{Z}_d^n \to \mathbb{C}$, define the $n$-variable polynomial $P_f$ as

$$P_f = \sum_{I \in \mathbb{Z}_d^n} f(I)x^I$$

Definition 2.5. For an $n$-tuple $I = (i_1, i_2, \ldots, i_n)$, we define the set $\text{perm}(I)$ to be a set of $n$-tuples consisting of all distinct permutations of the entries of $I$. Similarly, for a set of $n$-tuples $S$, we define $\text{perm}(S)$ to be the set of all $n$-tuples that can be obtained by permuting the entries of some element of $S$.

Definition 2.6. We say a set $S \subseteq \mathbb{Z}_d^n$ is symmetric if for any $I \in S$, $\text{perm}(I) \subseteq S$.

Definition 2.7. For a set of $n$-tuples $S$, let $\text{red}(S)$ denote the set of equivalence classes under permutation of entries in $S$. Let $\text{rep}(S)$ be a set of $n$-tuples formed by taking one representative from each equivalence class in $\text{red}(S)$ (note $\text{rep}(S)$ is not uniquely determined but this will not matter for our use).

Note that if $\text{rep}(S) = \{I_1, \ldots, I_k\}$, then the sets $\text{perm}(I_1), \text{perm}(I_2), \ldots, \text{perm}(I_k)$ are disjoint and their union contains $S$. If the set $S$ is symmetric then their union is exactly $S$.

### 2.2 Special Families of Matrices

We now define notation for working with a few special families of matrices.

Definition 2.8. An $N \times N$ matrix $M$ is called a Toeplitz matrix if $M_{ij}$ depends only on $i - j$. An $N \times N$ matrix $M$ is called a Hankel matrix if $M_{ij}$ depends only on $i + j$. Note that the rows of any Toeplitz matrix can be permuted to obtain a Hankel matrix so any non-rigidity results we show for one family also hold for the other.

Definition 2.9. For an abelian group $G$ and a function $f : G \to \mathbb{C}$, let $M_G(f)$ denote the $|G| \times |G|$ matrix (over $\mathbb{C}$) whose rows and columns are indexed by elements $x, y \in G$ and whose entries are given by $M_{xy} = f(x + y)$. When it is clear what $G$ is from context, we will simply write $M(f)$. We let $V_G$ denote the family of matrices $M_G(f)$ as $f$ ranges over all functions from $G$ to $\mathbb{C}$. We call $V_G$ the family of adjusted group algebra matrices for the group $G$. When $G$ is a cyclic group, we call the matrices in $V_G$ adjusted-circulant.

Compared to the usual group algebra (and circulant) matrices defined by $M_{xy} = f(x - y)$, the matrix $M_G(f)$ differs only in a permutation of the rows. In the proceeding sections, we will work with $M_G(f)$ for technical reasons, but it is clear that the same non-rigidity results hold for the usual group algebra matrices. Similarly, we will use adjusted-circulant and Hankel matrices as it is clear that the same non-rigidity results hold for circulant and Toeplitz matrices. Also note that adjusted-circulant matrices are a special case of Hankel matrices.

Definition 2.10. Let $H_{d,n}$ denote the $d^n \times d^n$ Hadamard matrix, i.e. the matrix whose rows and columns are indexed by $n$-tuples $I, J \in \mathbb{Z}_d^n$ and whose entries are $H_{IJ} = \omega^{I \cdot J}$ where $\omega = e^{2\pi i / d}$. When $n = 1$, we define $F_d = H_{d,1}$ and call $F_d$ a Fourier matrix.

### 2.3 Matrix Rigidity

Here, we review basic notation for matrix rigidity.

Definition 2.11. For a matrix $M$ and a real number $r$, we define $R_M(r)$ to be the smallest number $s$ for which there exists a matrix $A$ with at most $s$ nonzero entries and a matrix $B$ of rank at most $r$ such that $M = A + B$.

If $R_M(r) \geq s$, we say $M$ is $(r, s)$-rigid.
Let $\text{Claim 2.16.}$ I, $J$ naturally be indexed by tuples $H_{d,n}$.

Next, we mention several basic results that will be useful in the proofs later on.

**2.4 Preliminary Results**

Let $\text{Claim 2.17.}$ We verify that $F_d F_d^* = d^n I$. Then $D$ is a diagonal matrix with diagonal entries $d^n P_f (\omega^{[I]} )$ as $J$ ranges over $\mathbb{Z}_d^n$.

**Proof.** First, we analyze the product $\sum_{I' \in \mathbb{Z}_d^n} f(I + I') \omega^{-I-J} = \omega^{-I-J} \sum_{I' \in \mathbb{Z}_d^n} f(I + I') \omega^{(I'+I) \cdot J} = \omega^{-I-J} P_f (\omega^{[J]} )$

Therefore, the columns of $M_{\mathbb{Z}_d^n} (f) H_{d,n}$ are multiples of the columns of $H_{d,n}^*$. In fact, the column of $M_{\mathbb{Z}_d^n} (f) H_{d,n}$ indexed by $J$ is $P_f (\omega^{[J]} )$ times the corresponding column of $H_{d,n}^*$. Since $H_{d,n} H_{d,n}^* = d^n I$, $D$ must be a diagonal matrix whose entries on the diagonal are $d^n P_f (\omega^{[J]} )$ as $J$ ranges over $\mathbb{Z}_d^n$. 

Plugging $n = 1$ into the above gives:

**Claim 2.16.** Let $M$ be a $d \times d$ adjusted-circulant matrix. Then $F_d M F_d$ is a diagonal matrix.

Claim 2.15 gives us a characterization of the rank of matrices of the form $M_{\mathbb{Z}_d^n} (f)$.

**Claim 2.17.** Let $f : \mathbb{Z}_d^n \rightarrow \mathbb{C}$ be a function. Let $\omega$ be a $d^{th}$ root of unity and say $P_f = \sum_{I \in \mathbb{Z}_d^n} f(I) x^I$ has $C$ roots among the set $\{ (\omega^i, \ldots, \omega^{i^n}) | (i_1, \ldots, i_n) \in \mathbb{Z}_d^n \}$. Then $\text{rank} (M_{\mathbb{Z}_d^n} (f)) = d^n - C$.

**Proof.** Consider the product $D = H_{d,n} M_{\mathbb{Z}_d^n} (f) H_{d,n}$. Note that $H_{d,n}$ is clearly invertible by Claim 2.14. Therefore, it suffices to compute the rank of $D$. By Claim 2.15, $D$ must be a diagonal matrix whose entries on the diagonal are $d^n P_f (\omega^{[J]} )$ as $J$ ranges over $\mathbb{Z}_d^n$. The rank of $D$ is the number of nonzero diagonal entries which is simply $d^n - C$.

As mentioned in the introduction, we can relate the rigidity of a matrix to the rigidity of matrices that it diagonalizes.

**Lemma 2.18.** If $B = A^* D A$ where $D$ is a diagonal matrix and $r_A (r) \leq s$ then $r_B (2r) \leq s^2$. The same inequality holds also for $B^* = ADA$. 

Proof. Let $E$ be the matrix with at most $s$ nonzero entries in each row and column such that $A − E$ has rank at most $r$. We have

$$B − E^*DE = A^*D(A − E) + (A^* − E^*)DE$$

Since $\text{rank}(A − E) \leq r$, $\text{rank}(B − E^*DE) \leq 2r$. Also, $E^*DE$ has at most $s^2$ nonzero entries in each row and column so $r_E(2r) \leq s^2$. The second part can be proved in the exact same way with $A^*$ replaced by $A$. \hfill \square

In light of Lemma 2.18 Claim 2.16 and Claim 2.14 proving non-rigidity for $d \times d$ circulant matrices reduces to proving non-rigidity for $F_d$ and proving non-rigidity for group algebra matrices for $\mathbb{Z}_d^2$ reduces to proving non-rigidity for $H_{d,n}$. Below, we show that these statements are actually equivalent.

Claim 2.19. It is possible to rescale the rows and columns of $H_{d,n}$ to get a matrix of the form $M_{\mathbb{Z}_d^2}(f)$ for some symmetric function $f : \mathbb{Z}_d^2 \to \mathbb{C}$. In particular, it is possible to rescale the rows and columns of $F_d$ to get an adjusted-circulant matrix.

Proof. Let $\zeta$ be such that $\zeta^2 = \omega$. Multiply each row of $H_{d,n}$ by $\zeta^{(I,1)}$ and each column by $\zeta^{(J,1)}$ to get a matrix $H'$. We have

$$H'_{IJ} = \zeta^{(I+J)·(I+J)}$$

For a tuple $x = (x_1, \ldots, x_d) \in \mathbb{Z}_d^n$, we define $f(x) = \zeta^{x_1^2 + \cdots + x_n^2}$. To complete the proof, it suffices to show that $f : \mathbb{Z}_d^d \to \mathbb{C}$ is well defined. To do this, we will show that $\zeta^{x^2}$ depends only on the residue of $x$ mod $d$. If $d$ is odd, we can choose $\zeta$ to be a $d$th root of unity and the claim is clear. If $d$ is even, $\zeta^{(x+d)^2} = \zeta^x \zeta^{2dx+d^2}$ but since $2dx + d^2$ is a multiple of $2d$, $\zeta^{2dx+d^2} = 1$ and thus $\zeta^{(x+d)^2} = \zeta^x$. \hfill \square

3 Non-rigidity of Generalized Hadamard Matrices

In this section, we show that the Hadamard matrix $H_{d,n}$ becomes highly non-rigid for large values of $n$. The precise result is stated below.

Theorem 3.1. Let $N = d^n$ for positive integers $d,n$. Let $0 < \epsilon < 0.1$ and assume $n \geq d^2(\log d)^2$. Then $r_{H_{d,n}}(N^{1−\frac{\epsilon^2}{\log d}}) \leq N^\epsilon$.

First we prove a few lemmas about symmetric polynomials that we will use in the proof of Theorem 3.1.

Lemma 3.2. Let $T_m$ denote the set of tuples in $\mathbb{Z}_d^n$ such that at least $m$ entries are equal to 0. Say $\text{rep}(T_m) = \{I_1, \ldots, I_k\}$. Consider the polynomials $P_1(x_1, \ldots, x_n), \ldots, P_k(x_1, \ldots, x_n)$ defined by

$$P_i(x_1, \ldots, x_n) = \sum_{I \in \text{perm}(I_i)} x^I$$

For any complex numbers $y_1, \ldots, y_m$, and any polynomial $Q(x_{m+1}, \ldots, x_n)$ that is symmetric and degree at most $d−1$ in each of its variables, there exist coefficients $c_1, \ldots, c_k$ such that

$$Q(x_{m+1}, \ldots, x_n) = \sum c_i P_i(y_1, \ldots, y_m, x_{m+1}, \ldots, x_n)$$

Proof. It suffices to prove the statement for all $Q$ of the form

$$\sum_{I'^{·'} \in \text{perm}(I')} x^{I'·'}$$

where $I' \in \mathbb{Z}_d^{n−m}$. We will prove this by induction on the degree. Clearly one of the $I_i$ is $(0,0\ldots0)$, so one of the polynomials $P_i(x_1, \ldots, x_n)$ is constant. This finishes the case when $Q$ has degree 0. Now we do the
induction step. Note that we can extend $I'$ to an element of $T_m$ by setting the first $m$ entries equal to 0. Call this extension $I$ and say that $I \in \perm(I_i)$. We have

$$
\sum_{I'' \in \perm(I')} x^{I''} = P_i(y_1, \ldots, y_m, x_{m+1}, \ldots, x_n) - R(y_1, \ldots, y_m, x_{m+1}, \ldots, x_n)
$$

$R(y_1, \ldots, y_m, x_{m+1}, \ldots, x_n)$, when viewed as a polynomial in $x_{m+1}, \ldots, x_n$ (since $y_1, \ldots, y_m$ are complex numbers that we can plug in), is symmetric and of lower degree than the left hand side. Thus, using the induction hypothesis, we can write $R$ in the desired form. This completes the induction step. \qed

The key ingredient in the proof of Theorem 3.1 is the following lemma which closely resembles the main result in [DE17], but deals with matrices over $\mathbb{C}$.

Lemma 3.3. Let $f : \mathbb{Z}_d^n \to \mathbb{C}$ be a symmetric function on the $n$ variables. Let $N = d^n$. Let $0 < \epsilon < 0.1$ and assume $n \geq \frac{d^2(\log d)^2}{\epsilon^2}$. Then $t_{M(f)}(N^{1 - \frac{d}{2\log d}}) \leq N^\epsilon$.

Let $\delta = \epsilon^2$, $m = \lceil n(1 - \frac{1}{\sqrt{\log d}}) \rceil$ and let $S$ denote the set of all tuples $(i_1, i_2, \ldots, i_n) \in \mathbb{Z}_d^n$ such that the entries indexed $1, 2, \ldots, m$ are equal to 0, the entries indexed $m + 1, \ldots, 2m$ are equal to 1 and in general for $0 \leq i \leq d - 1$, the entries indexed $im + 1, \ldots, (i + 1)m$ are equal to $i$. Note $|S| = d^{n - dm} \approx d^{\delta n} = N^\epsilon$ (since $n - dm$ is approximately $\delta n$).

The main idea will be to change $f$ in a small number of locations so that it has many zeros in the set $\{\omega[I] | I \in S \}$ in order to make use of Claim 2.17. More precisely, first we will change $f$ to $f'$ by changing its values in at most $N^\epsilon$ places so that $f'$ is still symmetric in all of the variables and

$$
P_{f'}(\omega[I]) = 0 \forall I \in S
$$

Note that although the size of $S$ is small, the fact that $f'$ is symmetric implies that $f'$ also vanishes on $\perm(S)$, which covers almost all of $\mathbb{Z}_d^n$. Once we have shown the above, we quantitatively bound the number of entries changed between $M(f)$ and $M(f')$ and also the rank of $M(f')$ to complete the proof of Lemma 3.3. To do the first part, we need the following sub-lemma.

Lemma 3.4. Let $T$ denote the set of all tuples $(i_1, i_2, \ldots, i_n) \in \mathbb{Z}_d^n$ such that at least $n(1 - \delta)$ of the entries are 0. By changing the values of $f$ only on elements of $T$, we can obtain $f'$ satisfying

$$
P_{f'}(\omega[I]) = 0 \forall I \in S
$$

(1)

Proof. We interpret (1) as a system of linear equations where the unknowns are the values of $f'$ at various points. Let $\rep(T) = \{J_1, J_2, \ldots, J_k\}$ for $J_1, J_2, \ldots, J_k \in T$. Since we must maintain that $f'$ is symmetric, there are essentially $k$ variables each corresponding to an equivalence class of tuples under permutations. Each equivalence class is of the form $\perm(J_j)$ and we denote the corresponding variable by $m_j$. The system of equations in (1) can be rewritten in the form

$$
\sum_{j=1}^{k} m_j \sum_{J \in \perm(J_j)} \omega^{J} + \sum_{J \notin T} f(J') \omega^{J} = 0 \forall I \in S
$$

If we let $\rep(S) = \{I_1, I_2, \ldots, I_l\}$, the system has exactly $l$ distinct equations corresponding to each element of $\rep(S)$ due to our symmetry assumptions. Let $M$ denote the $l \times k$ coefficient matrix represented by $M_{ij} = \sum_{J \in \perm(J_j)} \omega^{I_i - J}$. To show that the system has a solution, it suffices to show that the column span of $M$ is full. This is equivalent to showing that for each $i = 1, 2, \ldots, l$ there exist coefficients $a_1, a_2, \ldots, a_k$ such that
\[
\sum_{j=1}^k a_j \cdot \sum_{J \in \text{perm}(J_j)} \omega^{I_j \cdot J} \neq 0 \\
\sum_{j=1}^k a_j \cdot \sum_{J \in \text{perm}(J_j)} \omega^{I_j \cdot J'} = 0 \ \forall i' \neq i
\]

Fix an index \(i_0\). We can view each equation above as a polynomial in \(\omega^{[I_i]}\) given by

\[
P(x_1, \ldots, x_n) = \sum_{j=1}^k a_j \sum_{J \in \text{perm}(J_j)} x^J
\]

and the problem becomes equivalent to constructing a polynomial that vanishes on \(\omega^{[I_i]}\) if and only if \(i \neq i_0\). Note that only the entries \(x_{dm+1}, \ldots, x_n\) matter as we have \(x_1 = \cdots = x_m = 1, \ldots, x_{(d-1)m+1} = \cdots = x_{dm} = \omega^{d-1}\) for all points we consider.

For \(I_i = (i_1, i_2, \ldots, i_n)\), let \(I'_i\) denote the sub-tuple \((i_{dm+1}, \ldots, i_n)\). The problem is equivalent to constructing a polynomial

\[
Q(x_{dm+1}, \ldots, x_n) = P(1, 1, \ldots, \omega^{d-1}, \ldots, \omega^{d-1}, x_{dm+1}, \ldots, x_n)
\]

such that \(Q\) vanishes on \(\omega^{[I'_i]}\) if and only if \(i \neq i_0\).

Lemma 3.2 implies that by choosing the coefficients \(a_1, \ldots, a_k\), we can make \(Q\) be any polynomial that is symmetric in \(x_{dm+1}, \ldots, x_n\) and degree at most \(d-1\) in each of the variables.

Now consider the polynomial

\[
Q_{i_0}(x_{dm+1}, \ldots, x_n) = \sum_{I' \in \text{perm}(I'_i)} \left( \frac{x_{dm+1}^d - 1}{x_{dm+1} - \omega^{I'}} \right) \cdots \left( \frac{x_n^d - 1}{x_n - \omega^{I'(n-dm)}} \right)
\]

(note this is a polynomial with coefficients in \(\mathbb{C}\) since each of the factors reduces to a degree \(d-1\) polynomial)

It is clear that the above polynomial is symmetric in all of the variables and satisfies the degree constraint so we know we can choose suitable coefficients \(a_1, \ldots, a_k\). We claim that the polynomial we construct does not vanish on \(\omega^{[I'_i]}\) but vanishes on \(\omega^{[I'_i]}\) for \(i \neq i_0\). Indeed, the product

\[
\left( \frac{x_{dm+1}^d - 1}{x_{dm+1} - \omega^{I'}} \right) \cdots \left( \frac{x_n^d - 1}{x_n - \omega^{I'(n-dm)}} \right)
\]

is 0 if and only if \((x_{dm+1}, \ldots, x_n) \neq I'\). However, there is exactly one \(I' \in \text{perm}(I'_{i_0})\) with \(I' = I'_{i_0}\) and none with \(I' = I'_i\) for \(i \neq i_0\) since \(I_1, I_2, \ldots, I_i\) are representatives of distinct equivalence classes under permutation of entries. This means that the polynomial \(Q_{i_0}\) we constructed has the desired properties and completes the proof that the system is solvable.

**Proof of Lemma 3.3.** Since \(M(f) = (M(f) - M(f')) + M(f')\), to complete the proof of Lemma 3.3, it suffices to bound the number of nonzero entries in \(M(f) - M(f')\) and the rank of \(M(f')\).

The number of nonzero entries in each row and column of \((M(f) - M(f'))\) is at most \(|T|\). This is exactly the number of elements of \(\mathbb{Z}^n_d\) with at least \(n(1 - \delta)\) entries equal to 0. Using standard tail bounds on the binomial distribution, the probability of a random \(n\)-tuple having at least \(m0s\) is at most

\[
e^{-nD(1-\delta)\frac{1}{2d}} = e^{-n\left((1-\delta)\log(d(1-\delta)+\delta \log(\frac{d}{\delta}))\right) = d^{-n(1-\delta)}e^{-n\left((1-\delta)\log(1-\delta)+\delta \log(\frac{d}{\delta})\right)}}
\]
where $D(\cdot || \cdot)$ denotes KL-divergence. For $\delta < 0.01$, the above is at most $d^{-n(1-\sqrt{\delta})}$ and thus we change at most $d^{\epsilon n}$ entries in each row and column.

By Claim 2.17, the rank of $M(f')$ is at most $d^n - |\text{perm}(S)|$. Equivalently, this is the number of $n$-tuples such that some element in $\{0, 1, \ldots, d-1\}$ appears less than $(1-\frac{4\epsilon}{d^2})n$ times. We use Hoeffding’s inequality and then union bound over the $d$ possibilities to get the probability that a randomly chosen $n$-tuple in $\mathbb{Z}_d^n$ is outside $S$ is at most

$$de^{-\frac{4\epsilon n}{d^2}} = e^{-\frac{4\epsilon n}{d^2} + \log d}$$

When $n > \frac{d^2(\log d)^2}{\epsilon^2}$, the above is at most $d^{\epsilon n}$ and thus the rank of $M(f')$ is at most $d^{(1-\frac{4\epsilon}{d^2})n}$, completing the proof of Lemma 3.3.

Proof of Theorem 3.1. Applying Claim 2.19 and Lemma 3.3 we immediately get the desired.

Using Theorem 3.1, Lemma 2.18, and Claim 2.15, we get the following result which extends Lemma 3.3 to matrices where $f$ is not symmetric.

**Corollary 3.5.** For any function $f : \mathbb{Z}_d^n \rightarrow \mathbb{C}$ and any $0 < \epsilon < 0.1$ such that $n \geq \frac{d^2(\log d)^2}{\epsilon^2}$, we have

$$\text{r}_M(f)(2N^{1-\frac{4\epsilon}{d^2}}) \leq N^{2\epsilon}$$

where $N = d^n$.

### 4 Non-rigidity for Fourier Matrices of Well-Factorable Size

Our goal in this section is to show that we can find infinitely many values of $N$ for which the Fourier matrix $F_N$ is highly non-rigid. The integers $N$ we analyze will be products of many distinct primes $q_i$ with the property that $q_i - 1$ is very smooth (has all prime factors small). For these values of $N$, we can decompose the matrix $F_N$ into several submatrices that are closely related to Hadamard matrices. We then apply the results from the previous section to show that each submatrix is non-rigid and aggregate over the submatrices to conclude that $F_N$ is non-rigid.

We first show precisely how to construct $N$. The properties that we want $N$ to have are stated in the following two definitions.

**Definition 4.1.** We say a prime $q$ is $(\alpha, x)$-good if the following properties hold.

- $x^{0.999} \leq q \leq x$
- All prime powers dividing $q - 1$ are at most $x^\alpha$

**Definition 4.2.** We say an integer $N$ is $(l, \alpha, x)$-factorable if the following properties hold.

- $N = q_1 \ldots q_l$ where $q_1, \ldots, q_l$ are distinct primes
- $q_1, \ldots, q_l$ are all $(\alpha, x)$-good

To show the existence of $(l, \alpha, x)$-factorable integers, it suffices to show that there are many $(\alpha, x)$-good primes. This is captured in the following lemma.

**Lemma 4.3.** There exists a fixed constant $C_0$ such that for any parameter $\alpha > 0.2961$ and sufficiently large $x$ (possibly depending on $\alpha$), there are at least $\frac{x}{(\log x)^{C_0}}$ distinct $(\alpha, x)$-good primes.

The proof of Lemma 4.3 relies on the following result from analytic number theory, found in [BH98], that allows us to find a large set of primes $q_i$ for which $q_i - 1$ is very smooth.

10
Definition 4.4. For a positive integer \( m \), let \( P^+(m) \) denote the largest prime factor of \( m \). For a fixed positive integer \( a \), let

\[
\pi_a(x, y) = |\{p|a < p \leq x, P^+(p - a) \leq y\}|
\]

where \( p \) ranges over all primes. In other words, \( \pi_a(x, y) \) is the number of primes at most \( x \) such that \( p - a \) is \( y \)-smooth.

Theorem 4.5 (\([BH98]\)). There exist constants \( x_0, C \) such that for \( \beta = 0.2961 \), \( x > x_0 \) and \( y \geq x^\beta \) we have

\[
\pi_1(x, y) > \frac{x}{(\log x)^C}
\]

Proof of Lemma 4.3. Let \( y = x^\beta \) where \( \beta = 0.2961 \). By Theorem 4.5, for sufficiently large \( x \), we can find at least \( \left\lfloor \frac{x}{(\log x)^{0.999}} \right\rfloor \) primes \( p_1, \ldots, p_l \) between \( x^{0.999} \) and \( x \) such that all prime factors of \( p_i - 1 \) are at most \( x^\beta \). Eliminate all of the \( p_i \) such that one of the prime powers in the prime factorization of \( p_i - 1 \) is more than \( x^\alpha \), where \( x \) is an absolute constant. For sufficiently large \( x \), the number of \((\alpha, x)\)-good primes is at least

\[
\frac{x}{(\log x)^C} - x^{0.999} - x^{1-\alpha+\beta} \log x \geq \frac{x}{2(\log x)^C}
\]

Thus, there are at most \( x^\beta \log x \) different prime powers bigger than \( x^\alpha \) that divide some \( p_i - 1 \). Each of these prime powers can divide at most \( x^{1-\alpha} \) of the elements \( \{p_1, \ldots, p_l\} \), so in total, we eliminate at most \( x^{1-\alpha+\beta} \log x \) of the \( p_i \). Thus, for sufficiently large \( x \), the number of \((\alpha, x)\)-good primes is at least

\[
\frac{x}{(\log x)^C} - x^{0.999} - x^{1-\alpha+\beta} \log x \geq \frac{x}{2(\log x)^C}
\]

For simplicity, we will set \( \alpha = 0.3 \) by default.

Definition 4.6. A prime is said to be \( x \)-good if it is \( (0.3, x) \)-good. An integer \( N \) is said to be \((l, x)\)-factorable if it is \((l, 0.3, x)\)-factorable.

Lemma 4.3 implies that for all sufficiently large \( x \) and \( l \leq \frac{x}{(\log x)^{0.999}} \), we can find \((l, x)\)-factorable integers. We now show that if we choose \( x \) sufficiently large and \( N \) to be \((l, x)\)-factorable for some \( x^{0.99} \leq l \leq x^{0.993} \), then \( F_N \) is highly non-rigid.

Theorem 4.7. Let \( 0 < \epsilon < 0.1 \) be given. For \( x \) sufficiently large and \( N \) a \((l, x)\)-factorable number for \( x^{0.99} \leq l \leq x^{0.993} \), we must have

\[
\tau_{F_N}\left(\frac{N}{2^{41(\log N)^{0.99} \text{harm}}}\right) \leq N^{4\epsilon}
\]

In order to prove Theorem 4.7, we will first prove a series of preliminary results that characterize the structure of Fourier and Hadamard matrices.

4.1 Structure of Hadamard and Fourier Matrices

Lemma 4.8. Let \( n = x_1x_2 \cdots x_j \) for pairwise relatively prime positive integers \( x_1, \ldots, x_j \). There exists a permutation of the rows and columns of \( F_n \), say \( F' \), such that

\[
F' = F_{x_1} \otimes \cdots \otimes F_{x_j}
\]

where \( \otimes \) denotes the Kronecker product.

Proof. Let \( \gamma \) be a primitive \( n^{\text{th}} \) root of unity. For \( i = 1, 2, \ldots, j \), let \( \gamma_i = \gamma^{c_i} \) mod \( x_i \), where \( c_i \) is chosen such that \( c_i \frac{n}{x_i} \equiv 1 \) mod \( x_i \). Note this is possible since \( x_1, \ldots, x_j \) are pairwise relatively prime. \( \gamma_i \) is a primitive \( x_i^{\text{th}} \) root of unity.

\[\text{[BH98] proves the same inequality with } \pi_a(x, y) \text{ for any integer } a \text{ where } x_0 \text{ may depend on } a \text{ and } C \text{ is an absolute constant.}\]
Now by the Chinese remainder theorem, there is a ring isomorphism between $\mathbb{Z}_n$ and $\mathbb{Z}_{x_1} \times \cdots \times \mathbb{Z}_{x_j}$. We can thus view $F_n$ as a matrix whose rows and columns are indexed by elements of $\mathbb{Z}_{x_1} \times \cdots \times \mathbb{Z}_{x_j}$ and such that the entry $F_{n|AB}$ corresponding to tuples $A = (a_1, \ldots, a_j)$ and $B = (b_1, \ldots, b_j)$ is $\gamma^c$ where $c$ is the unique element of $\mathbb{Z}_n$ with $c \equiv a_ib_i \mod x_i$ for all $i$.

For each matrix $F_{x_i}$ its rows and columns are labeled with elements of $\mathbb{Z}_{x_i}$, and its entries are $F_{x_i|ab} = \gamma_i^{a_ib_i}$. Thus in the Kronecker product, the rows and columns are labeled with elements of $\mathbb{Z}_{x_1} \times \cdots \times \mathbb{Z}_{x_j}$ such that the entry corresponding to tuples $(a_1, \ldots, a_j)$ and $(b_1, \ldots, b_j)$ is

$$
\gamma_1^{a_1b_1} \cdots \gamma_j^{a_jb_j} = \gamma_i^{c_1a_1b_1 \mod x_1 + \cdots + c_ja_jb_j \mod x_j}
$$

For each $x_i$, we compute the residue of the exponent in the above expression $\mod x_i$. The term $c_i a_i b_i \mod x_i$ is congruent to $a_i b_i$ by definition and all other terms are $0$ so the sum is congruent to $a_i b_i \mod x_i$. Thus, for some permutation of the rows and columns of $F_n$, it is equal to the Kronecker product $F_{x_1} \otimes \cdots \otimes F_{x_j}$, as desired.

**Lemma 4.9.** Let $M = A \otimes B$ where $A$ is an $m \times m$ matrix and $B$ is an $n \times n$ matrix. For any two integers $r_1, r_2$ we have

$$
r_M(r_1n + r_2m) \leq r_A(r_1)r_B(r_2)
$$

**Proof.** The proof of this lemma is similar to the proof of Lemma 2.18. There are matrices $E, F$ with at most $r_A(r_1)$ and $r_B(r_2)$ nonzero entries respectively such that $\text{rank}(A + E) \leq r_1$ and $\text{rank}(B + F) \leq r_2$. We will now show that $\text{rank}(M - E \otimes F) \leq r_1n + r_2m$. Indeed

$$
M - E \otimes F = (A + E) \otimes B - E \otimes (B + F)
$$

and the right hand side of the above has rank at most $r_1n + r_2m$ since rank multiplies under the Kronecker product. Clearly $E \otimes F$ has at most $r_A(r_1)r_B(r_2)$ nonzero entries in each row and column so we are done. \qed

**Lemma 4.10.** Consider the matrix

$$
A = (F_{t_1} \otimes \cdots \otimes F_{t_1}) \otimes \cdots \otimes (F_{t_n} \otimes \cdots \otimes F_{t_n})
$$

Let $0 < \epsilon < 0.1$ be some chosen parameter. Assume $a_i \geq \frac{\epsilon^2(\log t_i)^2}{\epsilon^2}$ for all $i$. Let $P = t_1^{a_1} \cdots t_n^{a_n}$. Then

$$
r_A \left( P \sum_{i=1}^{n} \left( \frac{1}{t_i^{a_1} \frac{\epsilon^2}{\log t_i}} \right) \right) \leq P^\epsilon
$$

**Proof.** Note $F_{t_1} \otimes \cdots \otimes F_{t_1} = H_i^{a_1}$. Now we apply Theorem 3.1 to each of the $n$ terms. Let $T_{t_i, a_i} = F_{t_i} \otimes \cdots \otimes F_{t_i}$. We have

$$
r_{T_{t_i, a_i}} \left( \frac{a_i}{t_i} \frac{1 - \epsilon^2}{\log t_i} \right) \leq t_i^{a_i \epsilon}
$$

Now we combine the above estimates over all $i$ by repeatedly applying Lemma 4.9. We get

$$
r_A \left( \sum_{i=1}^{n} \frac{a_i}{t_i} \frac{1 - \epsilon^2}{\log t_i} \left( \frac{P}{t_i^{a_i}} \right) \right) \leq P^\epsilon
$$

This easily rearranges into the desired. \qed

12
4.2 Proof of Theorem 4.7

To complete the proof of Theorem 4.7, we will break \( F_N \) into submatrices, show that each submatrix is non-rigid using techniques from the previous section, and then combine our estimates to conclude that \( F_N \) is non-rigid. Recall that \( N \) is \((l, x)\)-factorable with \( x^{0.99} \leq l \leq x^{0.993} \), meaning \( N = q_1 q_2 \ldots q_l \) for some distinct primes \( q_1, \ldots, q_l \) where \( q_i - 1 \) has no large prime power divisors for all \( i \). Let \( \gamma \) be a primitive \( N^{th} \) root of unity.

**Definition 4.11.** For a subset \( S \subset [l] \) define \( \text{mult}_N(S) = \prod_{s \in S} q_s \) and \( \text{fact}_N(S) = \prod_{s \in S} (q_s - 1) \).

**Definition 4.12.** For all \( S \subset [l] \) we will define \( T_S \) as the subset of \([N] \times [N]\) indexed by \((i, j)\) such that

\[
ij \not\equiv 0 \pmod{q_s} \quad \forall s \in S
\]

\[
ij \equiv 0 \pmod{q_s} \quad \forall s \not\in S
\]

Note that as \( S \) ranges over all subsets of \([l]\), the sets \( T_S \) form a partition of \([N] \times [N]\).

For each \( S \), we will divide the set \( T_S \) into submatrices such that when filled with the corresponding entries of \( F_N \), we can apply Lemma 4.10 to show that each submatrix is nonrigid. The key intuition is that for a given prime \( q_i \), once we restrict to nonzero residues, the multiplicative subgroup actually has the additive structure of \( \mathbb{Z}_{q_i - 1} \). Since \( q_i - 1 \) is smooth, \( \mathbb{Z}_{q_i - 1} \) is a direct sum of cyclic groups of small order.

**Definition 4.13.** For all \( S \subset [l] \), we define the \( \text{fact}_N(S) \times \text{fact}_N(S) \) matrix \( M(S) \) as follows. Let \( R_S \) be the set of residues modulo \( \text{mult}_N(S) \) that are relatively prime to \( \text{mult}_N(S) \). Note that \( |R_S| = \text{fact}_N(S) \). Each row and each column of \( M(S) \) is indexed by an element of \( R_S \) and the entry in row \( i \) and column \( j \) is \( \theta^{ij} \) where \( \theta \) is a primitive \( \text{mult}_N(S) \) root of unity. The exact order of the rows and columns will not matter for our uses. Note that replacing \( \theta \) with \( \theta^k \) for \( k \) relatively prime to \( \text{mult}_N(S) \) simply permutes the rows so it does not matter which root of unity we choose.

**Lemma 4.14.** Consider the set of entries in \( F_N \) indexed by elements of \( T_S \). We can partition this set into \( \prod_{s \not\in S} (2q_s - 1) \) submatrices each of size \( \text{fact}_N(S) \times \text{fact}_N(S) \) that are equivalent to \( M(S) \) up to some permutation of rows and columns.

**Proof.** In \( T_S \), for each prime \( q_s \) with \( s \not\in S \), there are \( 2q_s - 1 \) choices for what \( i \) and \( j \) are \( \pmod{q_s} \). Now fix the choice of \( i, j \pmod{q_s} \) for all \( s \not\in S \). Say we restrict to indices with \( i \equiv c_1 \pmod{\prod_{s \not\in S} q_s} \) and \( j \equiv c_2 \pmod{\prod_{s \not\in S} q_s} \).

We are left with a \( \text{fact}_N(S) \times \text{fact}_N(S) \) matrix, call it \( A \), where \( i \) and \( j \) run over all residues modulo \( \text{mult}_N(S) \) that are relatively prime to \( \text{mult}_N(S) \). Naturally, label all rows and columns of this matrix by what the corresponding indices \( i \) and \( j \) are modulo \( \text{mult}_N(S) \). For a row labeled \( a \) and a column labeled \( b \), we compute the entry \( A_{ab} \). The value is \( \gamma^{a'b'} \) where \( a' \) is the unique element of \( \mathbb{Z}_N \) such that \( a' \equiv a \pmod{\text{mult}_N(S)} \) and \( a' \equiv c_1 \pmod{\prod_{s \not\in S} q_s} \) and \( b' \) is defined similarly. We have

\[
a' \cdot b' \equiv ab \pmod{\text{mult}_N(S)}
\]

\[
a' \cdot b' \equiv c_1 c_2 \equiv 0 \pmod{\prod_{s \not\in S} q_s}
\]

Therefore

\[
a'b' \equiv k \prod_{s \not\in S} q_s a b \pmod{\text{mult}_N(S)}
\]

where \( k \) is defined as an integer such that \( k \prod_{s \not\in S} q_s \equiv 1 \pmod{\text{mult}_N(S)} \). Note that \( k \) clearly exists since \( \prod_{s \not\in S} q_s \) and \( \text{mult}_N(S) \) are relatively prime. Since \( \gamma^k \prod_{s \not\in S} q_s \) is a primitive \( \text{mult}_N(S) \) root of unity, the matrix \( A \) is equivalent to \( M(S) \) up to some permutation, as desired. 

\[\square\]
Lemma 4.15. For a subset $S \subseteq [t]$ with $|S| = k$ and $M(S)$ (as defined in Definition 4.13) a $\text{fact}_N(S) \times \text{fact}_N(S)$ matrix as described above, we have

$$r_{M(S)} \left( \frac{\text{fact}_N(S)}{2^{e x^{0.41}}} \right) \leq (\text{fact}_N(S))^{3e}$$

as long as $k \geq x^{0.95}$

Proof. WLOG $S = \{1, 2, \ldots, k\}$. Consider the factorizations of $q_1 - 1, \ldots, q_k - 1$ into prime powers. For each prime power $p_i^{c_i} \leq x^{0.3}$, let $c_i(p_i^{c_i})$ be the number of indices $j$ for which $p_i^{c_i}$ appears (exactly) in the factorization of $q_j - 1$. Note that

$$(q_1 - 1) \cdots (q_k - 1) = \prod_t p_i^{c_i(t)}$$

where $t$ ranges over all prime powers at most $x^{0.3}$. Consider all prime powers $p_i^{c_i}$ for which $c_i(p_i^{c_i}) < x^{0.62}$.

$$\prod_{t, c(t) \leq x^{0.62}} t^{c(t)} \leq \left( \left( x^{0.3} x^{-0.62} \right)^{x^{0.3}} \right) \leq x^{x^{0.92}}$$

Now consider all prime powers $t_1, \ldots, t_n$ for which $c_i(t_i) \geq x^{0.62}$. Let $P = t_1^{c(t_1)} \cdots t_n^{c(t_n)}$ From the above we know that

$$P \geq \frac{\text{fact}_N(S)}{x^{x^{0.92}}} \geq (\text{fact}_N(S))^{(1-e)}$$

We will use the prime powers $t_i$ and Theorem 3.1 to show that $M(S)$ is not rigid. Note that we can associate each row and column of $M(S)$ to a $k$-tuple $(a_1, \ldots, a_k)$ where $a_i \in \mathbb{Z}_{q_i-1}$ as follows. First, it is clear that each row and column of $M(S)$ can be associated to a $k$-tuple $(z_1, \ldots, z_k) \in \mathbb{Z}_{q_1}^* \times \cdots \times \mathbb{Z}_{q_k}^*$. Now $\mathbb{Z}_{q_i}^*$ can be viewed as a cyclic group on $q_i - 1$ elements. This allows us to create a bijection between the rows and columns of $M(S)$ and elements of $\mathbb{Z}_{q_1-1} \times \cdots \times \mathbb{Z}_{q_k-1}$.

Also note that for a row indexed by $A = (a_1, \ldots, a_k)$ and a column indexed by $B = (b_1, \ldots, b_k)$, the entry $M(S)_{AB}$ is dependent only on $A + B$. We will now decompose $M(S)$ into several $P \times P$ submatrices. In particular, we can write $q_i - 1 = d_i T_i$ where $T_i$ is a product of some subset of $\{t_1, \ldots, t_n\}$ and $d_i$ is relatively prime to $T_i$. We have $T_1 T_2 \cdots T_k = P$. For each $A', B' \in \mathbb{Z}_{d_i} \times \cdots \times \mathbb{Z}_{d_k}$, we can construct a $P \times P$ submatrix $M(S, A', B')$ consisting of all entries $M(S)_{AB}$ of $M(S)$ such that $A \equiv A', B \equiv B'$ (where the equivalence is over $\mathbb{Z}_{d_i} \times \cdots \times \mathbb{Z}_{d_k}$). This gives us $d^2$ different submatrices where $d = d_1 \cdots d_k$. Naturally, we can associate each row and column of a submatrix $M(S, A', B')$ with an element of $\mathbb{Z}_{T_i} \times \cdots \times \mathbb{Z}_{T_k}$ such that for a row labeled $I$ and a column labeled $J$, the entry $M(S, A', B')_{IJ}$ only depends on $I + J$. In particular, this means that $X (M(S, A', B')) X$ is diagonal where $X = F_{T_1} \otimes \cdots \otimes F_{T_k}$. Now, using Lemma 4.8 we can rewrite

$$X = (F_{t_1} \otimes \cdots \otimes F_{t_1}) \otimes \cdots (F_{t_n} \otimes \cdots \otimes F_{t_n})$$

Since for $x$ sufficiently large, $c(t_i) \geq x^{0.62} \geq \frac{t_i^{(\log t_i)^2}}{e^t}$, we can use Lemma 4.10 and get that

$$r_X \left( \sum \frac{1}{c(t_i) x^{0.62}} \right) \leq P^e$$

14
Let \( E \) be the matrix of changes to reduce the rank of \( X \) according to the above. We have that \( E \) has at most \( P^e \) nonzero entries in each row and column and

\[
\text{rank}(X - E) \leq P \sum_{i=1}^{n} \left( \frac{1}{\frac{d}{\log\log n}} \right)
\]

We can write \( M(S) \) in block form as

\[
\begin{bmatrix}
M(S, A_1, B_1) & M(S, A_1, B_2) & \ldots & M(S, A_1, B_d) \\
M(S, A_2, B_1) & M(S, A_2, B_2) & \ldots & M(S, A_2, B_d) \\
\vdots & \vdots & \ddots & \vdots \\
M(S, A_d, B_1) & M(S, A_d, B_2) & \ldots & M(S, A_d, B_d)
\end{bmatrix}
\]

where \( A_1, \ldots, A_d \) and \( B_1, \ldots, B_d \) range over the elements of \( \mathbb{Z}_{d_1} \times \cdots \times \mathbb{Z}_{d_k} \). We can rearrange the above as

\[
\begin{bmatrix}
M(S, A_1, B_1) & \ldots & M(S, A_1, B_d) \\
\vdots & \ddots & \vdots \\
M(S, A_d, B_1) & \ldots & M(S, A_d, B_d)
\end{bmatrix}
\begin{bmatrix}
XD_{11}X & \ldots & XD_{1d}X \\
\vdots & \ddots & \vdots \\
XD_{d1}X & \ldots & XD_{dd}X
\end{bmatrix}
\]

where the \( D_{ij} \) are diagonal matrices. Now consider the matrix

\[
E(S) = \begin{bmatrix}
ED_{11}E & \ldots & ED_{1d}E \\
\vdots & \ddots & \vdots \\
ED_{d1}E & \ldots & ED_{dd}E
\end{bmatrix}
\]

We have

\[
M(S) - E(S) = \begin{bmatrix}
XD_{11}X - ED_{11}E & \ldots & XD_{1d}X - ED_{1d}E \\
\vdots & \ddots & \vdots \\
XD_{d1}X - ED_{d1}E & \ldots & XD_{dd}X - ED_{dd}E
\end{bmatrix}
\begin{bmatrix}
(X - E)D_{11}E & \ldots & (X - E)D_{1d}E \\
\vdots & \ddots & \vdots \\
(X - E)D_{d1}E & \ldots & (X - E)D_{dd}E
\end{bmatrix}
\]

In the above expression, each of the two terms has rank at most

\[
dP \sum_{i=1}^{n} \left( \frac{1}{\frac{d}{\log\log n}} \right) = \text{fact}_N(S) \sum_{i=1}^{n} \left( \frac{1}{\frac{d}{\log\log n}} \right) \leq \frac{1}{2} \left( \text{fact}_N(S) \right)
\]

Note that when computing the rank, we only multiply by \( d \) (and not \( d^2 \)) because the small blocks are all multiplied by the same low rank matrix on either the left or right. The number of nonzero entries in each row and column of \( E(S) \) is at most \( P^d d = \frac{\text{fact}_N(S)}{2^e} \). Since \( P \geq (\text{fact}_N(S))^{1-e} \), we conclude

\[
\tau_{M(S)} \left( \frac{\text{fact}_N(S)}{2^e} \right) \leq (\text{fact}_N(S))^{3e}
\]

We are now ready to complete the analysis of the non-rigidity of the Fourier transform matrix \( F_N \).
Proof of Theorem \[4.7\] Set the threshold \(k_0 = l \left(1 - \frac{4}{2^{e^{0.001}}} \right)\). The sets \(T_S\), as \(S\) ranges over all subsets of \([l]\), form a partition of \([N] \times [N]\). For each \(S \subset [l]\) with \(|S| \geq k_0\), we will divide \(T_S\) into \(\text{fact}_N(S) \times \text{fact}_N(S)\) submatrices using Lemma \[4.14\] and change entries to reduce the rank of every submatrix according to Lemma \[4.15\]. We will not touch the entries in sets \(T\) submatrices using Lemma \[4.14\] and change entries to reduce the rank of every submatrix according to Lemma \[4.14\].

The first ingredient will be a stronger form of Lemma \[4.3\]. Recall that a prime Fourier matrices are not rigid. In this section, we will bootstrap the results from Section 4 to show that in fact, all sufficiently large Fourier matrices are not Valiant-rigid. In the previous section, we showed that there exists an infinite set of Fourier matrices that are not Valiant-rigid. We now estimate the rank of \(M\) and then the maximum number of entries changed in any row or column.

Let \(m = l - k_0 = \frac{4}{2^{e^{0.001}}} l\). Note since \(l \geq x^{0.999}\), \(m \geq e^{4x^{0.005}}\). We remove all rows and columns corresponding to integers divisible by at least \(m\) of the primes \(q_1, \ldots, q_l\). Since \(l \leq x^{0.993}\), the number of rows and columns removed is at most

\[
N \left( \sum_{S \subset [l], |S|=k} \prod_{i \in S} \frac{1}{q_i} \right) \leq \frac{N}{x^{0.999} \frac{m}{2}} \leq \frac{N}{x^{0.003} m}
\]

The remaining entries must be subdivided into matrices of the form \(M(S)\) for various subsets \(S \subset [l]\), \(|S| \geq k_0\). Say \(q_1 < q_2 < \cdots < q_l\). The number of such submatrices is at most

\[
\frac{N^2}{((q_1 - 1) \cdots (q_{k_0} - 1))} \leq \left( \frac{q_{k_0+1} \cdots q_l}{(q_1 - 1) \cdots (q_{k_0} - 1)} \right)^2 \leq 3(q_{k_0+1} \cdots q_l)^2 \leq 3x^{2m}
\]

Each one of the submatrices has rank at most

\[
\frac{N}{2^{e^{x^{0.001}}}}
\]

so in total the rank is at most

\[
\frac{N}{2^{e^{x^{0.002}}}}
\]

Combining the two parts we easily get

\[
\text{rank}(M') \leq \frac{N}{2^{e^{x^{0.001}}}}
\]

Now we bound the number of entries changed. The number of entries changed in each row or column is at most

\[
\frac{N}{((q_1 - 1) \cdots (q_{k_0} - 1))} N^{3e} \leq (q_{k_0+1} \cdots q_l) \left( \frac{q_1 \cdots q_{k_0}}{(q_1 - 1) \cdots (q_{k_0} - 1)} \right) N^{3e} \leq 3N^{3e+1.1} \leq N^{4e}
\]

As \(2^{e^{x^{0.001}}} \geq 2^{e^{4(\log N)^{0.0005}}}\) for sufficiently large \(x\), we conclude

\[
\tau_{FN} \left( \frac{N}{2^{e^{4(\log N)^{0.0005}}}} \right) \leq N^{4e}
\]

\[\square\]

5 Non-rigidity of All Fourier Matrices

In the previous section, we showed that there exists an infinite set of Fourier matrices that are not Valiant-rigid. In this section, we will bootstrap the results from Section 4 to show that in fact, all sufficiently large Fourier matrices are not rigid.

The first ingredient will be a stronger form of Lemma \[4.3\]. Recall that a prime \(q\) is defined to be \(x\)-good if \(x^{0.999} \leq q \leq x\) and all prime powers dividing \(q - 1\) are at most \(x^{0.5}\) and that an integer \(N\) is defined to be \((l, x)\)-factorable if it can be written as the product of \(l\) distinct \(x\)-good primes.
Lemma 5.1. For all sufficiently large integers $K$, there exist $l, x, N$ such that $x^{0.99} \leq l \leq x^{0.993}$, $N$ is $(l, x)$-factorable, and $K < N < K(\log K)^2$.

Proof. Call an $N$ well-factorable if it is $(l, x)$-factorable for some $x$ and $x^{0.99} \leq l \leq x^{0.993}$. Let $N_0$ be the largest integer that is well-factorable with $N_0 \leq K$. Say $N_0$ is $(l, x)$-factorable.

We have $N_0 = q_1 \ldots q_1$ where $q_1, \ldots, q_1$ are distinct, $x$-good primes. If $l < \lceil x^{0.993} \rceil$ then by Lemma 4.3 we can find another $x$-good prime $q_{l+1}$. We can then replace $N_0$ with $q_{l+1}N_0$. $q_{l+1}N_0 > K$ by the maximality of $N_0$ and also $q_{l+1}N_0 \leq N_0x \leq N_0(\log N_0)^2$ so $q_{l+1}N_0$ satisfies the desired properties.

We now consider the case where $l = \lceil x^{0.993} \rceil$. First, if $q_1, \ldots, q_1$ are not the $l$ largest $x$-good primes then we can replace one of them say $q_1$ with $q_1' > q_1$. The number $N' = q_1'q_2 \ldots q_1$ is well-factorable and between $N_0$ and $N_0x^{0.001}$. Using the maximality of $N_0$, we deduce that $N'$ must be in the desired range.

On the other hand if $q_1, \ldots, q_1$ are the $l$ largest $x$-good primes, we know they are actually all between $x^{0.9995}$ and $x$. This is because by Lemma 4.3 there are more than $x^{0.9995} + l$ distinct $x$-good primes. Let $C$ be the constant in Theorem 4.5 and let $x' = x(\log x)^C + 1$. The above implies that $q_1, \ldots, q_1$ are $x'$-good and clearly $x^{0.99} \leq l \leq x^{0.993}$. By Lemma 4.3 there are more than $x$ distinct $x'$-good primes so there exists some $q > x$ that is $x'$-good. The product $N' = q_1 \ldots q_1q$ is well-factorable and larger than $N_0$ so $N' > K$. Also $N' \leq N_0x^{0.001}(\log x)^{C+1} < K(\log K)^2$ so $N'$ is in the desired range.

Also note that as a consequence of Theorem 4.7 we have:

Lemma 5.2. Let $0 < \epsilon < 0.1$ be fixed, $x$ sufficiently large, and $N_0$ a $(l, x)$-factorable integer with $x^{0.99} \leq l \leq x^{0.993}$. If \( \frac{N_0}{(\log N_0)^{\epsilon}} \leq N \leq \frac{N_0}{2} \) then any $N \times N$ adjusted-circulant matrix $M$ satisfies

\[
r_M \left( \frac{N}{2^{x(\log N)^{\epsilon}} \nonumber} \right) \leq N^{9\epsilon}
\]

Proof. By Claim 2.16, Lemma 2.18 and Theorem 4.7 any adjusted-circulant matrix $M_0$ of size $N_0$ satisfies

\[
r_{M_0} \left( \frac{2N_0}{2^{x(\log N_0)^{\epsilon}}} \right) \leq N_0^{8\epsilon}
\]

Any adjusted-circulant matrix of size at most $\frac{N_0}{2}$ can be embedded (in the upper left corner) of an adjusted-circulant matrix of size $N_0$ so we have the same inequality for the matrix $M$. Rewriting the bounds in terms of $N$, we get the desired.

We now have all of the parts to prove that all Fourier matrices are highly non-rigid.

Theorem 5.3. For any fixed $0 < \epsilon < 0.1$ and $N$ sufficiently large,

\[
r_{F_N} \left( \frac{N}{2^{x(\log N)^{\epsilon}}} \right) \leq N^{9\epsilon}
\]

Proof. By Lemma 5.1, we can find an integer $N_0$ such that $2N < N_0 < 2N(\log 2N)^2$ and $N_0$ is $(l, x)$-factorable for some $x$ and $x^{0.99} \leq l \leq x^{0.993}$. We have \( \frac{N_0}{(\log N_0)^{\epsilon}} \leq N \leq \frac{N_0}{2} \). Thus, by Lemma 5.2 all $N \times N$ adjusted-circulant matrices satisfy

\[
r_M \left( \frac{N}{2^{x(\log N)^{\epsilon}}} \right) \leq N^{9\epsilon}
\]

Note that by Claim 2.19 the rows and columns of $F_N$ can be rescaled to obtain an adjusted-circulant matrix so $F_N$ also satisfies the above inequality, completing the proof.

We can now conclude that all adjusted-circulant and Hankel matrices are not Valiant-rigid.
Corollary 5.4. Let $0 < \epsilon < 0.1$ be fixed. For all sufficiently large $N$, if $M$ is an $N \times N$ adjusted-circulant (or Hankel) matrix

$$r_M \left( \frac{N}{2^{e^4 (\log N)^{0.0004}}} \right) \leq N^{20\epsilon}$$

Proof. The result for circulant matrices follows immediately from the above and Lemma 2.18. For Hankel matrices, note that it is possible to embed any Hankel matrix of size $N$ into the top left corner of a circulant matrix of size $2N$. 

6 Non-rigidity of Group Algebra Matrices for Abelian Groups

Using the results from the previous section, we can show that group algebra matrices for any abelian group are not Valiant-rigid.

Theorem 6.1. Let $0 < \epsilon < 0.1$ be fixed. Let $G$ be an abelian group and $f : G \to \mathbb{C}$ be a function. Let $M = M_G(f)$ be the adjusted group algebra matrix. If $|G|$ is sufficiently large then

$$r_M \left( \frac{2|G|}{2^{e^4 (\log (|G|))^{0.0004}}} \right) \leq |G|^{26\epsilon}$$

Proof. By the fundamental theorem of finite abelian groups, we can write $G = \mathbb{Z}_{n_1} \oplus \cdots \oplus \mathbb{Z}_{n_a}$. In light of Lemma 2.18 it suffices to bound the rigidity of $F = F_{n_1} \otimes \cdots \otimes F_{n_a}$.

WLOG, $n_1 \leq n_2 \leq \cdots \leq n_a$. We will choose $k$ to be a fixed, sufficiently large positive integer. By Theorem 5.3 we can ensure that for $N > k$

$$r_{F_N} \left( \frac{N}{2^{e^4 (\log N)^{0.0004}}} \right) \leq N^{9\epsilon}$$

Consider the ranges $I_1 = [k, k^2], I_2 = [k^2, k^4], \ldots, I_j = [k^{2^{j-1}}, k^{2^j}]$ and so on. Let $S_j$ be a multiset defined by $S_j = I_j \cap \{n_1, \ldots, n_a\}$. Fix a $j$ and say the elements of $S_j$ are $x_1 \leq \cdots \leq x_b$. By Theorem 5.3 for each $x_i$, there are matrices $E_{x_i}$ and $A_{x_i}$ such that $F_{x_i} = A_{x_i} + E_{x_i}, E_{x_i}$ has at most $x_i^{9\epsilon}$ nonzero entries in each row and column, and

$$\text{rank}(A_{x_i}) \leq \frac{x_i}{2^{e^4 (\log x_i)^{0.0004}}}$$

Now we can write

$$M_j = F_{x_1} \otimes \cdots \otimes F_{x_b} = (A_{x_1} + E_{x_1}) \otimes \cdots \otimes (A_{x_b} + E_{x_b}) = \sum_{S \subseteq \{b\}} \left( \bigotimes_{i \in S} A_{x_i} \right) \otimes \left( \bigotimes_{i' \not\in S} E_{x'_i} \right)$$

$$= \sum_{S \subseteq \{b\}, |S| \geq cb} \left( \bigotimes_{i \in S} A_{x_i} \right) \otimes \left( \bigotimes_{i' \not\in S} E_{x'_i} \right) + \sum_{S \subseteq \{b\}, |S| < cb} \left( \bigotimes_{i \in S} A_{x_i} \right) \otimes \left( \bigotimes_{i' \not\in S} E_{x'_i} \right)$$

Let the first term above be $N_1$ and the second term be $N_2$. We will bound the rank of $N_1$ and the number of nonzero entries in each row and column of $N_2$. Note that by grouping the terms in the sum for $N_1$ we can write it in the form

$$\sum_{S \subseteq \{b\}, |S| = [cb]} \bigotimes_{i \in S} A_{x_i} \otimes E_S$$

where for each $S$, $E_S$ is some matrix. This implies that

$$\text{rank}(N_1) \leq \left( \frac{b}{[cb]} \right) \frac{x_1 \cdots x_b}{(2^{e^4 (\log x_1)^{0.0004}})^{|cb|}} \leq \frac{b^{|cb|}}{([cb])^{2^{e^4 (\log x_1)^{0.0004}}}} \frac{x_1 \cdots x_b}{(2^{e^4 (\log x_1)^{0.0004}})^{|cb|}} = x_1 \cdots x_b \left( \frac{3}{(e^{2^{e^4 (\log x_1)^{0.0004}}})^{[cb]}} \right)$$
As long as $k$ is sufficiently large, we have

$$
\text{rank}(N_1) \leq x_1 \ldots x_b \left( \frac{3}{2^{e^4(\log x_1)^{0.005}}} \right)^{\lfloor eb \rfloor} \leq x_1 \ldots x_b \left( \frac{1}{2^{e^4(\log x_1)^{0.005}}} \right)^{\lfloor eb \rfloor} \leq x_1 \ldots x_b
$$

where in the last step we used the fact that $x_i \leq x_1^2$ for all $i$. The number of nonzero entries in each row or column of $N_2$ is at most

$$
2^b x_b \ldots x_{b-|c|+1} (x_{b-|c|} \ldots x_1)^{9e} = 2^b (x_1 \ldots x_b)^{9e} (x_b \ldots x_{b-|c|+1})^{1-9e} \leq (x_1 \ldots x_b)^{12e}
$$

Note in the last step above, we used the fact that $x_i \leq x_1^2$.

For each integer $c$ between 2 and $k$, let $n_c$ be the number of copies of $c$ in the set $\{n_1, \ldots, n_a\}$. If $n_c \geq \frac{k^2(\log k)^2}{c^4}$, then by Theorem 3.1 if we define $A_c = F_c \otimes \cdots \otimes F_c$ then

$$
r_{A_c} \left( c^{n_c(1 - \frac{4}{k^2 \log k})} \right) \leq c^{n_c}
$$

Let $L = \left[ 2 \log \log |G| \right]$ and ensure that $|G|$ is sufficiently large so that $L > k$. Let $T$ be the set of integers $c$ between 2 and $k$ such that $c^{n_c} \geq |G|^\frac{12}{13}$ (note that as long as $|G|$ is sufficiently large, all elements of $T$ must satisfy $n_c \geq \frac{k^2(\log k)^2}{c^4}$). Let $R$ be the set of indices $j$ for which $\prod_{x \in S_j} x \geq |G|^\frac{12}{13}$. Since $S_j$ is clearly empty for $j \geq L$, the matrix $F$ can be written as

$$
F = \left( \bigotimes_{2 \leq c \leq k} \left( \frac{F_c \otimes \cdots \otimes F_c}{n_c} \right) \right) \otimes \left( \bigotimes_{j \leq L} M_j \right)
$$

Define

$$
B = \left( \bigotimes_{c \in T} \left( \frac{F_c \otimes \cdots \otimes F_c}{n_c} \right) \right) \otimes \left( \bigotimes_{j \not \in R} M_j \right)
$$

Note that the size of $B$ is at most $(|G|^\frac{12}{13})^{k+L} \leq |G|^\frac{12}{13}$. Also $F = B \otimes D$ where

$$
D = \left( \bigotimes_{c \in T} \left( \frac{F_c \otimes \cdots \otimes F_c}{n_c} \right) \right) \otimes \left( \bigotimes_{j \in R} M_j \right)
$$

For any rank $r$, $r_M(|B|r) \leq |B|r_D(r)$. Applying Lemma 4.9 iteratively, we get

$$
r_D \left( \left| \frac{|G|}{|B|} \right| \left( \sum_{c \in T} \frac{1}{c^{k^4 \log k}} + \sum_{j \in R} \frac{1}{2^{e^4(\log \prod_{x \in S_j} x)^{0.005}}} \right) \right) \leq \left( \left| \frac{|G|}{|B|} \right| \right)^{12e}
$$

Note that

$$
\left( \sum_{c \in T} \frac{1}{c^{k^4 \log k}} + \sum_{j \in R} 2^{e^4(\log \prod_{x \in S_j} x)^{0.005}} \right) \leq \frac{k}{|G|^{2k^4 \log k}} + \frac{L}{2^{e^4(\log |G|)^{0.005}}} \leq \frac{1}{2^{e^4(\log |G|)^{0.005}}}
$$

Overall, we conclude

$$
r_F \left( \frac{|G|}{2^{e^4(\log |G|)^{0.005}}} \right) \leq |B| \left( \left| \frac{|G|}{|B|} \right| \right)^{12e} \leq |G|^{1.13e}
$$

Since $FMF$ is diagonal, Lemma 2.18 gives the desired.
7 Final Remarks

7.1 Rigidity over Fields and Extensions

The proofs in the previous sections actually tell us slightly more about the non-rigidity of Fourier and circulant matrices than what is stated in our results. Firstly, our proof of Theorem 5.3 easily generalizes to any field where the necessary roots of unity (for the Fourier matrix and the generalized Hadamard matrices we embed into it) exist. Over a finite field of characteristic \( p \), it is not difficult to adapt our proof in order to avoid using roots of unity of order \( p \) (as \( x^p - 1 = (x - 1)^p \)). Also note that in our proof of non-rigidity for \( F_N \) (the \( N \times N \) Fourier matrix), the changes we make to the entries all live in a number field of dimension polynomial in \( N \). Combining this insight with Lemma 2.18 gives us:

**Corollary 7.1.** Let \( 0 < \epsilon < 0.1 \) be fixed. Let \( M \) be an \( N \times N \) circulant matrix with entries in a field \( F \). For \( N \) sufficiently large, there exists an algebraic extension of \( F \) with dimension polynomial in \( N \), say \( E \), such that over \( E \)

\[
\tau_M \left( \frac{N}{2^{\epsilon^4(\log N)^{1.003}}} \right) \leq N^{20\epsilon}
\]

In particular, \( M \) is not rigid over the algebraic closure of \( F \).

In fact, we get a slightly stronger result, that for any circulant matrix \( M \), the locations of the entries that need to be changed is fixed and the changes are fixed linear combinations of the entries. This is important because when following Valiant’s graph-theoretic approach for proving circuit lower bounds in [Val77], this slightly weaker notion of rigidity is exactly what is necessary to prove lower bounds. Our result is thus a strong indication that Valiant’s overall graph-theoretic approach cannot be used to prove circuit lower bounds for computing convolutions (which correspond to circulant matrices).

Corollary 7.1 naturally raises the question of whether matrices can be rigid over some small field \( F \) but non-rigid over some extension. While it seems unlikely to expect the rigidity over any field \( F \) to equal the rigidity over any extension, we think it is an interesting open question to consider when it might be possible to relate (asymptotically) the rigidity of a family of matrices over \( F \) to their rigidity over various extensions of \( F \).

7.2 Group Algebra Matrices

Theorem 6.1 naturally raises the question of what happens when \( G \) is a non-abelian group. When \( G \) is non-abelian, it is no longer possible to diagonalize the matrix \( M_G(f) \) but there is a change of basis matrix \( A \) such that \( AM_G(f)A^* \) is block-diagonal where the diagonal blocks correspond to the irreducible representations of \( G \). When all of the irreducible representations of \( G \) are small, it may be possible to use similar techniques to the ones used here. On the other hand, this suggests that perhaps \( M_G(f) \) is a candidate for rigidity when all irreducible representations of \( G \) are large (for instance quasi-random groups [Gow08]).
