1. Introduction

During 1955-56 Harish-Chandra published three papers in the American Journal of Mathematics devoted to understanding the theory of representations of a real semisimple Lie group, which are also (infinitesimally) highest weight modules [27]. These modules were constructed both infinitesimally and globally, the global modules realized as spaces of sections of certain holomorphic vector bundles on the associated symmetric space, which is hermitian symmetric. He constructed the matrix element defined by the highest weight vector, and verified its square integrability under suitable conditions. Under these conditions, the representations were in the discrete series and he obtained formulae for their formal degree and character, which showed a strong resemblance to the Weyl formulae in the finite dimensional case. These calculations convinced him of the structure of the discrete series in the general case, although he was still years away from resolving this puzzle completely.

The purpose of this paper is to generalize some aspects of this theory to the supersymmetric situation.

In the literature, several authors have discussed unitarizable infinitesimal Harish-Chandra modules, see for example [29, 16, 22] and Refs. within. In [29] Jakobsen classifies the unitarizable highest weight modules for Lie superalgebras, while Furutsu and Nishiyama in [22] focus on the case \( su(p, q|n) \). A global realization of such modules for the conformal supergroup appears in [15] and in full generality later on in [1], where the author establishes an equivalence of categories between certain Harish-Chandra modules and the category of smooth Frechét representations of the supergroup whose module of \( K \)-finite vectors is Harish-Chandra. Our Theorem [12] can be read as an explicit realization of such equivalence. These representations appear classically in the space of holomorphic sections on hermitian spaces. An infinitesimal realization of such spaces in the supersetting is due first to Serganova in [43] and later on to Borthwick et al. in [6], though they do not construct the super Harish-Chandra modules associated with them.
In the present work, we start by examining the infinitesimal setting, that is the Harish-Chandra highest weight supermodules over the complex field for \( g \), a complex basic Lie superalgebra, \( g \neq A(n,n) \), \( g_1 \neq 0 \). Let \( g \) be a real form of \( g \) and let \( g = \mathfrak{t} \oplus \mathfrak{p} \), be the complex super Cartan decomposition (\( \mathfrak{t} = \mathfrak{t}_0 \) the complexification of the maximal compact subalgebra \( \mathfrak{h}_r \) of \( \mathfrak{g}_r \)). Assume \( \mathfrak{h}_r \subset \mathfrak{t}_r \), that is \( \text{rk}(\mathfrak{t}) = \text{rk}(g) \), where \( \mathfrak{h} \), the complexification of \( \mathfrak{h}_r \), is a Cartan subalgebra (CSA) of both \( \mathfrak{t} \) and \( g \).

The main results for the infinitesimal theory are Theorems 2.9 and 2.12, that we summarize here.

**Theorem 1.1.** Let \( \lambda \in \mathfrak{h}^* \), \( \lambda(\mathfrak{h}_\alpha) \in \mathbb{Z}_{\geq 0} \) for all compact roots \( \alpha \). Let \( U^\lambda = \mathcal{U}(g) \otimes \mathcal{U}(q) \mathcal{F} \) (\( F \) the finite dimensional representation of \( \mathfrak{t} \) associated with \( \lambda \), \( q = \mathfrak{t} \oplus \mathfrak{p}^+ \)). Then

1. \( U^\lambda \) is the universal Harish-Chandra supermodule of highest weight \( \lambda \).
2. \( U^\lambda \) has a unique irreducible quotient, which is the unique (up to isomorphism) irreducible highest weight Harish-Chandra supermodule with highest weight \( \lambda \).
3. If \( (\lambda + \rho)(\mathfrak{h}_r) \leq 0 \) for all \( \gamma \in P_+ \) and \( < 0 \) for \( \gamma \) isotropic, then \( U^\lambda \) is irreducible.

The construction of \( U^\lambda \) is based on the existence of admissible systems for \( g \). These are positive systems such that the adjoint representation of \( \mathfrak{t} \) on \( \mathfrak{p} \) stabilizes \( \mathfrak{p}^\pm \), the sum of the positive (negative) non compact root spaces. In [13] is proven the existence of such systems using diagrammatic methods; here we exhibit them and take a more conceptual approach (Theorem 2.6). The existence of admissible systems is instrumental to provide an invariant complex structure on \( g_r/\mathfrak{t}_r \), which is the infinitesimal counterpart of the complex structure on the homogeneous superspace \( G_r/K_r \) \( (g_r = \text{Lie}(G_r), \mathfrak{t}_r = \text{Lie}(\mathfrak{t}_r)) \), that we will use to build the global Harish-Chandra representations. In the end of this part (Sec. 2.5), we obtain a character formula for the universal Harish-Chandra supermodule.

In the second part of the paper we proceed to study the geometric realization of the Harish-Chandra representation on the superspace of holomorphic sections of a vector bundle defined on the symmetric superspace \( G_r/K_r \). We construct the infinite dimensional Harish-Chandra super representations of a real form \( G_r \) of a simple complex Lie supergroup \( G \), whose infinitesimal version are the supermodules constructed in the first part of the paper. We first consider the Fréchet superspace of global sections of a (complex) line bundle \( L^x \) on the quotient \( G/B^+ \), associated with the infinitesimal character \( \lambda \) (see Theorem 1.1), where \( B^+ \) is a Borel subsupergroup of \( G \) associated with an admissible system \( P \). In order to prove that \( L^x(G,B^+) \neq \{0\} \), we use the existence of a global section of the projection \( N^-B^+ \rightarrow N^-B^+/B^+ \) which in turn ensures the existence of an isomorphism \( \mathcal{O}(N^-) \rightarrow L^x(N^-B^+) : f \mapsto f^- \). Exactly as in the Harish-Chandra’s theory, under generic conditions, we are able to go, from line bundles on \( G/B^+ \), to vector bundles over \( G_r/K_r \). We also obtain the Harish-Chandra decomposition \( P^-K P^+ \subset G \), \( \mathfrak{p}^\pm = \text{Lie}(P^\pm) \); however, while in the ordinary setting \( P^\pm \) are abelian subgroups, in the supersetting this is no longer true. This is due to the fact that the superalgebras \( \mathfrak{p}^\pm \) are not in general abelian. Nevertheless, we are able to give a thorough description of such representations. The main results for this part are in Theorems 4.27 4.32 and Corollary 4.28 that we summarize here:

**Theorem 1.2.** Let \( \chi \) be a character of \( B^+ \subset G \) corresponding to the infinitesimal character \( \lambda \in \mathfrak{h}^* \). Let \( L^x(G,B^+) := \{ f : G,B^+ \rightarrow \mathbb{C}[t] \mid f_{|r}(gb) = \chi_r(b)^{-1}f_{|r}(g) \} \) and assume its reduced part \( L^x(G_r,B^+) := \{ f \mid f \in L^x(G_r,B^+) \} \neq 0 \). Let \( \ell \) denote the natural left action of \( \mathcal{U}(g) \) on the sections in \( L^x(G_r,B^+) \). Then:
(1) \( L^\lambda(G_rB^+) \) contains an element \( \psi \) which is an analytic continuation of \( 1^\sim \) (the polynomial section corresponding to 1);

(2) \( F^{11} := \ell(\mathcal{U}(g))\psi \subset L^\lambda(G_rB^+) \) is a Fréchet \( G_r \)-supermodule, \( K_r \)-finite and with \( K_r \)-finite part \( \ell(\mathcal{U}(g))\psi = \mathcal{P}_\lambda^\sim \) (the polynomial sections).

(3) the \( K_r \)-finite part \( \mathcal{P}_\lambda^\sim \) is isomorphic to \( \pi_\lambda \) the irreducible representation with lowest weight \( -\lambda \). In particular \( \lambda(H_\alpha) \in \mathbb{Z}_{\geq 0} \) for all compact positive roots \( \alpha \).

(4) \( \ell(\mathcal{U}(g))\psi \) is the irreducible Harish-Chandra supermodule with highest weight \( -\lambda \) with respect to the positive system \( -P \).

Vice-versa, if the center of \( \mathfrak{k} \) has positive dimension, and \( \lambda \in \mathfrak{h}^* \) is integral, \( K \)-integrable and \( \lambda(H_\alpha) \geq 0 \) for \( \alpha \) compact positive root, then \( L^\lambda(G_rB^+) \neq 0 \).

Acknowledgements. We wish to thank Professor V. Serganova for many helpful comments on the infinitesimal theory. We also thank the anonymous Referee for his invaluable work, which has greatly helped us to improve this paper.

2. The infinitesimal theory

In this section we start with the discussion of the infinitesimal theory, namely the representation of the pair \((g_r, \mathfrak{t}_r)\), where \( g_r \) is a real basic Lie superalgebra and \( \mathfrak{t}_r \) the maximal compact subalgebra of its even part.

2.1. Summary of results for basic Lie superalgebras. Assume \( g \) to be basic classical, \( g \neq A(n,n), g_1 \neq 0 \), i.e. (see [31] Prop. 1.1):

(1) \( A(m,n) \) with \( m \neq n \), \( B(m,n), C(n), D(m,n), D(2,1; \alpha), F(4), G(3) \)

Let \( \mathfrak{h} = \mathfrak{h}_0 \) be a Cartan subalgebra of \( g_0 \) and let \( g = \mathfrak{h} \oplus \sum_{\alpha \in \Delta} g_\alpha \) be the root space decomposition of \( g \).

\( \Delta_0 \) and \( \Delta_1 \) denote the set of even and odd roots respectively, where we say that a root \( \alpha \) is even if \( g_\alpha \cap g_0 \neq 0 \) and similarly for the odd case.

The following proposition shows that many properties of the Cartan-Killing theory extend to the basic classical Lie superalgebras.

Proposition 2.1 ([31] Prop. 1.3, [30] Prop. 2.5.5). A basic classical Lie superalgebra in list [3] satisfies the following properties:

(1) \( \dim g_\alpha = 1 \), for all \( \alpha \in \Delta \).

(2) \([g_\alpha, g_\beta] = 0 \) if and only if \( \alpha, \beta \in \Delta, \alpha + \beta \notin \Delta \).

(3) \([g_\alpha, g_\beta] = g_{\alpha+\beta} \) if \( \alpha, \beta, \alpha + \beta \in \Delta \).

(4) \([g_\alpha, g_\beta] = 0 \) for \( \alpha \neq -\beta \). The form \((,\)\) determines a non degenerate pairing of \( g_\alpha \) with \( g_{-\alpha} \) and \((,\)|\(\mathfrak{h} \times \mathfrak{h}\) is non degenerate.

(5) \([e_\alpha, e_{-\alpha}] = (e_{\alpha}, e_{-\alpha})h_\alpha \), where \( h_\alpha \) is defined by \((h_\alpha, h) = \alpha(h)\) and \( e_{\pm \alpha} \in g_{\pm \alpha} \).

(6) The bilinear form of \( \mathfrak{h}^* \) defined by \((\lambda, \mu) = (h_\lambda, h_\mu)\) is non degenerate and \( W \)-invariant, where \( W \) is the Weyl group of \( g_0 \).

(7) \( k\alpha \in \Delta \) for \( \alpha \neq 0 \) and \( k \neq \pm 1 \) if and only if \( \alpha \in \Delta_1 \) and \( (\alpha, \alpha) \neq 0 \). In this case \( k = \pm 2 \).
The last point characterizes a root for which \((\alpha, \alpha) = 0\): it is an odd root \(\alpha\) such that \(2\alpha\) is not a root. Such roots are called isotropic roots. Notice that, for example, in \(\mathfrak{sl}(m|n)\) all odd roots are isotropic.

**Definition 2.2.** Let the notation and the hypotheses be as above. We define a Borel subsuperalgebra, as a subsuperalgebra \(\mathfrak{b} \subset \mathfrak{g}\), such that:

- \(\mathfrak{b}_0\) is a Borel subalgebra of \(\mathfrak{g}_0\);
- \(\mathfrak{b} = \mathfrak{h} \oplus \mathfrak{n}^+\), where \(\mathfrak{n}^+\) is a nilpotent ideal of \(\mathfrak{b}\),

and \(\mathfrak{b}\) is maximal with respect to these properties (see [40] pg 26 for more details).

Let us fix a Borel subsuperalgebra \(\mathfrak{b}\). We say that a root \(\alpha\) is positive if \(\mathfrak{g}_\alpha \cap \mathfrak{n}^+ \neq \{0\}\), we say that it is negative if \(\mathfrak{g}_\alpha \cap \mathfrak{n}^+ = \{0\}\). \(\mathfrak{n}^+\) is the span of the positive root spaces and we define \(\mathfrak{n}^-\) as the span of the negative ones. We define the positive system \(\mathcal{P}\) as the set of positive roots. We say that a positive root is simple if it is indecomposable, that is, if we cannot write it as a sum of two positive roots. Let \(\Pi = \{\alpha_1, \ldots, \alpha_r\}\) be the set of simple roots, we also call \(\Pi\) a fundamental system.

We have the following result (see [31] Prop. 1.5).

**Proposition 2.3.** Let \(\mathfrak{g}\) be a basic classical Lie superalgebra as above. Fix a Borel subsuperalgebra and let the notation be as above. Then

1. The simple roots \(\alpha_1, \ldots, \alpha_r\) are linearly independent.
2. We may choose elements \(e_i \in \mathfrak{g}_{\alpha_i}\) and \(f_i \in \mathfrak{g}_{-\alpha_i}\) and \(h_i \in \mathfrak{h}\) such that \(\{e_i, f_i, h_i\}_{i \in I}\) is the system of generators of \(\mathfrak{g}\) satisfying the relations:
   \[
   [e_i, f_j] = \delta_{ij}h_i, \quad [h_i, h_j] = 0, \quad [h_i, e_j] = a_{ij}e_j, \quad [h_i, f_j] = -a_{ij}f_j,
   \]
   for a suitable non singular integral matrix \(A = (a_{ij})_{i,j \in I}\) (the Cartan matrix of \(\mathfrak{g}\)).
3. \(\mathfrak{n}^\pm\) are generated by the \(e_i\)’s and \(f_i\)’s respectively.
4. \(\Delta = \mathcal{P} \bigcup -\mathcal{P}\) and \(\mathcal{P}\) consists of the roots which are integral positive linear combinations of simple roots.

As in the case with the ordinary Lie algebras, in the theory of finite dimensional representations of \(\mathfrak{g}\), a fundamental role is played by the highest weight modules. These are defined with respect to the choice of a CSA \(\mathfrak{h}\) of \(\mathfrak{g}\) and a positive system \(\mathcal{P}\) of roots of \((\mathfrak{g}, \mathfrak{h})\). They are parametrized by their highest weights. The universal highest weight modules are known as super Verma modules and are infinite dimensional. The irreducible highest weight modules are uniquely determined by their highest weights and are the unique irreducible quotients of the super Verma modules. The irreducible modules are finite dimensional if and only if the highest weight is dominant integral and it satisfies a condition which can be expressed in terms of all of the Borel subsuperalgebras containing \(\mathfrak{h}\) (in the ordinary theory they are all conjugate, while in the super theory they are not). Furthermore, one obtains all irreducible finite dimensional representations of \(\mathfrak{g}\) in this manner (see Refs. [30, 31, 40]).

Our goal is to describe the infinite dimensional highest weight supermodules, which are also \(k\)finite, in the case \(\text{rk}(\mathfrak{k}) = \text{rk}(\mathfrak{g}_0)\), so that the CSA \(\mathfrak{h}\) of \(\mathfrak{k}\) is also a CSA of \(\mathfrak{g}_0^s\), the semisimple part of \(\mathfrak{g}_0\) (see Sec. 2.2 for the definition of the compact subalgebra \(\mathfrak{k}_r\) and its complexification \(\mathfrak{k}\)). It is important to remark that in the ordinary setting, not every choice of positive system leads to infinite dimensional highest weight \(k\)finite \(\mathfrak{g}\) representations. The
positive systems with this property are called *admissible* and they are characterized by the presence of *totally positive roots*, that is positive non compact roots, which stay positive under the adjoint action of $\mathfrak{k}$, (see Ref. [27]).

### 2.2. Admissible Systems.

Let $\mathfrak{g}$ be a complex basic classical Lie superalgebra, $\mathfrak{g} \neq A(n, n)$ and $\mathfrak{g}_r$ a real form of $\mathfrak{g}$. We have the ordinary Cartan decomposition:

\begin{equation}
\mathfrak{g}_{r,0}^{ss} = \mathfrak{k}_{r,0}^{ss} \oplus \mathfrak{p}_{r,0}, \quad \mathfrak{g}_0^{ss} = \mathfrak{k}_0^{ss} \oplus \mathfrak{p}_0, \quad \mathfrak{p}_{r,0} = (\mathfrak{p}_{r,0}^{ss})^\perp
\end{equation}

where we drop the index $r$ to mean the complexification.

The ordinary real Lie algebra $\mathfrak{g}_{r,0}$ may not be semisimple; this happens for the type I Lie superalgebras, in which case $\mathfrak{g}_{r,0}$ has a one-dimensional center. We define $\mathfrak{k}_r$ as $\mathfrak{k}_{r,0}^{ss}$, when $\mathfrak{g}_{r,0} = \mathfrak{g}_r$, that is when $\mathfrak{g}_{r,0}$ is semisimple, and we define $\mathfrak{k}_r = \mathfrak{k}_{r,0}^{ss} \oplus c(\mathfrak{g}_{r,0})$ if $\mathfrak{g}_{r,0}$ has center $c(\mathfrak{g}_{r,0})$. We assume $\mathfrak{k}_r$ to be of compact type and reductive. As usual we drop the index $r$ to mean complexification.

Hence, we decompose $\mathfrak{g}$ as:

\begin{equation}
\mathfrak{g} = \mathfrak{k}_0 \oplus \mathfrak{p}, \quad \mathfrak{p} := \mathfrak{p}_0 \oplus \mathfrak{g}_1.
\end{equation}

**Definition 2.4.** We call the pair $(\mathfrak{g}_r, \mathfrak{k}_r)$, described above, a $(\mathfrak{g}_r, \mathfrak{k}_r)$ pair of Lie superalgebras. Note that $\mathfrak{k}_r = \mathfrak{k}_{r,0}$.

We give the same definition for the complex pair of Lie superalgebras $(\mathfrak{g}, \mathfrak{k})$.

Let us now further assume that

\[ \text{rk}(\mathfrak{g}_{r,0}) = \text{rk}(\mathfrak{k}_r) \]

Then we can choose a CSA $\mathfrak{h}_r = \mathfrak{h}_{r,0}$ of $\mathfrak{g}_{r,0}$ so that

\begin{equation}
\mathfrak{h}_r \subset \mathfrak{k}_r \subset \mathfrak{g}_r, \quad \mathfrak{h} \subset \mathfrak{k} \subset \mathfrak{g}
\end{equation}

$h$ is then a CSA of $\mathfrak{k}, \mathfrak{g}_0$ and $\mathfrak{g}$.

We fix a positive system $P = P_0 \cup P_1$ of roots for $(\mathfrak{g}, \mathfrak{h})$ and write $\alpha > 0$ interchangeably with $\alpha \in P$; $P_0$ denotes the even roots, while $P_1$ the odd roots in $P$.

We say that a root $\alpha$ is *compact* (resp. *non-compact*) if $\mathfrak{g}_\alpha \subseteq \mathfrak{k}$ (resp. $\mathfrak{g}_\alpha \subseteq \mathfrak{p}$). By [2], we have

\[ \Delta = \Delta_k \cup \Delta_n \]

where $\Delta_k$ (resp.$\Delta_n$) denotes the set of compact (resp. non-compact) roots.

We call $P_k$ the set of positive compact roots and $P_n$ the set of positive non-compact roots, $P = P_k \coprod P_n$. We define:

\[ \mathfrak{p}^+ = \sum_{\alpha \in P_n} \mathfrak{g}_\alpha \subseteq \mathfrak{p}, \quad \mathfrak{p}^- = \sum_{\alpha \in -P_n} \mathfrak{g}_\alpha \subseteq \mathfrak{p} \]

that is $\mathfrak{p}^+$ (resp. $\mathfrak{p}^-$) is the direct sum of the positive (resp. negative) non-compact root spaces.

**Definition 2.5.** We say that the positive system $P = P_0 \cup P_1$ is *admissible* if:

1. $\mathfrak{p}^+$ is $\mathfrak{k}$-stable, that is, $[\mathfrak{k}, \mathfrak{p}^+] \subseteq \mathfrak{p}^+$;
(2) $\mathfrak{p}^+$ is a Lie subsuperalgebra, that is $[\mathfrak{p}^+, \mathfrak{p}^+] \subset \mathfrak{p}^+$.

The two conditions are equivalent to saying that $\mathfrak{e} \oplus \mathfrak{p}^+$ is a subsuperalgebra of $\mathfrak{g}$ and $\mathfrak{p}^+$ an ideal in $\mathfrak{e} + \mathfrak{p}^+$. Notice that these conditions imply that $P_0$ is an admissible system for $\mathfrak{g}^{ss}_0$ the semisimple part of $\mathfrak{g}_0$ and consequently that $\mathfrak{p}^+_0$ is abelian. If $P$ is a positive system and $P_0$ is admissible, to verify $P$ is admissible, we only need to check that:

$$[\mathfrak{p}_1^+, \mathfrak{p}_1^+] \subset \mathfrak{p}_0^+, \quad [\mathfrak{e}, \mathfrak{p}_1^+] \subset \mathfrak{p}_1^+$$

We now want to prove the existence of admissible systems.

**Theorem 2.6.** Let $P_0$ be an admissible system for $\mathfrak{g}^{ss}_0$, the semisimple part of $\mathfrak{g}_0$. Then $\mathfrak{g}$ has an admissible system $P$ containing $P_0$.

**Proof.** It is a known fact that if $\mathfrak{g}$ is a simple Lie algebra and $P = P_k \cup P_n$ is an admissible system, the only other admissible system containing $P_k$ is $P_k \cup (-P_n)$. Due to the irreducibility of the $\mathfrak{e}$-modules $\mathfrak{p}^\pm_0$ and the fact each weight is multiplicity free, any other admissible system has the form:

$$P'_k \cup (\pm P_n)$$

for some compact positive system $P'_k$. In other words, the noncompact part of an admissible system is fixed modulo a sign.

Hence, if $\mathfrak{g}$ is a semisimple Lie algebra the admissible systems containing a given $P_k$ are conjugate under the action of $\mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$, where we have one copy of $\mathbb{Z}_2$ for each of the simple components of $\mathfrak{g}$. Hence, different admissible system are of the form:

$$\bigcup_i (P'_{k,i} \cup \epsilon_i P_{n,i})$$

where $P'_{k,i} \cup P_{n,i}$ is a fixed admissible system for the $i$-th factor and $\epsilon_i = \pm 1$.

We can apply these considerations to the semisimple part $\mathfrak{g}^{ss}_0$ of the Lie superalgebra $\mathfrak{g}$, and notice that, if we show that there exists a super admissible system containing a particular admissible system $P_0$, then we are done. Indeed if we have

$$P = P_0 \cup P_1 = \bigcup_i (P_0)_{k,i} \cup (P_0)_{n,i} \cup (P_1)_{n,i}$$

then any other admissible system for $\mathfrak{g}^{ss}_0$ is of the form

$$\bigcup_i (P'_{0,k,i} \cup \epsilon_i (P_0)_{n,i})$$

and hence an easy check shows that

$$\bigcup_i (P'_{0,k,i} \cup \epsilon_i (P_0)_{n,i} \cup \epsilon_i (P_1)_{n,i})$$

is an admissible system for $\mathfrak{g}$.

The fact that, for a particular admissible system $P_0$ for $\mathfrak{g}^{ss}_0$, there exists an admissible system of $\mathfrak{g}$ containing $P_0$, will be proven in the remaining part of this section by a case by case analysis.

The Lie superalgebras of classical type and their real forms have been classified in [30] (see also [43, 42]), so we proceed to a case by case analysis. We briefly recall the ordinary setting.
The only simple basic classical real Lie algebras $g_{r,0}$ giving rise to an hermitian symmetric space, condition equivalent to have an admissible system, are:

- AIII. $g_{r,0} = su(p, q)$, $g_0 = sl_{p+q} (\mathbb{C})$, $\frak{e}_{r,0} = su(p) \oplus su(q) \oplus i\mathbb{R}$, $\frak{e} = sl_p (\mathbb{C}) \oplus sl_q (\mathbb{C}) \oplus \mathbb{C}$.
- BDI $(q = 2)$. $g_{r,0} = so_0 (p, 2)$, $g_0 = so_0 (p + 2)$, $\frak{e}_{r,0} = so_0 (p) \oplus so_0 (2)$, $\frak{e} = so_0 (p) \oplus so_0 (2)$.
- DIII. $g_{r,0} = so^* (2n)$, $g_0 = so_{C} (2n)$, $\frak{e}_{r,0} = \frak{u} (n)$, $\frak{e} = gl_n (\mathbb{C})$.
- CI. $g_{r,0} = sp_{n} (\mathbb{R})$, $g_0 = sp_{n} (\mathbb{C})$, $\frak{e}_{r,0} = \frak{u} (n)$, $\frak{e} = gl_n (\mathbb{C})$.

We remark that there are two other Lie algebras corresponding to hermitian symmetric spaces, namely EIII and EVII, however neither of them will appear in the even part of a basic classical Lie superalgebra $g$, $g_1 \neq 0$.

Let us now proceed and examine the various cases in the super setting.

**Type A. Case:** $A(m-1, n-1) = sl_{m|n} (\mathbb{C})$, $m \neq n$. The even part is

$$g_0 = sl_m (\mathbb{C}) \oplus sl_n (\mathbb{C}) \oplus \mathbb{C}$$

We have 4 possible real forms of $A(m-1, n-1)_0$ that correspond to hermitian symmetric spaces. They are given by the following table (relative to the semisimple part of $\frak{g}$):

| type     | $sl_m (\mathbb{C}), m = p + q$ | $sl_n (\mathbb{C}), n = r + s$ |
|----------|---------------------------------|---------------------------------|
| non-compact | $su(p, q)$                      | $su(r, s)$                      |
| compact  | $su(p + q)$                     | $su(r + s)$                     |

Note that $p$, $q$, $r$, $s$ can take also the value 0.

The only real Lie algebra which is the even part of a real form of $g$ is:

$$g_{r,0} = su(p, q) \oplus su(r, s) \oplus \frak{u} (1)$$

(see [42]). We now describe the root system of $g = sl_{m|n} (\mathbb{C})$. Take as CSA $\frak{h}$ the diagonal matrices:

$$\frak{h} = \{ \frak{h} = \text{diag}(a_1, \ldots, a_m, b_1, \ldots, b_n) \}$$

and define $\epsilon_i (d) = a_i$, $\delta_j (d) = b_j$, for $i = 1, \ldots, m$ and $j = 1, \ldots, n$. Choose the simple system:

$$\Pi = \{ \epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_0 - \delta_1, \delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n \}$$

We have 3 non-compact simple roots, 2 even and 1 odd:

$$\epsilon_p - \epsilon_{p+1}, \quad \delta_r - \delta_{r+1}, \quad \epsilon_m - \delta_1$$

According to the simple system, we have:

$$P_k = \{ \epsilon_i - \epsilon_j \mid 1 \leq i < j \leq p \} \cup \{ \epsilon_i - \epsilon_j \mid p + 1 \leq i < j \leq m \}$$

$$\cup \{ \delta_i - \delta_j \mid 1 \leq i < j \leq r \} \cup \{ \delta_i - \delta_j \mid r + 1 \leq i < j \leq n \}$$

$$P_{n,0} = \{ \epsilon_i - \epsilon_j \mid 1 \leq i \leq p < j \leq m \} \cup \{ \delta_i - \delta_j \mid 1 \leq i \leq r < j \leq n \}$$

$$P_{n,1} = \{ \epsilon_i - \delta_j \mid 1 \leq i \leq m, 1 \leq j \leq n \}$$

The following checks are immediate:

1. $[\frak{e}_0, \frak{p}_0^+] \subset \frak{p}_0^+$, $[\frak{e}_0, \frak{p}_1^+] \subset \frak{p}_1^+$.
2. $[\frak{p}_0^+, \frak{p}_0^-] = 0$, $[\frak{p}_0^+, \frak{p}_1^-] \subset \frak{p}_1^+$, $[\frak{p}_1^+, \frak{p}_1^-] = 0$. 
Hence we have produced an admissible system.

**Type B. Case:** $B(m,n) = \text{osp}_\mathbb{C}(2m + 1|2n)$, $m \neq 0$. The even part is

$$B(m,n)_0 = \text{osp}_\mathbb{C}(2m + 1|2n) = \text{so}_\mathbb{C}(2m + 1) \oplus \text{sp}_n(\mathbb{C})$$

Reasoning as in the previous cases, that is reasoning on the ordinary setting and knowing the classification of the real forms there, we have only four possibilities for the choice of the real form of $B(m|n)_0$:

| Type   | $\text{so}_\mathbb{C}(2m + 1)$ | $\text{sp}_n(\mathbb{C})$ |
|--------|--------------------------------|--------------------------|
| non-compact | $\text{so}_\mathbb{R}(2, 2m - 1)$ | $\text{sp}_n(\mathbb{R})$ |
| compact | $\text{so}_\mathbb{R}(2m + 1)$ | $\text{sp}(n)$ |

The only case for which the real form $\mathfrak{g}_{r,0}$ extends to a real form of the Lie superalgebra $\mathfrak{g}$ is

$$\mathfrak{g}_{r,0} = \text{so}_\mathbb{R}(2, 2m - 1) \oplus \text{sp}_n(\mathbb{R})$$

(see [42]). The corresponding maximal compact subalgebra is

$$\mathfrak{k}_0 = \text{so}_\mathbb{R}(2) \oplus \text{so}_\mathbb{R}(2m - 1) \oplus \text{u}(n)$$

Using the same notations as in [33], we choose the simple system:

$$\Pi = \{\epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_m, \delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n, \delta_n - \epsilon_1\}$$

We have one simple non-compact even root $\epsilon_1 - \epsilon_2$ and one non-compact simple odd root: $\delta_n - \epsilon_1$. So we have:

$$P_{n,0} = \{\epsilon_i \pm \epsilon_j \mid 1 < j \leq m\} \cup \{\epsilon_1\} \cup \{\delta_i + \delta_j \mid 1 \leq i, j \leq n\}$$

$$P_{n,1} = \{\epsilon_i \pm \epsilon_j \mid 1 \leq i \leq n, 1 \leq j \leq m\} \cup \{\delta_i \mid 1 \leq i \leq n\}$$

$$P_k = \{\epsilon_i \pm \epsilon_j \mid 1 < i < j \leq m\} \cup \{\epsilon_i \mid 1 < i \leq m\} \cup \{\delta_i - \delta_j \mid 1 \leq i < j \leq n\}$$

In order to check the $\text{ad}(\mathfrak{k}_0)$ invariance of $\mathfrak{p}_0^+$ and $\mathfrak{p}_1^+$, we need to verify that summing one of the roots in $P_k \cup -P_k$ to one in $P_{n,0}$ or $P_{n,1}$ we remain in $P_{n,0}$ or $P_{n,1}$. The check is straightforward. Similarly one verifies that $\mathfrak{p}^+ = \mathfrak{p}_0^+ + \mathfrak{p}_1^+$ is a Lie subsuperalgebra, hence we have produced an admissible system.

**Type B. Case:** $B(0,n) = \text{osp}_\mathbb{C}(1|2n)$. In this case, the even part is

$$B(0,n)_0 = \text{osp}_\mathbb{C}(1|2n)_0 \cong \text{sp}_n(\mathbb{C})$$

The only real form of interest to us is:

$$\mathfrak{g}_{r,0} = \text{sp}_n(\mathbb{R})$$

corresponding to the maximal compact subalgebra $\mathfrak{k}_0 = \text{u}(n)$.

Choose the simple system:

$$\Pi = \{\delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n, \delta_n\}$$
We have one simple non-compact odd root $\delta_n$. So we have:

\[ P_{n,0} = \{ \delta_i + \delta_j \mid 1 \leq i, j \leq n \} \]
\[ P_{n,1} = \{ \delta_i \mid 1 \leq i \leq n \} \]
\[ P_k = \{ \delta_i - \delta_j \mid 1 \leq i < j \leq n \} \]

Both the checks for properties (1) and (2) in Def. 2.5 are immediate.

**Type D. Case:** $D(m,n) = \text{osp}_{\mathbb{C}}(2m|2n)$. The even part is given by:

\[ D(m,n)_0 = \text{osp}_{\mathbb{C}}(2m|2n)_0 = \text{so}_{\mathbb{C}}(2m) \oplus \text{sp}_n(\mathbb{C}) \]

The possibilities for the choice of the real form of $D(m,n)_0$ are:

| Type   | $\text{so}_{\mathbb{C}}(2m+1)$ | $\text{sp}_n(\mathbb{C})$ |
|--------|-------------------------------|---------------------------|
| Non-compact   | $\text{so}_{\mathbb{R}}(2,2m-2)$ | $\text{sp}_n(\mathbb{R})$ |
| Compact       | $\text{so}_{\mathbb{R}}(2m)$    | $\text{sp}(n)$            |
| Non-compact   | $\text{so}^*(2m)$              | $\text{sp}_n(\mathbb{R})$ |
| Compact       | $\text{so}_{\mathbb{R}}(2m)$    | $\text{sp}_n(\mathbb{R})$ |

Again by [42] we have that the only possibilities for $\mathfrak{g}_{r,0}$ are:

\[ \mathfrak{g}_{r,0} = \text{so}_{\mathbb{R}}(2,2m-2) \oplus \text{sp}_n(\mathbb{R}) \]

or

\[ \mathfrak{g}_{r,0} = \text{so}^*(2m) \oplus \text{sp}_n(\mathbb{R}) \]

The corresponding maximal compact subalgebra in the first case is

\[ \mathfrak{k}_{r,0} = \text{so}_{\mathbb{R}}(2) \oplus \text{so}_{\mathbb{R}}(2m-2) \oplus \mathfrak{u}(n) \]

Choose the simple system:

\[ \Pi = \{ \epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_{m-1} + \epsilon_m, \delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n, \delta_n - \epsilon_1 \} \]

We have one simple non-compact even root $\epsilon_1 - \epsilon_2$ and one non-compact simple odd root: $\delta_n - \epsilon_1$.

\[ P_{n,0} = \{ \epsilon_1 \pm \epsilon_j \mid 1 < j \leq m \} \cup \{ \delta_i + \delta_j \mid 1 \leq i, j \leq n \} \]
\[ P_{n,1} = \{ \epsilon_i \pm \epsilon_j \mid 1 \leq j \leq m \mid 1 \leq i \leq n \} \]
\[ P_k = \{ \epsilon_i \pm \epsilon_j \mid 1 < i < j \leq m \} \cup \{ \delta_i - \delta_j \mid 1 \leq i < j \leq n \} \]

The calculation of ad($\mathfrak{k}_0$)-stability is exactly as before and similarly for the verification of the property (2) in Def. 2.5.

We now go to the second case.

The maximal compact subalgebra is

\[ \mathfrak{k}_{r,0} = \mathfrak{u}(m) \oplus \mathfrak{u}(n) \]

Choose the same simple system as before:

\[ \Pi = \{ \epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_{m-1} + \epsilon_m, \delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n, \delta_n - \epsilon_1 \} \]
Now the simple non-compact even root $\epsilon_{m-1} + \epsilon_m$ while the non-compact simple odd root is as before $\delta_n - \epsilon_1$.

$$P_{n,0} = \{\epsilon_i + \epsilon_j \mid 1 \leq i < j \leq m\} \cup \{\delta_i + \delta_j \mid 1 \leq i, j \leq n\}$$

$$P_{n,1} = \{\delta_i \pm \epsilon_j \mid 1 \leq i \leq n, 1 \leq j \leq m\}$$

$$P_k = \{\epsilon_i - \epsilon_j \mid 1 < i < j \leq m\} \cup \{\delta_i - \delta_j \mid 1 \leq i < j \leq n\}$$

The calculation of $\text{ad}(t_0)$-stability is exactly as before and similarly for the verification of the property (2) in Def. 2.5.

**Type C. Case:** $C(n) = \text{osp}_C(2|2n - 2)$. We have only one possible real form extending to a real form of the whole $g$ namely:

$$g_{r,0} = so_R(2) \oplus sp_{n-1}(R)$$

Choose the simple system:

$$\Pi = \{\epsilon - \delta_1, \delta_1 - \delta_2, \ldots, \delta_{n-2} - \delta_{n-1}, 2\delta_{n-1}\}$$

We have one simple non-compact odd root $\epsilon_1 - \delta_1$ and one non-compact simple even root: $2\delta_{n-1}$.

$$P_{n,0} = \{\delta_i + \delta_j \mid 1 \leq i, j \leq n - 1\}$$

$$P_{n,1} = \{\epsilon \pm \delta_j \mid 1 \leq j \leq n - 1\}$$

$$P_k = \{\delta_i - \delta_j \mid 1 < i < j \leq n - 1\}$$

The verification of the two properties (1) and (2) listed above is the same as in the $B$ case.

We now examine the exceptional Lie superalgebras of classical type.

**Case:** $D(2, 1; \alpha)$. We have two possible real forms of $D(2, 1; \alpha)_0 = sl_2(C) \oplus sl_2(C) \oplus sl_2(C)$ admitting an extension to the whole $D(2, 1; \alpha)$ (see [12]) namely:

$$g_{r,0} = sl_2(R) \oplus sl_2(R) \oplus sl_2(R), \quad \text{and} \quad g_{r,0} = sl_2(R) \oplus su(2) \oplus su(2).$$

We first examine the case $g_{r,0} = sl_2(R) \oplus sl_2(R) \oplus sl_2(R)$. The root system is:

$$\Delta_0 = \{\pm 2\epsilon_i \mid i = 1, 2, 3\}, \quad \Delta_1 = \{\pm \epsilon_1 \pm \epsilon_2 \pm \epsilon_3\}$$

All roots are non-compact and the positive roots corresponding to the simple system:

$$\Pi = \{\epsilon_1 + \epsilon_2 + \epsilon_3, -2\epsilon_2, -2\epsilon_3\}$$

form an admissible system. In fact the only thing to check is that $[p^+_1, p^+_1] \subset p^+_0$, where $P_{n,1} = \{\epsilon_1 \pm \epsilon_2 \pm \epsilon_3\}$ and $P_{n,0}$ consists of the positive even roots. This is immediate.

Consider now the case $g_{r,0} = sl_2(R) \oplus su(2) \oplus su(2)$ and fix the positive system:

$$\Pi = \{\epsilon_1 + \epsilon_2 + \epsilon_3, -2\epsilon_2, -2\epsilon_3\}$$

where $\epsilon_1 + \epsilon_2 + \epsilon_3$ is non-compact, while $-2\epsilon_2, -2\epsilon_3$ are compact. We have that $p^+$ is spanned by the root spaces corresponding to the roots:

$$2\epsilon_1, \quad \epsilon_1 + \epsilon_2 + \epsilon_3, \quad \epsilon_1 - \epsilon_2 - \epsilon_3, \quad \epsilon_1 - \epsilon_2 + \epsilon_3, \quad \epsilon_1 + \epsilon_2 - \epsilon_3.$$
Case: $F(4)$. The root system is:
\[
\Delta_0 = \{ \pm \epsilon_i \pm \epsilon_j, \pm \epsilon_i, \pm \delta, \quad i = 1, 2, 3 \}, \quad \Delta_1 = \{ 1/2(\pm \epsilon_1 \pm \epsilon_2 \pm \epsilon_3 \pm \delta) \}
\]
$\epsilon_1$, $\epsilon_2$, $\epsilon_3$ are the roots corresponding to $\mathfrak{so}_7(\mathbb{C})$, while $\delta$ corresponds to $\mathfrak{sl}_2(\mathbb{C})$. Choose the simple system (refer to [30] pg 53):
\[
\Pi = \{ 1/2(\epsilon_1 + \epsilon_2 + \epsilon_3 + \delta), -\epsilon_1, -\epsilon_1 - \epsilon_2, -\epsilon_2 - \epsilon_3 \}
\]
We have two real forms of the even part $F(4)_0 = \mathfrak{sl}_2(\mathbb{C}) \oplus \mathfrak{so}_7(\mathbb{C})$ which extend to the whole $F(4)$:
\[
\mathfrak{g}_{r,0} = \mathfrak{sl}_2(\mathbb{R}) \oplus \mathfrak{so}_7(\mathbb{R}), \quad \mathfrak{g}_{r,0} = \mathfrak{su}(2) \oplus \mathfrak{so}_7(\mathbb{R})
\]
Let us first examine
\[
\mathfrak{g}_{r,0} = \mathfrak{sl}_2(\mathbb{R}) \oplus \mathfrak{so}_7(\mathbb{R}), \quad \mathfrak{t}_r = \mathfrak{so}_2(2) \oplus \mathfrak{so}_7(\mathbb{R})
\]
We have that $1/2(\epsilon_1 + \epsilon_2 + \epsilon_3 + \delta)$ is the only non-compact simple root. With such a choice:
\[
\begin{align*}
P_k &= \{ \pm \epsilon_i - \epsilon_j, 1 \leq i < j \leq 3 \} \cup \{ -\epsilon_i, 1 \leq i \leq 3 \} \\
P_{n,0} &= \{ \delta \}, \\
P_{n,1} &= \{ 1/2(\pm \epsilon_1 \pm \epsilon_2 \pm \epsilon_3 + \delta) \}
\end{align*}
\]
One can easily check that such $\mathfrak{p}^+$ is $\text{ad}(\mathfrak{t})$-invariant and $[\mathfrak{p}^+_1, \mathfrak{p}^+_1] \subset \mathfrak{p}^+_0$.

We now consider the case:
\[
\mathfrak{g}_{r,0} = \mathfrak{su}(2) \oplus \mathfrak{so}_7(\mathbb{R}, 2, 5), \quad \mathfrak{t}_r = \mathfrak{so}_2(2) \oplus \mathfrak{so}_7(\mathbb{R}, 2, 5)
\]
The simple root system described above is not suitable, since the corresponding even positive system is not admissible for the given real form (notice that both the roots $\epsilon_1 - \epsilon_2$ and $-\epsilon_3$ are positive and compare with case $B(m, n)$ discussed above). In order to obtain the correct simple system we need to transform it using the (unique) element $w$ of the Weyl group such that $w(\Pi_0) = \Pi'_0$, where $\Pi'_0$ leads to an admissible system for the real form $\mathfrak{sl}_2(\mathbb{R}) \oplus \mathfrak{so}_7(\mathbb{R}, 2, 5)$ of $F(4)$:
\[
\Pi_0 = \{ -\epsilon_1, \epsilon_1 - \epsilon_2, \epsilon_2 - \epsilon_3 \} \quad \text{maps to} \quad \Pi'_0 = \{ \epsilon_3, \epsilon_1 - \epsilon_2, \epsilon_2 - \epsilon_3 \}
\]
Now, taking the image of the simple system $\Pi$ under $w$ we obtain:
\[
\Pi' := w(\Pi) = \{ \epsilon_3, \epsilon_1 - \epsilon_2, \epsilon_2 - \epsilon_3, (1/2)(w(\epsilon_1 + \epsilon_2 + \epsilon_3 + \delta)) \}
\]
The odd positive roots are then characterized by having $+\delta$ and not $-\delta$ in their expression. We take as the simple non-compact roots:
\[
1/2(w(\epsilon_1 + \epsilon_2 + \epsilon_3 + \delta)), \quad \epsilon_1 - \epsilon_2.
\]
With such a choice we obtain:
\[
\begin{align*}
P_{n,0} &= \{ \delta, \epsilon_1, \epsilon_1 \pm \epsilon_j, 1 \leq i < j \leq 3 \} \\
P_{n,1} &= \{ 1/2(\pm \epsilon_1 \pm \epsilon_2 \pm \epsilon_3 + \delta) \} \\
P_k &= \{ \epsilon_i \pm \epsilon_j, 1 < i < j \leq 3 \} \cup \{ \epsilon_i, i = 2, 3 \}
\end{align*}
\]
$\mathfrak{p}^+_0$ is $\text{ad}(\mathfrak{t})$-invariant (this is an immediate check, but it also comes from the ordinary theory), while $\mathfrak{p}^+_1$ is $\text{ad}(\mathfrak{t})$-invariant since no roots in $P_k$ contain $\delta$. Finally $[\mathfrak{p}^+_1, \mathfrak{p}^+_1] \subset \mathfrak{p}^+_0$.

Case: $G(3)$. The only real form of $G(3)_0$ with an admissible system is:
\[
\mathfrak{sl}_2(\mathbb{R}) \oplus \mathfrak{g}_2
\]
where $G_2$ is the compact form of $G_2$. Choose the simple system (refer to [30] pg 53):

$$\Pi = \{\delta + \epsilon_1, \epsilon_2, \epsilon_3 - \epsilon_2\}$$

where the linear functions $\epsilon_i$ correspond to $G_2$, $\epsilon_1 + \epsilon_2 + \epsilon_3 = 0$ and $\delta$ to $A_1$. The only simple non-compact root is $\delta + \epsilon_1$. We have:

$$P_k = \{-\epsilon_1, \epsilon_i, 1 < i \leq 3\} \cup \{\epsilon_3 - \epsilon_2, \epsilon_2 - \epsilon_1, \epsilon_3 - \epsilon_1\}$$

$$P_{n,0} = \{2\delta\}$$

$$P_{n,1} = \{\delta, \delta \pm \epsilon_i, 1 \leq i \leq 3\}$$

The properties (1) and (2) of Def. 2.5 are verified by an easy calculation.

No other Lie superalgebra of classical type satisfying our hypothesis admits a real form whose even part corresponds to an hermitian symmetric space, hence our case by case analysis ends here.

2.3. **Harish-Chandra modules.** Consider a $(g, \mathfrak{k})$ pair of Lie superalgebras as above, with $\text{rk } g = \text{rk } \mathfrak{k}$ and $\mathfrak{k} = \mathfrak{k}_0$. We can choose a CSA $\mathfrak{h} = \mathfrak{h}_0$ so that $\mathfrak{h} \subset \mathfrak{k} \subset g$ and $\mathfrak{h}$ will be a CSA of both $\mathfrak{k}$ and $g$. We fix a positive system $P = P_0 \cup P_1$ of roots for $(g, \mathfrak{h})$.

**Definition 2.7.** Let the complex super vector space $V$ be a $g$-module. We say that $V$ is a $(g, \mathfrak{k})$-module if

$$V = \sum_{\theta \in \Theta} V(\theta)$$

where the sum is algebraic and direct, $\Theta$ denotes the set of equivalence classes of the finite dimensional irreducible representations of $\mathfrak{k}$ and $V(\theta)$ is the sum of all representations occurring in $V$ and belonging to the class $\theta \in \Theta$. We say that the $(g, \mathfrak{k})$-module $V$ is an **Harish-Chandra module** (or **HC-module** for short) if each $V(\theta)$ is finite dimensional and $V$ is finitely generated as $U(g)$ module.

We are interested in highest weight modules (with respect to $P$) which are also HC-modules (see Ref. [40] for an exhaustive introduction to highest weight modules).

**Proposition 2.8.** Let $U$ be a highest weight $g$-module with highest weight $\lambda$ and highest weight vector $v$. The following are equivalent:

1. $\dim(U(\mathfrak{k})v) < \infty$;
2. $U$ is a $(g, \mathfrak{k})$-module;
3. $U$ is an HC-module.

If these conditions are true, then $U(\mathfrak{k})v$ is an irreducible $\mathfrak{k}$-module.

**Proof.** The proof is very similar to the classical case; we shall nevertheless rewrite it for clarity of exposition. By the ordinary theory we know that the action of $\mathfrak{k}$ (which is an ordinary reductive Lie algebra) is decomposable if and only if the center $c$ of $\mathfrak{k}$ acts semisimply. Given $c \subset \mathfrak{h}$, if $U$ is a highest weight module (on which $\mathfrak{h}$ acts diagonally) we have that $c$ acts semisimply on $U$. We now show (1) $\implies$ (2). Let $U^\mathfrak{k}$ denote the $\mathfrak{k}$-finite vectors in $U$ (i.e., those vectors lying in a finite dimensional $\mathfrak{k}$-stable subspace). It is easy to check $U^\mathfrak{k}$ is a submodule and since the highest weight vector $v \in U^\mathfrak{k}$, we have $U = U^\mathfrak{k}$ and this proves (2). We now show (2) $\implies$ (3). According to the previous definition, we need to show that $U(\theta)$
is finite dimensional. By contradiction, assume this is not the case and let \( \mu \) a weight of \( U(\theta) \). Such a weight occurs with infinite multiplicity, and we have \( \dim(U(\theta)_\mu) = \infty \). This is in contradiction with the well known fact that in a highest weight module the weights occur with finite multiplicities. (3) \( \implies \) (1) is straightforward. We now go about the proof of the irreducibility of \( U(\mathfrak{t})v \). As we remarked at the beginning \( \mathfrak{c} \) acts as scalar: \( cw = \lambda(c)w \), for \( c \in \mathfrak{c} \) and \( w \in U(\mathfrak{t})v \). So we have \( U(\mathfrak{t})v = U(\mathfrak{t}')v \) with \( \mathfrak{t}' = [\mathfrak{t}, \mathfrak{t}] \). \( U(\mathfrak{t}')v \) is a finite dimensional highest weight module for the semisimple Lie algebra \( \mathfrak{t}' \) and consequently it is irreducible.

We now want to define the universal super HC-module of highest weight \( \lambda \). Choose \( P = P_k \cup P_n \), a positive admissible system.

Let \( \lambda \in \mathfrak{h}^* \) be such that \( \lambda(H_\alpha) \) is an integer \( \geq 0 \) for all \( \alpha \in P_k \). Let \( F = F_\lambda \) be the irreducible finite dimensional module for \( \mathfrak{k} \) of highest weight \( \lambda \). Note that \( \lambda(H_\beta) \) can be arbitrary for positive non-compact roots \( \beta \). Write
\[
\mathfrak{q} = \mathfrak{k} \oplus \mathfrak{p}^+.
\]
Recall that \( [\mathfrak{k}, \mathfrak{p}^+] \subset \mathfrak{p}^+ \) and so we can turn \( F \) into a left \( \mathfrak{q} \)-module by letting \( \mathfrak{p}^+ \) act trivially.

Define
\[
(2.3) \quad U^\lambda = U(\mathfrak{g}) \otimes_{U(\mathfrak{q})} F
\]
and view \( U^\lambda \) as a \( U(\mathfrak{g}) \)-module by left action \( a(b \otimes f) = ab \otimes f \).

Let
\[
(2.4) \quad \rho = \frac{1}{2} \sum_{\alpha \in P_0} \alpha - \frac{1}{2} \sum_{\alpha \in P_1} \alpha.
\]

**Theorem 2.9.** Let the notation be as above.

1. \( U^\lambda \) is the universal HC-module of highest weight \( \lambda \).
2. \( U^\lambda \) has a unique irreducible quotient, which is the unique (up to isomorphism) irreducible highest weight Harish-Chandra module with highest weight \( \lambda \).

**Proof.** (1). Let \( f^\lambda \) be the highest weight vector for \( F \). Then \( 1 \otimes f^\lambda \) is such that:
\[
X_\alpha(1 \otimes f^\lambda) = 0, \quad \alpha > 0, \quad U(\mathfrak{g})(1 \otimes f^\lambda) = U^\lambda
\]
hence \( 1 \otimes f^\lambda \) is the highest weight vector of \( U^\lambda \). To prove universality, let \( V \) be a highest weight HC-module with highest weight vector \( v \). The map
\[
F \rightarrow V, \quad uf^\lambda \mapsto uv, \quad (a \in U(\mathfrak{g}), \ v \in F)
\]
extends to a linear map \( L : U(\mathfrak{g}) \otimes_F F \rightarrow V \) which is onto. Since \( L(au \otimes f) - L(a \otimes uf) = 0 \) for all \( a \in U(\mathfrak{g}), \ u \in U(\mathfrak{q}), \ f \in F \), it follows that \( L \) descends to a map \( U^\lambda \rightarrow V \) which is obviously a \( U(\mathfrak{g}) \)-module map.

(2) It follows from the standard theory of highest weight modules that \( U^\lambda \) has a unique irreducible quotient, which is a highest weight HC-module of highest weight \( \lambda \). It is the unique irreducible highest weight HC-module of highest weight \( \lambda \) by universality (point 1).

\[\square\]
We shall now study the structure of $U^\lambda$ as a $q$-module for arbitrary $\lambda$ with $\lambda(H_\alpha)$ an integer $\geq 0$ for all $\alpha \in P_k$. For this we need a standard lemma.

**Lemma 2.10.** Let $g$ be a field and $A,B$ algebras over $g$. Suppose $B \subset A$, $A$ is a free right $B$-module, $F$ a left $B$-module, and $V = A \otimes_B F$. If $(a_i)$ is a free basis for $A$ as a right $B$-module, and $L = \sum_i g.a_i$, then the map taking $\ell \otimes_g f$ to $\ell \otimes_B f$ is a linear isomorphism of $L \otimes_g F$ with $V$.

We regard $U(p^-) \otimes F$ as a $U(p^-)$-module by $a,b \otimes f \mapsto ab \otimes f$. Since $p^-$ is stable under $\text{ad} \, t$ we may view $U(p^-) \otimes F$ as a $t$-module also.

**Corollary 2.11.** The map $\varphi : a \otimes f \mapsto a \otimes_{U(q)} f$ is a linear isomorphism of $U(p^-) \otimes F$ with $U^\lambda$ that intertwines both the actions of $U(p^-)$ and $U(t)$. In particular, $U^\lambda$ is a free $U(p^-)$-module with basis $1 \otimes_{U(q)} f_j$ where $(f_j)$ is a basis for $F$.

**Proof.** Since $g = p^- \oplus q$ it follows that $a \otimes b \mapsto ab$ is a linear isomorphism of $U(p^-) \otimes U(q)$ with $U(g)$. It is clear from this that $U(g)$ is a free right $U(q)$-module, and that any basis of $U(p^-)$ is a free right $U(q)$-basis for $U(g)$. Lemma 2.10 now applies and shows that $\varphi$ is an isomorphism. It obviously commutes with the action of $U(p^-)$. The verification of the commutativity with respect to $t$ is also straightforward. 

### 2.4 Irreducibility of the universal HC-module.

In this section we want to prove the following theorem which gives a sufficient condition for the irreducibility of the universal HC-module. For similar modules in the classical setting, see Theorem 3 in [27], IV (1955), pg 770.

Let our hypotheses and notation be as in Sec. 2.3.

**Theorem 2.12.** Let $g$ be one of the complex basic Lie superalgebras in the list [7], and let $U^\lambda$ be the universal Harish-Chandra module, with highest weight $\lambda$ associated with the (finite dimensional) representation $F$ of $t$, as defined by (2.3). Let $\rho$ be as in eq. (2.4). If

$$\lambda + \rho)(H_\gamma) \leq 0 \quad \text{for all } \gamma \in P_n \quad \text{and} \quad < 0 \quad \text{for } \gamma \text{ isotropic},$$

then $U^\lambda$ is irreducible.

The proof of this theorem relies on a result stated by V. Kac in [32] and proved by M. Gorelik in [24], that we give here, as Theorem 2.13 without proof (see also [10] Sec. 13.2). Here $W$ denotes the Weyl group of $g$ and $S(h)^W$ denotes the set of $W$-invariant symmetric tensors on $h$. In the following we will use the identification of $S(h)$ with the superalgebra of polynomials $\text{Pol}(h^*)$ without mention.

**Theorem 2.13.** The Harish-Chandra isomorphism

$$\beta : Z(g) \longrightarrow S(h)^W$$

for basic Lie superalgebras identifies the center $Z(g)$ of the universal enveloping algebra with the subalgebra $I(h)$ of $S(h)^W$:

$$I(h) = \{ \phi \in S(h)^W \mid \phi(\lambda + t\alpha) = \phi(\lambda), \forall \lambda \in \langle \alpha \rangle^\perp, \alpha \text{ isotropic, } \forall t \in \mathbb{C} \}$$

(a root $\alpha$ is isotropic if $(\alpha, \alpha) = 0$).
This theorem allows us to show that when a weight $\lambda$ is typical that is
\[
\langle \lambda + \rho, \alpha \rangle \neq 0 \quad \forall \alpha \text{ isotropic}
\]
all of the maximal weights (with respect to a highest weight vector in a submodule) in the highest weight representation of highest weight $\lambda$ are conjugate under the affine action of the Weyl group, that we denote as $s.\lambda$. Notice that the condition (2.5) implies that the weight $\lambda$ in Theorem 2.12 is typical.

We now recall few results (see [40] Ch. 13).

**Lemma 2.14.** Let $g = \prod_{\alpha \text{isotropic}} h_\alpha \in S(h)$, where $h_\alpha \in h$ is defined by the property $h_\alpha(\mu) = \langle \mu, \alpha \rangle$. Then:

1. $\mathbb{C} + g S(h)^W \subset I(h) \subset S(h)^W$.
2. $I(h)_g = S(h)_g^W \supset S(h)^W$.

where $I(h)_g$ and $S(h)_g^W$ denote respectively the localizations of $I(h)$ and $S(h)$ at the set $G := \{g^k \mid k \geq 0\}$.

**Proof.** (1). Clearly $\mathbb{C} \subset I(h)$ and any easy check shows that $g S(h)^W$ is a subalgebra contained in $I(h)$. Since $I(h)$ is a subalgebra we have (1). As for (2), it follows from the inclusions in (1) by noticing that the localization at $G$ is the same for $\mathbb{C} + g S(h)^W$ and $S(h)^W$. ■

We now introduce the *infinitesimal character*
\[
\chi_\lambda : Z(g) \rightarrow \mathbb{C}
\]
defined as $\chi_\lambda(z) = (\beta(z))(\lambda + \rho)$, where $\beta$ is the Harish-Chandra isomorphism.

**Proposition 2.15.** Let $\lambda$ be typical. Then $\chi_\lambda = \chi_\mu$ implies $\mu = s.\lambda$ for some $s \in W$.

**Proof.** The infinitesimal character $\chi_\lambda$ may be thought (via the HC isomorphism) as defined on $I(h)$ since $Z(g) \cong I(h)$, by Theorem 2.13. Since $\lambda$ is typical, we have $\chi_\lambda(g) \neq 0$, hence we may extend (uniquely) $\chi_\lambda$ to $I(h)_g = S(h)_g^W \supset S(h)^W$. Hence $\chi_\lambda = \chi_\mu$ on $S(h)^W$. This implies $\mu = s.\lambda$ (from classical considerations, see, for example, [33], Ch. 5). ■

We now approach the proof of 2.12 with some lemmas.

**Lemma 2.16.** Let $\lambda$ be the highest weight as in 2.12 and let $\mu$ be a maximal weight of $U^\lambda$ with respect to the admissible system $P = P_k \coprod P_n$. Then
\[
(2.6) \quad P^- = P_k \coprod -P_n
\]
is also a positive system and $\lambda > \mu$ with respect to $P^-_0$.

**Proof.** The fact $P^-$ is a positive system comes from the fact that $P^- = -s_0 P$, for $s_0$ the longest element in $W_k$. In fact $-s_0(P) = -s_0(P_k) \coprod -s_0(P_n)$ and $-s_0(P_k) = P_k$, while $-s_0(P_n) = -P_n$. This is because $P$ is chosen admissible, hence the roots in $P_n$ represent the weights of the adjoint representation of $\mathfrak{k}$ on $p^+$, hence they are permuted by the action of $W_k$ the Weyl group of $\mathfrak{k}$.

Now we turn to the second statement. Let $v_\lambda$ and $v_\mu$ maximal vectors with weight $\lambda$ and $\mu$ respectively. Hence $z \in Z(g)$ acts as multiplication by the scalars $\chi_\lambda(z)$ and $\chi_\mu(z)$.
respectively. Since \( v_\lambda \) is the highest weight vector, \( z \) acts as \( \chi_\lambda(z) \) on the whole \( U^\lambda \). Hence the two scalars \( \chi_\lambda(z) \) and \( \chi_\mu(z) \) have to be the same (since \( U(\mathfrak{g})v_\mu \) is a submodule of \( U^\lambda \)).

Then, by the previous lemma \( s.\lambda = \mu \), that is \( \mu + \rho = s(\lambda + \rho) \), for \( s \in W \). Since the hypothesis of \( 2.12 \) guarantee that \( \lambda + \rho \) is dominant with respect to \( P^- \), by usual facts on groups of reflections (see [46] Appendix to Ch. 4) we have that \( \lambda - \mu = \lambda + \rho - s(\lambda + \rho) \) is sum of simple roots, but since \( \lambda - \mu \) is even, it will be the sum of simple roots of \( P^+_0 \). ■

We now make some remarks on the simple systems of \( P \) and \( P^- \). Let

\[
S_0 = \{\alpha_1, \ldots, \alpha_A, \beta_1, \ldots, \beta_B\}
\]

be the simple system for \( P_0 \subset P \) (\( P_0 \) the positive admissible even system contained in \( P \)). We denote by \( \alpha_i \) the compact roots and by \( \beta_j \) the non-compact (even) roots.

Let us now consider \( S \) a simple system for \( P \). Our simple system \( S \) is then written as:

\[
S = \{\alpha_1, \ldots, \alpha_a, \beta_1, \ldots, \beta_B, \gamma_1, \ldots, \gamma_c\}
\]

where the \( \gamma_i \)'s are simple odd roots, while the number of compact and non-compact roots may change since we have introduced the odd roots, that is \( a \leq A, b \leq B \) in general.

As a word of caution let us notice that \( S_0 \) may not be the even part of \( S \), since in general \( S_0 \not\subseteq S \).

**Lemma 2.17.** The simple system \( S \) contains the same compact roots as \( S_0 \). In other words \( a = A \).

**Proof.** Let us assume by contradiction that, say, \( \alpha_r \) is not in \( S \). Then \( \alpha_r \) is decomposable, so we can write is as \( \alpha_r = \delta_1 + \delta_2 \), where \( \delta_1, \delta_2 \) are odd (necessarily or otherwise \( \alpha_r \) would be decomposable in the even positive system). But the positive system \( P \) is admissible, and this is not possible by the discussion after Definition 2.5. ■

**Lemma 2.18.** Let \( S_0 \) be the simple system for \( P_0 \) as above. Then

\[
S_0^- = \{\alpha_1, \ldots, \alpha_A, -\beta'_1, \ldots, -\beta'_B\}
\]

is the simple system for the positive system \( P_0^- \) defined by \( 2.6 \) and \( \beta'_i \) are the non-compact roots in \( P_{n,0}^- \), which are the highest weights for the adjoint representation of \( \mathfrak{k} \) on \( \mathfrak{p}_0^+ \) with respect to the positive system \( P \). In particular there exist positive integers \( m_i \) such that \( \beta'_i = \beta_i + \sum_{\alpha_i > 0} m_i \alpha_i \).

**Proof.** This fact is entirely classical. ■

We now go to the proof of the main result.

**Proof.** (Theorem 2.12) Let us assume by contradiction that \( U^\lambda \) has a submodule \( M \). Let \( \mu \) be a maximal weight of such submodule, so we may as well replace \( M \) with the cyclic module generated by a weight vector \( v_\mu \). We start by showing that \( \lambda - \mu \) is a sum of compact roots.

Since \( U^\lambda \) is a highest weight module with respect to \( P \), we have that \( \lambda - \mu \) is sum of simple roots of \( P \). On the other hand, by Lemma 2.16 we also have that \( \lambda - \mu \) is the sum of simple roots of \( P_0^- \)

\[
S_0^- = \{\alpha_1, \ldots, \alpha_A, -\beta'_1, \ldots, -\beta'_B\}
\]

where \( \beta'_i = \beta_i + \sum_{\alpha_i > 0} m_i \alpha_i \) (by Lemma 2.18).
Hence we can write:

\[ \lambda - \mu = \sum_{i=1}^{A} a_i \alpha_i + \sum_{j=1}^{b} b_j \beta_j + \sum_{k=1}^{c} c_k \gamma_k, \quad a_i, b_j, c_k \in \mathbb{Z}_{\geq 0} \]

and

\[ \lambda - \mu = \sum_{i=1}^{A} a_i' \alpha_i - \sum_{j=1}^{B} b_j' \beta_j \quad b'_j \in \mathbb{Z}_{\geq 0} \]

where in the second expression we use \( \beta'_j \) and then we substitute its expression in terms of \( \beta_j \) and compact roots.

By comparing the two expressions we have:

\[ \sum_{i=1}^{A} a''_i \alpha_i + \sum_{l=1}^{b} (b_l + b'_l) \beta_l + \sum_{k=1}^{c} (c_k + \sum_{j=b+1}^{B} b'_j \gamma_k) = 0 \]

where the coefficients are all positive, with the exception of the \( a''_i \)'s.

For \( j = b + 1, \ldots B \) we have:

\[ \beta_j = \sum_{i=1}^{A} m_{ji} \alpha_i + \sum_{k=1}^{c} n_{jk} \beta_k + \sum_{r=1}^{c} p_{jr} \gamma_r \]

If we substitute, we get:

\[ \sum_{i=1}^{A} a''''_i \alpha_i + \sum_{l=1}^{b} (b_l + b'_l + \sum_{j=b+1}^{B} b'_j n_{jl}) \beta_l + \sum_{k=1}^{c} (c_k + \sum_{j=b+1}^{B} b'_j p_{jk}) \gamma_k = 0 \]

where the coefficients are all positive, with the exception of the \( a''''_i \)'s.

Hence we obtain \( b_l = b'_l = c_k = 0 \), that is \( \lambda - \mu \) is the sum of compact roots.

Now we go back to the highest weight vector \( v_\mu \) of the submodule \( M \subseteq \mathcal{U}(\mathfrak{g}) v_\lambda \). \( v_\mu \) is a linear combination of \( X_{-\theta_1} \ldots X_{-\theta_m} v_\lambda \) where each \( \theta_j \) is in \( P \).

\[ \lambda - \mu = \theta_1 + \ldots + \theta_m \]

Writing each \( \theta_j \) as a linear combination of \( \alpha_i (1 \leq i \leq a) \), \( \beta_j (1 \leq j \leq b) \) and \( \gamma_k (1 \leq k \leq c) \) with integer coefficients \( \geq 0 \), and noting that \( \lambda - \mu \) does not involve the \( \beta_j \) and \( \gamma_k \), we conclude that each \( \theta_j \) does not involve any \( \beta_j \) or \( \gamma_k \). In other words, \( v_\mu \in \mathcal{U}(\mathfrak{p}) v_\lambda \). But then \( v_\mu \) must be a multiple of \( v_\lambda \), showing that \( M = U^\lambda \).

2.5. **Super Character.** In this section we compute the character for the universal Harish-Chandra module \( U^\lambda \) described in the previous sections.

Let the notation be as above. If \( M \) is an \( \mathfrak{h} \)-module with finite multiplicities, its character is given by:

\[ \text{ch}(M) = \sum_{\mu \in \mathfrak{h}^*} (\dim V_\mu) e^\mu \]

By Corollary 2.11 we have the \( \mathfrak{h} \)-module isomorphism

\[ U^\lambda \cong \mathcal{U}(\mathfrak{p}^-) \otimes F \]
This implies
\[ \text{ch}(U^\lambda) = \text{ch}(\mathcal{U}(p^-)) \text{ch}(F) \]

We further know that \( \mathcal{U}(p^-) \simeq \mathcal{U}(p^-_0) \otimes \mathcal{Λ}(p^-_1) \), as \( \mathfrak{h} \)-modules, hence we can immediately write:
\[ \text{ch}(U^\lambda) = \text{ch}(\mathcal{U}(p^-_0)) \text{ch}(\mathcal{Λ}(p^-_1)) \text{ch}(F) \]

Let us quickly recall the following well known expressions
\[ \text{ch}(\mathcal{U}(p^-_0)) = \prod_{\eta \in P_{n,0}} (1 - e^{-\eta})^{-1} = \frac{e^{\rho_{n,0}}}{\Delta_{n,0}} \]
\[ \text{ch}(F) = \frac{\sum_{s \in W_k} \epsilon(s) e^{s(\lambda + \rho_{k,0})}}{\epsilon(s) e^{s(\lambda + \rho_{k,0})} - \Delta_{k,0}} = \frac{\sum_{s \in W_k} \epsilon(s) e^{s(\lambda + \rho_{k,0})}}{\Delta_{k,0}} \]

where \( \epsilon(s) = \det (s) \), and the Weyl denominators are defined as:
\[ \Delta_{n,0} = e^{\rho_{n,0}} \prod_{\eta \in P_{n,0}} (1 - e^{-\eta}) \]
\[ \Delta_{k,0} = e^{\rho_{k,0}} \prod_{\eta \in P_{k,0}} (1 - e^{-\eta}) \]

where
\[ \rho_{n,0} = \frac{1}{2} \sum_{\alpha \in P_{n,0}} \alpha, \quad \rho_{k,0} = \frac{1}{2} \sum_{\alpha \in P_{k,0}} \alpha. \]

and \( P_{n,0}, P_{k,0} \) correspond respectively to the non-compact and compact roots in the (admissible) positive system \( P_0 \) of \( \mathfrak{g}_0 \). Hence:
\[ \text{ch}(F) \text{ch}(\mathcal{U}(p^-_0)) = \left( \sum_{s \in W_k} \epsilon(s) e^{s(\lambda + \rho_{k,0})} \right) \frac{e^{\rho_{n,0}}}{\Delta_{k,0}} = \sum_{s \in W_k} \epsilon(s) \frac{e^{s(\lambda + \rho_{k,0}) + \rho_{n,0}}}{\Delta_{k,0}\Delta_{n,0}} \]

(for the classical expression of \( \text{ch}(F) \), see, for example, \([46, \text{Ch.4}]\)). Notice that for each \( s \in W_k, s(\lambda + \rho_{k,0}) + \rho_{n,0} = s(\lambda + \rho_{k,0} + \rho_{n,0}) \), hence we write:
\[ \text{ch}(F) \text{ch}(\mathcal{U}(p^-_0)) = \sum_{s \in W_k} \epsilon(s) \frac{e^{s(\lambda + \rho_0)}}{\Delta_0} \]

where \( \rho_0 = (1/2) \sum_{\alpha \in P_0} \alpha \) and \( \Delta_0 = \Delta_{k,0}\Delta_{n,0} \).

We now compute \( \text{ch}(\mathcal{Λ}(p^-_1)) \).
\[ \text{ch}(\mathcal{Λ}(p^-_1)) = \prod_{\eta \in P_{1,n}} (1 + e^{-\eta}) \]

where \( P_{1,n} \) are all the positive non-compact roots. Notice that in a PBW basis the odd variables appear at most with degree one. Hence:
\[ \text{ch}(U^\lambda) = \sum_{s \in W_k} \epsilon(s) \frac{e^{s(\lambda + \rho_0)}}{\Delta_0} \prod_{\eta \in P_{1,n}} (1 + e^{-\eta}) \]
3. Preliminaries on supergeometry

In this section we discuss few facts of supergeometry, we need in the following. We refer the reader for a complete basic treatment of this subject to [8], [34], [36], [38], [47]. We are interested in the analytic category of supermanifolds, both real and complex, denoted by \((\text{smflds})_\mathbb{R}\) and \((\text{smflds})_\mathbb{C}\) respectively, or by \((\text{smflds})\) when the statement holds in both categories.

**Definition 3.1.** Let \(M = (\tilde{M}, \mathcal{O}_M)\) and \(N = (\tilde{N}, \mathcal{O}_N)\) be connected supermanifolds, i.e. their reduced spaces \(\tilde{M}\) and \(\tilde{N}\) are connected. Suppose \(\pi: M \rightarrow N\) is a morphism such that

1. \(\tilde{\pi}: \tilde{M} \rightarrow \tilde{N}\) is surjective and is a covering map;
2. for each \(x \in \tilde{N}\) we may choose an open submanifold \(\tilde{U} \subseteq \tilde{N}\), \(x \in \tilde{U}\), such that \(\tilde{\pi}^{-1}(\tilde{U}) = \bigsqcup \tilde{V}_i\), where each \(\tilde{V}_i \rightarrow \tilde{U}\) is an analytic isomorphism; furthermore if \(V_i\) is the open subsupermanifold of \(N\) defined by \(\tilde{V}_i\), then, for each \(i\), \(\pi|_{V_i}: V_i \rightarrow U\) is an analytic isomorphism;

then we say that \((M, \pi)\) is a covering space of \(N\).

**Remark 3.2.** If \(\pi: M \rightarrow N\) is a covering, then \(\tilde{\pi}: \tilde{M} \rightarrow \tilde{N}\) is a covering. Moreover, if \(\tau: M \rightarrow N\) is a morphism, it is a covering map if (and only if) \(\tilde{\tau}: \tilde{M} \rightarrow \tilde{N}\) is a covering map, \(\dim M = \dim N\) and \(d\pi\) is surjective everywhere on \(M\).

Suppose that \(G\) is a SLG. We denote with \(G_e\) the subsuperLiegroup (subSLG for short) of \(G\) whose reduced space is the identity component of \(G\). (For the relevant notions about quotients see [7] and also [8]).

**Lemma 3.3.** Suppose \(G\) is an analytic connected SLG and \(A \subseteq G\) is a closed analytic subSLG of \(G\), \(A_e\) its identity component. Then, in the commutative diagram

\[
\begin{array}{ccc}
G & \longrightarrow & G/A \\
\downarrow & & \downarrow \\
G/A_e & \rightarrow & \\
\end{array}
\]

the map \(G/A_e \rightarrow G/A\) is a covering morphism. Moreover

1. if \(D\) is the discrete even group \(A/A_e\) (note that \(A_e\) is open and normal in \(A\)), it acts (from the right) on \(G/A_e\) and commutes with the projection \(G/A_e \rightarrow G/A\), acting transitively on the fibers.
2. if we work over \(\mathbb{R}\) and either \(G/A\) or \(G/A_e\) has a complex structure compatible with the real analytic structure, the other can be equipped with a unique complex structure compatible with the real analytic structure, such that \(G/A_e \rightarrow G/A\) is a complex analytic morphism and so a covering map of the complex supermanifolds.

**Remark 3.4.** It follows from the above that if \(B\) is a subSLG of \(G\) such that \(B_e = A_e\), then the existence of a complex structure on \(G/B\), \(G\)-invariant and compatible with the real analytic one, implies the existence of such a complex structure on \(G/A_e\) and hence on all the \(G/C\) with \(C_e = A_e\). Moreover, if \(B \subset C\), \(G/B \rightarrow G/C\) is a covering map for the complex structures.
Remark 3.5. If $M$ and $N$ are real analytic supermanifolds and $\pi: M \to N$ is a covering map, then a complex structure on $N$ can be lifted to one on $M$ in an obvious fashion. In general, to push down a complex structure from $M$ to $N$ is more complicated, however in the situation considered above, we can do it, since there is a discrete even group acting as a group of super isomorphisms on $M$, commuting with $\pi$, acting transitively on the fibers of $\pi$.

We first notice that at the topological point $(e, e)$, the map $\alpha: A_1 \times A_2 \to M$ is a submersion at $(e, e)$. For proving 2., note that $\text{Lie}(A_1) + \text{Lie}(A_2) = \text{Lie}(M)$, we have that $\alpha$ is an analytic super isomorphism of $A_1 \times A_2$ with $A_1 A_2$.

We first notice that at the topological point $(e, e) \in A_1 \times A_2$ ($e$ denoting the identity element),

$$(d\alpha)_{(e, e)}(X_1, X_2) = (di_1)_e(X_1) + (di_2)_e(X_2)$$

Since $i_1$ and $i_2$ are injective immersions and $\text{Lie}(A_1) + \text{Lie}(A_2) = \text{Lie}(M)$, we have that $\alpha$ is a submersion at $(e, e)$. For proving that $\alpha$ is a submersion at any $(\overline{a}_1, \overline{a}_2) \in \tilde{A}_1 \times \tilde{A}_2$, it is enough to notice that the diagram

$$
\begin{array}{ccc}
A_1 \times A_2 & \xrightarrow{\alpha} & G \\
\downarrow t & & \downarrow s \\
A_1 \times A_2 & \xrightarrow{\alpha} & G
\end{array}
$$

is commutative, where $t$ and $s$ are given by $t = \ell(\overline{a}_1) \times r(\overline{a}_2)$, $s = \ell(\overline{a}_1) \circ r(\overline{a}_2)$, $\ell$, $r$ being left and right translations.

For proving 2., note that $\text{Lie}(\tilde{A}_1) \cap \text{Lie}(\tilde{A}_2) = \{0\}$, hence $\text{Lie}(M) = \text{Lie}(\tilde{A}_1) \oplus \text{Lie}(\tilde{A}_2)$.

As $\tilde{A}_1 \cap \tilde{A}_2 = \{e\}$, $\tilde{\alpha}$ is an analytic isomorphism. Since $\text{Lie}(A_1) + \text{Lie}(A_2) = \text{Lie}(M)$, and
Lie(\(A_1\)) \cap Lie(\(A_2\)) = \{0\}, \dim(\(A_1 \times A_2\)) = \dim M. So \(\alpha\) is a covering map. As \(\tilde{\alpha}\) is an isomorphism, so is \(\alpha\).

Let us come to 3. The statements are clear at the reduced level. Hence, for transitivity of \(A_1\) on \(A_1A_2/A_2\), we must show that \(d\pi_e(\text{Lie}(A_1)) = T_{\pi(e)}(A_1A_2/A_2)\). But \(d\pi_e(\text{Lie}(A_1)) = \{0\}\) from the theory of quotient spaces, which also gives \(d\pi_e(\text{Lie}(A_1A_2)) = T_{\pi(e)}(A_1A_2/A_2)\). Hence, as \(\text{Lie}(A_1) + \text{Lie}(A_2) = \text{Lie}(A_1A_2)\), we must have \(d\pi_e(\text{Lie}(A_1)) = T_{\pi(e)}(A_1A_2/A_2)\).

To find the stabilizer at \(\pi(e)\) of the action of \(A_1\) on \(A_1A_2/A_2\), let \(N\) be the stabilizer. Clearly \(\tilde{N} = \tilde{A}_1 \cap \tilde{A}_2\). Since the kernel of \(d\pi_e\) is \(\text{Lie}(A_2)\), the kernel of \(d\pi_e\) (where \(\pi' = \pi|_N\)) is precisely the space of those vectors in \(T_e(A_2)\) which are tangent to \(A_1\) at \(e\), namely \(T_e(A_1) \cap T_e(A_2) \simeq \text{Lie}(A_1) \cap \text{Lie}(A_2)\). So \(N = A_1 \cap A_2\).

If \(X\) is a complex supermanifold, let us denote with \(X^R\) its underlying real supermanifold (see [14] [10]).

**Lemma 3.7.** Let \(G\) be a connected complex matrix Lie supergroup, \(\text{Lie}(G) = \mathfrak{g}\). Let \(G_r\) be a connected real form of \(G\), \(\text{Lie}(G_r) = \mathfrak{g}_r\), so that \(\mathfrak{g}\) is the complexification of \(\mathfrak{g}_r\). Let \(R\) be a closed subsupergroup of \(G_r\), \(\text{Lie}(R) = \mathfrak{r}\).

Let \(\mathfrak{q}\) be a complex Lie subsuperalgebra of \(\mathfrak{g}\) such that

- \(\mathfrak{g}_r + \mathfrak{q}^R = \mathfrak{g}^R\);
- \(\mathfrak{g}_r \cap \mathfrak{q}^R = \mathfrak{r}\).

where \(\mathfrak{q}^R\) and \(\mathfrak{g}^R\) are the complex Lie superalgebras \(\mathfrak{q}\) and \(\mathfrak{g}\) viewed as real Lie superalgebras.

Assume that the analytic subSLG \(Q\) defined by \(\mathfrak{q}\) in \(G\) is closed. Let \(R_1\) be the SLG with reduced group \(\tilde{Q} \cap \tilde{G}_r\) and \(\text{Lie}\) superalgebra \(\mathfrak{r}\).

1. \(G_rQ^R\) is an open subsupermanifold of \(G^R\). Hence, \(\tilde{G}_rQ := (\tilde{G}\tilde{Q}, O_{\tilde{G}|\tilde{G}\tilde{Q}})\) is an open subsupermanifold of the complex supergroup \(G\). If \(\pi\) is the natural map \(G \to G/Q\), \(M := \pi(G_rQ)\) is an open subsupermanifold of the complex supermanifold \(G/Q\). We also write \(\tilde{M} = G_rQ/Q\).

2. The natural action of \(G_r\) on \(M^R\) is transitive; if its stabilizer at \(\pi(e)\) is \(R_1\), then \(G_r/R_1 \simeq M^R\). Hence \(G_r/R_1\) acquires naturally a complex supermanifold structure.

3. If \(R'\) is any closed subSLG of \(G_r\) with \(\text{Lie}(R') = \mathfrak{r}\), then \(G_r/R'\) acquires a natural \(G_r\)-invariant complex (super) structure, compatible with the real analytic one.

**Proof.** 1. By our hypothesis \(G_r\) and \(Q^R\) are subsupergroups of \(G^R\) such that \(\mathfrak{g}_r + \mathfrak{q}^R = \mathfrak{g}^R\). Hence by Lemma 3.6 we are done. 2. Immediate from 3. of Lemma 3.6. 3. Follows from Remark 3.4.

### 3.1. Associated Super Vector Bundles and Super Fréchet Representations

For the relevant material about super vector bundles we refer to [14]. Here we recall that a super vector bundle \(\mathcal{V}\) of rank \(p|q\) on a supermanifold \(M\) is a locally free sheaf of rank \(p|q\) over \(\tilde{M}\), that is for each \(x \in \tilde{M}\), there exist \(U\) open such that \(\mathcal{V}(U) \cong \mathcal{O}_M(U)^{p|q} := \mathcal{O}_M(U) \otimes k^{p|q}\). \(\mathcal{V}\) is a sheaf of \(\mathcal{O}_M\) modules and at each \(x \in \tilde{M}\), the stalk \(\mathcal{V}_x\) is a \(\mathcal{O}_{M,x}\)-module. We define the fiber of \(\mathcal{V}\) at the point \(x\) as the vector superspace \(\mathcal{V}_x/m_x\mathcal{V}_x\), where \(m_x\) is the maximal ideal of \(\mathcal{O}_{M,x}\).
We briefly recall the definition of associated super vector bundle in the language of SHCP. These are super vector bundles on $G/H$ associated to finite dimensional $H$-representations, where $H$ is a closed subSLG of $G$.

**Definition 3.8.** Let $G$ be a SLG, $H$ a closed subSLG, $\sigma$ a finite finite-dimensional complex representation of $H$ on $V$, with $\sigma = (\tilde{\sigma}, \rho^{\sigma})$ in the language of SHCP’s. Consider the sheaf over $\tilde{G}/\tilde{H}$

$$A(U) := O_G(p^{-1}(U)) \otimes V, \quad U \subset \tilde{G}/\tilde{H}$$

where $p : G \to G/H$ is the canonical projection. We define the super vector bundle associated with $\sigma$ as

$$U \mapsto \mathcal{A}_{SHCP}(U)$$

where:

$$\mathcal{A}_{SHCP}(U) := \left\{ f \in \mathcal{A}(U) \mid \left\{ \begin{array}{l} (r^*_h \otimes 1)f = (1 \otimes \tilde{\sigma}(h)^{-1})(f) \quad \forall h \in \tilde{H} \\ (D_X^R \otimes 1)f = (1 \otimes \rho^{\sigma}(-X))f \quad \forall X \in h_1 \end{array} \right. \right\}$$

One can prove that the previous definition defines a super vector bundle over $G/H$ with typical fiber $V$.

The following definition is a natural generalization of the one given in [12], and it can be found in [1]. We refer to [50] for the classical result.

**Definition 3.9.** Let $G$ be a complex or real Lie supergroup. We say we have a representation of $G$ in the complex Fréchet vector superspace $F$ if:

- $\tilde{G}$ acts on $F = F_0 \oplus F_1$ and:
  $$\tilde{\pi} : \tilde{G} \to \text{Aut}(F_0) \times \text{Aut}(F_1)$$
  is an ordinary Fréchet representation preserving parity.
- Denote with $C^{\text{End}}(C^\infty(\tilde{\pi}))$ the algebra of continuous linear endomorphisms of the space of smooth vectors of $C^\infty(\tilde{\pi})$ endowed with the Fréchet relative topology inherited from $C^\infty(\tilde{G}; F)$. There is an even linear map
  $$\rho^{\tilde{\pi}} : \mathfrak{g} \to C^{\text{End}}(C^\infty(\tilde{\pi}))$$
  such that
  $$\begin{align*}
  (1) \quad &\rho^{\tilde{\pi}}|_{\mathfrak{g}_0} = d\tilde{\pi} \\
  (2) \quad &\rho^{\tilde{\pi}}([X,Y]) = \rho^{\tilde{\pi}}(X)\rho^{\tilde{\pi}}(Y) - (-1)^{|X||Y|} \rho^{\tilde{\pi}}(Y)\rho^{\tilde{\pi}}(X) \\
  (3) \quad &\rho^{\tilde{\pi}}(\text{Ad}(g)X) = \tilde{\pi}(g)\rho^{\tilde{\pi}}(X)\tilde{\pi}(g)^{-1}
  \end{align*}$$

We have: $F^\infty = F_0^\infty \oplus F_1^\infty$.

It is not difficult to prove the following proposition.

**Proposition 3.10.** Let $G$ and $H$ be as above. Let $\sigma = (\tilde{\sigma}, \rho^{\sigma})$ be an $H$-representation in the language of SHCP. If $U \subset \tilde{G}/\tilde{H}$ is a $G$-invariant open subset. The assignment:

$$\begin{align*}
(1) \quad &\tilde{G} \times \mathcal{A}^{\sigma}(U) \to \mathcal{A}^{\sigma}(U), \quad g, f \mapsto l^{*}_{g^{-1}}f \\
(2) \quad &\mathfrak{g} \to \text{End}(\mathcal{A}^{\sigma}(U)), \quad X \mapsto D^R_{X}
\end{align*}$$

gives a representation of $G$ on the Fréchet superspace $\mathcal{A}^{\sigma}(U)$, where as usual $D^R_{X} = (1 \otimes X)\mu^{*}$ and the element $X \in \mathfrak{g}$ is interpreted as a left invariant vector field.
We now turn to examine the decomposition of a super Fréchet representations of a supergroup with respect to the action of an ordinary compact Lie subgroup.

Let $H$ be a real Lie supergroup, and $U$ an ordinary compact Lie subgroup in $H$, $T \subset U$ a maximal torus. Notice that the following treatment applies also to the case $T = U$.

Assume $H$ acts on a Fréchet superspace $F$ via the representation $R$ according to Definition 3.9. Notice that the restriction of the representation $R$ to $U$ automatically preserves the $\mathbb{Z}_2$-grading $F = F_0 \oplus F_1$. Let $\tau$ be a character of an irreducible representation of $U$, that we can assume unitary. We define the operator:

$$P(\tau) = d(\tau) \int_U \tau(k)^{-1} R(k) dk,$$

where $d(\tau)$ is the degree of $\tau$ (namely the dimension of the irreducible representation associated with $\tau$). We define $F(\tau)$ as the closed subspace of $F$ stable under $U$ and on which $U$ acts irreducibly according to the irreducible representation with character $\tau$. $F(\tau)$ is called the isotypic subspace corresponding to the character $\tau$.

We stress that, in the whole section, $F^\infty = F_0^\infty \oplus F_1^\infty$ denotes the space of smooth vectors for the representation $R$ of $H$. When we want to consider smooth vectors for the restriction of $R$ to a subgroup $U$ of $G$ we will add a subscript $F^\infty_U$. Clearly, one has $F^\infty \subseteq F^\infty_U$. The following is a standard result, see [26] or [50, Sections 4.4.2 and 4.4.3].

**Proposition 3.11.** Let $R$ be a representation of the compact Lie group $U$ on the Fréchet superspace $F = F_0 \oplus F_1$. Then:

1. the operator $P(\tau)$ defined by (6), is an even continuous projection onto the isotypic subspace $F(\tau) = F(\tau)_0 \oplus F(\tau)_1$.
2. $F(\tau)$ is a closed subsuperspace of $F$ and it consists of the algebraic sum of the linear subsuperspaces on which $U$ acts irreducibly according to the (irreducible) representation with character $\tau$. Furthermore the $F(\tau)$ are linearly independent.
3. $P(\tau)P(\tau') = 0$, if $\tau \neq \tau'$.
4. $P(\tau)$ commutes with the $U$ action and with any continuous endomorphism of $F$ commuting with $U$.
5. On the space of smooth vectors we have $\sum_{\tau} P(\tau) = \text{id}_{|_{F^\infty}}$, that is any $f \in F^\infty$ is expressed as $\sum_{\tau} f(\tau)$, which is called the Fourier series of $f$. Furthermore, such series converges uniformly.
6. Let $F^0 := \sum F(\tau)$ (algebraic sum). Then $F^0 \subset F^\infty$ and both are dense in $F$.

When necessary we shall stress the fact that the decomposition of $F$ is under the $U$-action by writing $F^0_U$ and $F^0_U(\tau)$, similarly we write $P^0_U(\tau)$ for the operator defined in (6).

**Definition 3.12.** We say that a representation $R$ as above is $U$-finite if every $F(\tau)$ is finite dimensional.

The following is a standard lemma, that we leave to the reader as an exercise.

**Lemma 3.13.** Let the notation and setting be as above.

1. Let $\hat{F}^0 = \sum_{\tau} L_\tau$ be a dense subspace in $F$, where the sum is algebraic, the subspaces $L_\tau$ are all finite dimensional and $L_\tau \subset F^0_U(\tau)$. Then $L_\tau = F^0_U(\tau)$ for all $\tau$ and $\hat{F}^0 = F^0_U \subset F^\infty$. Hence, $F$ is $U$-finite.
(2) Let $U'$ be a compact subgroup of $U$ and assume that $F$ is $U'$-finite. Then $F$ is also $U$-finite and $F_U^0 = F_{U'}^0$.

4. REPRESENTATIONS OF THE SUPERGROUP

The objective of this section is to construct representations of a real supergroup $G_r$ which correspond infinitesimally to the highest weight Harish-Chandra modules.

Let $\mathfrak{g}$ be as in list (1) and let $\mathfrak{g}_r$ be a real form of $\mathfrak{g}$ (see [12, 9]). By the ordinary theory, we know that, since $\mathfrak{g}_0$ is either semisimple or with a one-dimensional center, the simply connected corresponding ordinary Lie group $\tilde{G}$ is a matrix Lie and algebraic group. Then, the SHCP $G = (\tilde{G}, \mathfrak{g})$ (see [8] Ch. 11 and [17]) can be viewed either as an algebraic or an analytic complex SHCP. Hence $G$ is a complex analytic matrix supergroup and $G^R$, the supergroup $G$ viewed as a real supergroup (see [14, 10]), is also a real analytic matrix supergroup. Let $G_r$ be the real analytic supergroup corresponding to the real subsuperalgebra $\mathfrak{g}_r$ of $\mathfrak{g}^R$ (the superalgebra $\mathfrak{g}$ viewed as real superalgebra). Also $G_r$ is a matrix real Lie supergroup and we will refer to $G$ as the complexification of $G_r$ and we will refer to $G_r$ as a real form of $G$.

Fix $\mathfrak{h}$ and $\mathfrak{h}_r$ CSA of $\mathfrak{g}$ and $\mathfrak{g}_r$, respectively, $\mathfrak{h}$ the complexification of $\mathfrak{h}_r$. $K_r = \widetilde{K}_r$ is the maximal compact in $\tilde{G}_r$, $A_r = A_r$ the (ordinary) torus, $A_r \subset G_r$, while $\mathfrak{t}_r$, $\mathfrak{h}_r$ the respective Lie superalgebras. We drop the index $r$ to mean the complexifications. We assume:

$$\mathfrak{h} \subset \mathfrak{t} \subset \mathfrak{g}, \quad \mathfrak{h}_r \subset \mathfrak{t}_r \subset \mathfrak{g}_r.$$ 

Hence our CSA $\mathfrak{h} = \mathfrak{h}_0$. Let $\Delta$ be the root system corresponding to $(\mathfrak{g}, \mathfrak{h})$ and fix $P$ a positive system. Let us define $\mathfrak{b}^\pm$ and $\mathfrak{n}^\pm$ the Borel and nilpotent subsuperalgebras:

$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in \Delta} \mathfrak{g}_\alpha, \quad \mathfrak{b}^\pm := \mathfrak{h} \oplus \sum_{\alpha \in \pm P} \mathfrak{g}_\alpha, \quad \mathfrak{n}^\pm := \sum_{\alpha \in \pm P} \mathfrak{g}_\alpha.$$ 

We call $\mathfrak{B}^\pm$ Borel subsupergroup and $\mathfrak{N}^\pm$ unipotent subsupergroup, their corresponding analytic Lie supergroups in $G$. In particular, $\mathfrak{B}^\pm$ and $\mathfrak{N}^\pm$ are connected and are algebraic subsupergroups of $G$.

4.1. MAXIMAL TORUS AND BIG CELL IN LIE SUPERGROUPS OF CLASSICAL TYPE. In this section we want to study the connected ordinary Lie group $A \subset G$, called a maximal torus of $G$, with associated Lie algebra $\text{Lie}(A) = \mathfrak{h}$ the CSA of $\mathfrak{g}$, and its relation with the supergroups $\mathfrak{N}^\pm$. In particular we introduce the supermanifold $\Gamma := \mathfrak{N}^- \mathfrak{A} \mathfrak{N}^+ \subset G$, called the big cell, which plays a key role in what follows. We observe first that the (ordinary) torus $A$ normalizes $\mathfrak{N}^\pm$, as it happens for the ordinary setting.

**Proposition 4.1.** Let $\mathfrak{m}_r$ be a real form of the Lie superalgebra $\mathfrak{g} = \text{Lie}(G)$ containing $\mathfrak{h}_r$ the CSA of $\mathfrak{g}_r$. Then: $\mathfrak{m}_r + \mathfrak{b}^+ = \mathfrak{g}$ and in particular $M_r(B^+)^R$ is open subsupermanifold of $G^R$, where $M_r$ is the connected subSLG of $G$, determined by $\mathfrak{m}_r$.

**Proof.** Since $\mathfrak{m}_r$ is a real form of $\mathfrak{g}$, we have $\mathfrak{g} = \mathfrak{m}_r \oplus i\mathfrak{m}_r$. This is equivalent to say that there exists an antilinear involution $\sim: \mathfrak{g} \to \mathfrak{g}$ whose set of fixed points is $\mathfrak{m}_r$. Moreover, since $\mathfrak{h}_r$ is contained in $\mathfrak{t}_r$, we have that all the roots are imaginary when restricted to $\mathfrak{h}_r$. These facts imply that $\mathfrak{g}_\alpha = \mathfrak{g}_{-\alpha}$. 

In order to prove our statement it is enough to show that $X_{-a}$ and $iX_{-a}$ belong to $m_r + n^+$. We have that:

$$X_{-a} = X_a = (X_a + X_a^-) - X_a \in m_r + n^+
$$

$$iX_{-a} = -iX_a^- = (-iX_a^- + iX_a) - iX_a \in m_r + n^+
$$

Hence, by Lemma 3.6, we obtain our result.

**Proposition 4.2.** Let the notation be as above. Then we have that:

1. $\tilde{\Gamma} := N^-A N^+ $ is open in $\tilde{G}$.

2. $\tilde{A}, \tilde{N}^\pm$ are closed and $\tilde{N}^\pm \cap \tilde{A} = \{1\}$.

3. The morphism $N^- \times A \times N^+ \longrightarrow G, \ (n^-,h,n^+) \longmapsto n^-h n^+$, $n \in N^\pm(T)$, $h \in A(T),\ T \in (\text{smflds})_C$ is an analytic isomorphism onto its image $N^-A N^+$ which is an open subsupermanifold of $G$.

**Proof.** (1) and (2) are statements of ordinary geometry. (3) Consider the morphism $\phi : A \times N^+ \longrightarrow AN^+ \subset G$. $AN^+$ is a Lie supergroup, since $N^+$ is normalized by $A$ and $\text{Lie}(AN^+) = h + n^+$. Hence $\phi$ is a diffeomorphism onto its image (apply Lemma 3.6). We now apply again Lemma 3.6 to the map $\psi : N^- \times AN^+ \rightarrow G$. $\psi$ is a diffeomorphism onto its image, which is an open subsupermanifold of $G$.

**Remark 4.3.** The image of the multiplication morphism $A \times N^+ \longrightarrow AN^+ \subset G$ is a Lie supergroup. Since its reduced space is $\tilde{B}^+ = \tilde{A}N^+$ and its Lie superalgebra $b^+ = h \oplus n^-$, we have that $B^+ = AN^+$ (and similarly $B^- = AN^-$), where $B^+$ is the unique connected subsupergroup of $G$ with Lie superalgebra $b^+$.

**Definition 4.4.** Let the notation be as above. We define the big cell in $G$ as the open subsupermanifold of $G$:

$$\Gamma := N^-A N^+ \subset G$$

Its underlying topological space $\tilde{\Gamma} = N^-A N^+$ is open and dense in $G$.

**Proposition 4.5.** Let the notation be as above. Then we have that:

1. $G_r(B^\pm)^R$ are open real subsupermanifolds in $G^R$; $G_rB^\pm = (\tilde{G}_r\tilde{B}^\pm, O_{G_r\tilde{B}^\pm})$ are open complex subsupermanifolds in $G$.

2. $G_r/A_r \cong G_rB^\pm/B^\pm$ acquires a $\tilde{G}_r$ invariant complex structure.

3. $N^-$ is a section for $\Gamma \rightarrow \Gamma/B^+$, the left action of $A$ reads:

$$A \times \Gamma/B^+ \longrightarrow \Gamma/B^+, \ (h,nB^+(T)) \longmapsto hnh^{-1}B^+(T), \ n \in N^\pm(T), \ h \in A(T), \ T \in (\text{smflds})_C$$

**Proof.** (1) Due to Lemma 3.6, $g_r + b^\pm = g_r$, hence the map $\alpha : G_r \times B^\pm \rightarrow G$ is a subsupermersion and the subsupermanifolds $G_r(B^\pm)^R$ are open in $G^R$.

(2) If we prove that $g_r \cap b^\pm = h_r$ and $\tilde{G}_r \cap \tilde{B}^+ = \tilde{A}_r$, we can apply Lemma 3.7 and conclude. Let us hence proceed to prove these facts. We have

$$g_r \cap b^\pm = h_r.$$
Indeed, let $X \mapsto X^\sigma$ be the conjugation of $\mathfrak{g}$ associated with $\mathfrak{g}_r$, as described in the proof of Prop 4.1. Consider the case of $\mathfrak{b}^+$ for definiteness. $X \in \mathfrak{b}^+$ can be written as $X = \sum c_i H_i + \sum_{\alpha \in \Delta^+} d_\alpha X_\alpha$ with $H_i \in \mathfrak{h}_r$, $X_\alpha \in \mathfrak{p}_\alpha$, and $c_i, d_\alpha \in \mathbb{C}$. Then $X^\sigma = \sum c_i H_i + \sum_{\alpha \in \Delta^+} d_\alpha X_\alpha$. Since $g_\alpha = g_{-\alpha}$ (see the proof of Prop 4.1), we have that $X^\sigma = X$ if and only if $X \in \mathfrak{h}_r$.

Since by assumption the SLG $G$ is simply connected, there exists an antiautomorphism $\sigma: G \to G$ such that $(d\sigma)_e(X) = X^\sigma$. By the ordinary theory we have that $G_r \cap B^+ = \tilde{A}_r$.

Indeed, let $a = hn^+ \in G_r \cap B^+$, with $h \in \tilde{A}_r$ and $n^+ \in \tilde{B}^+$. Hence $hn^+ = \tilde{\sigma}(h)n^-$ (where $n^- = \tilde{\sigma}(n^+)$), that is $\tilde{\sigma}(h)^{-1}hn^+ = n^-$, so that $h = \tilde{\sigma}(h)$, $n^+ = n^- = 1$, so $a \in \tilde{A}_r$.

(3) Since the big cell $\Gamma \subset G$ is right $B^+$-invariant and open, and the canonical projection $p: G \to G/B^+$ is a submersion, we can define the open subsupermanifold of $G/B^+$:

$$
\Gamma/B^+ := (\Gamma/\tilde{B}^+, \mathcal{O}_{G/B^+}|_{\Gamma/\tilde{B}^+})
$$

We have a $N^-$ equivariant diffeomorphism $N^- \to \Gamma/\tilde{B}^+$, $n^- \mapsto n^+ B^+ (T)$, $n^- \in N^-(T)$, $T \in \text{smflds}_\mathbb{C}$. In fact, by the ordinary theory we have a diffeomorphisms of the underlying differentiable manifolds and the differential at the identity is an isomorphism: $n^- \cong \mathfrak{g}/\mathfrak{b}^+$.

4.2. Line bundles on $G/B^+$. Let us consider a character $\chi_r$ of the classical real maximal torus $A_r$ inside the real supergroup $G_r$. This character uniquely extends to an holomorphic character of $A$ and has the form

$$
\chi: A \to \mathbb{C}^\times
$$

$$
\exp(H) \mapsto e^{\lambda(H)}
$$

for an integral weight $\lambda \in \mathfrak{h}^*$ (i.e. a weight such that $\lambda(H_\gamma) \in \mathbb{Z}$ for all roots $\gamma$).

We can trivially extend the character $\chi$ of $A$ to a character of the Borel subsupergroup $B^+$, since we know $B^+ = AN^+$. We denote with $(\chi_0, \lambda)$ the corresponding representation in the SHCP formalism.

The character $\chi = e^\lambda$ defines according to 4.1 an holomorphic line bundle on $\tilde{G}/\tilde{B}^+$ that we denote with $L^\lambda$ or $L_\lambda$ depending on the convenience. If $p: G \to G/B^+$ we have:

$$
L^\lambda(U) = L_\lambda(U) = \left\{ f \in \mathcal{O}_G(p^{-1}(U)) \mid \begin{cases} r^*_b f = \chi_0(b)^{-1}(f) & \forall b \in \tilde{B}^+ \\ D^\lambda_X f = \lambda(-X) f & \forall X \in \mathfrak{b}^+ \end{cases} \right\}
$$

We can equivalently write:

$$
L^\lambda(U) = L_\lambda(U) = \left\{ f: p^{-1}(U) \to \mathbb{C}^{1|1} \mid f_T(gb) = \chi_T(b)^{-1}f_T(g), b \in B^+(T), g \in U(T) \right\}
$$

We now turn our attention to the Frechét superspace $F := L^{\lambda}(\tilde{\Gamma}/\tilde{B}^+)$, where $\Gamma = N^-AN^+$ is the big cell in the complex supergroup $G$. $\Gamma$ is neither stable under $G$-action nor under the $G_r$-action, however, as any neighbourhood of the identity, it is stable under the action of $U(\mathfrak{g})$ and we want to study such representation.

**Proposition 4.6.** The restriction of the holomorphic line bundle $L^\lambda$ to $\tilde{\Gamma}/\tilde{B}^+ = N^-AN^+/B^+$ is trivial:

$$
L^\lambda(\tilde{\Gamma}/\tilde{B}^+) \cong \mathcal{O}_{G/B^+}(\tilde{\Gamma}/\tilde{B}^+)
$$
In particular, there is a canonical identification between:

\[ F = L^x(\Gamma/B^+) \simeq O(N^-) \]

between the sections on the big cell of the line bundle \( L^x \) and the holomorphic functions on \( N^- \).

**Proof.** In order to prove the triviality of the line bundle \( L^x \) over \( \widetilde{\Gamma}/B^+ \), we have to construct a section \( s: \Gamma/B^+ \to \Gamma \). This is the content of Prop. 4.5 (3). The isomorphism (7) is easily established using the correspondence between sections of the associated bundle \( L^x \) and the \( B^+ \)-equivariant mappings \( N^- B^+ \to \mathbb{C}^{1|1} \), as in the classical setting (see, for example, [39]). More precisely, let

\[ \kappa: N^- \times B^+ \xrightarrow{\sim} N^- B^+ \]

be the isomorphism established in Prop. 4.2. We have maps \( \eta: L^x(\widetilde{\Gamma}/B^+) \to O(N^-) \) and \( \zeta: O(N^-) \to L^x(\widetilde{\Gamma}/B^+) \) given by

\[ \eta: L^x(\widetilde{\Gamma}/B^+) \to O(N^-) \]
\[ \zeta: O(N^-) \to L^x(\widetilde{\Gamma}/B^+) \]
\[ f \mapsto G_f \coloneqq \eta(f) \]
\[ G \mapsto f_G \coloneqq \zeta(G) \]

where \( G_f \) and \( f_G \) are the morphisms defined as follows

\[ G_f: N^- \xrightarrow{i} N^- \times B^+ \xrightarrow{\kappa} N^- B^+ \xrightarrow{f} \mathbb{C}^{1|1} \]

and

\[ f_G: N^- B^+ \xrightarrow{\kappa^{-1}} N^- \times B^+ \xrightarrow{G \times \chi} \mathbb{C}^{1|1} \times \mathbb{C} \to \mathbb{C}^{1|1} \]

\( \eta \) and \( \zeta \) gives the desired isomorphism, we leave to the reader the standard checks involved.

**Remark 4.7.** Since the Frechét topology on \( L^x \) is defined through local trivializations, by the previous Proposition we have that the identification \( L^x(\widetilde{\Gamma}/B^+) \simeq O(N^-) \) is also an isomorphism of Frechét superspaces, an in the ordinary case.

To ease the notation we shall also write \( L^x(\Gamma) \) in place of \( L^x(\widetilde{\Gamma}/B^+) \).

Let \( t_\alpha \) denote the global homogeneous exponential coordinates on \( N^- \) (see [35] [23] for the definition of exponential). By a classical result, if \( \widetilde{N} \) is a connected nilpotent Lie group, \( \mathcal{U}(n_0) \) preserves the ordinary polynomials \( \mathcal{P}(\widetilde{N}) \) on \( \widetilde{N} \). Let \( \mathcal{P} = \mathcal{P}(\widetilde{N}) \otimes \wedge(n_1^-) \). We thus have the natural identifications:

\[ \mathcal{P} = \mathcal{P}(\widetilde{N}^-) \otimes \wedge(n_1^-) = \text{Hom}_{n_0}(\mathcal{U}(n^-), \mathcal{P}(\widetilde{N}^-)) \subset \text{Hom}_{n_0}(\mathcal{U}(n^-), \mathcal{C}^\infty(\widetilde{N}^-)) \]

Notice that \( \mathcal{P} \) are the polynomials in the indeterminates \( t_\alpha \).

We now want to study in detail the action of \( A_r \), the ordinary torus in \( G_r \), on the polynomials \( \mathcal{P} \) in \( O(N^-) \) and the corresponding superalgebra \( \mathcal{P}^- \) in \( F = L^x(\Gamma) \).

Proposition 4.6 allows us to obtain immediately the following corollary (we shall also see it later as a consequence of Lemma 4.12 in the next section).

**Proposition 4.8.** \( \mathcal{P} \) is dense in \( O(N^-) \) and \( \mathcal{P}^- \) is dense in \( F \).
Proof. In view of the definition of the topology on $F$, it is enough to prove that $\mathcal{P}$ is dense in $O(N^-)$. The proof goes as in the ordinary setting, since $N^-$ is analytically isomorphic to $\mathbb{C}^m|n$ via the exponential morphism, for suitable $m|n$. ■

4.3. The action of the maximal torus on the polynomials on the big cell. In this section we introduce two natural actions $c$ and $l$ of the ordinary Lie group $A_r$ on the big cell $\Gamma = N^-AN^+$, together with the actions $i$ and $\ell$ they induce on the Frechét superspace $L^x(\Gamma)$. We notice for future reference that both actions coincide on the quotient $\Gamma/B^+$.

In the definition of the two actions we use the isomorphism (see Prop. 4.2)

$$\kappa: N^- \times B^+ \xrightarrow{\sim} \Gamma$$

Let us start with the action $c$ related to the conjugation. Since $A_r$ acts on $N^-$ by conjugation (see Prop. 4.5), we have a global action of $A_r$ on $\Gamma$ defined as:

$$c: A_r \times \Gamma \xrightarrow{1_A \times \kappa^{-1}} A_r \times (N^- \times B^+) \xrightarrow{\text{conj} \times 1_{B^+}} N^- \times B^+ \xrightarrow{\kappa} \Gamma$$

which in the functor of points notation reads

$$a \cdot (n^-b^+) = (an^-a^{-1})b^+, \quad a \in \tilde{A}_r, \quad n^- \in N^-(T), \quad b^+ \in B^+(T).$$

Since $A_r$ also acts on $B^+$ by left translation $l'$, we can define the left action of $A_r$ on $\Gamma$ as

$$l_a = \kappa \circ (\text{conj}_a \times l'_a) \circ \kappa^{-1}$$

or, in the functor of points notation,

$$a \cdot (n^-b^+) = (an^-a^{-1})a \cdot b^+.$$

Both actions commute with right translations by $B^+$ and hence define representations of $A_r$ on $L^x(\Gamma)$

$$i, \ell: A_r \times L^x(\Gamma) \rightarrow L^x(\Gamma)$$

where $i_a(f) = c_{a^{-1}}^*(f)$ and $\ell_a(f) = l_{a^{-1}}^*(f)$ for all $a \in \tilde{A}_r$, and all $f \in L^x(\Gamma)$.

These representations are most easily written in the functor of points notation as

$$i_a(f)(n^-b^+) = f((a^{-1}n^-a)b^+)$$
$$\ell_a(f)(n^-b^+) = f((a^{-1}n^-a^{-1})b^+)$$

The above formulas further simplify using the identification

$$L^x(\Gamma) \simeq O(N^-),$$

we leave the details to the reader.

**Lemma 4.9.** Let the notation be as above. Then

1. $\ell_a f = \chi(a)(i_a f)$
2. $i_a t_\alpha = \chi_a(a)t_\alpha \quad \forall a \in \tilde{A}_r$
Proof. (1) follows immediately from (9). For (2) let \( n = \exp(\sum_{\beta \in P} y_{\beta} X_{\beta}) \) in \( N^{-}(T) \), then the result comes from the following formal calculation:
\[
t_{\alpha}(a^{-1}na) = t_{\alpha}\left( \exp\left(\sum_{\beta \in P} y_{\beta} \text{Ad}(a)X_{\beta}\right)\right) = t_{\alpha}(\exp(\sum_{\beta \in P} y_{\beta}\chi_{\beta}(a)X_{\beta})
= \chi_{\alpha}(a)t_{\alpha}(n),
\]
where \( a \in \widetilde{A}_{r}, y_{\beta} \in \mathbb{C} \) and the \( t_{\alpha} \) are the polynomial coordinates on \( N^{-} \) (see Sec. 4.2).

To ease the notation we shall also write \( a \cdot f \) in place of \( \ell_{a}(f) \).

**Proposition 4.10.** Let \( \mathcal{P} \) be the polynomial superalgebra generated by the \( t_{\alpha} \) in \( \mathcal{O}(N^{-}) \) and let \( \mathcal{P}^{\sim} \) be the corresponding submodule in \( F \). \( A_{r} \) acts on \( \mathcal{P}^{\sim} \) and we have that:
\[
a \cdot \left( t_{\alpha_{1}}^{r_{\alpha_{1}}} \ldots t_{\alpha_{s}}^{r_{\alpha_{s}}} \right)^{\sim} = \chi_{\lambda + \sum_{r_{\alpha_{i}, \alpha_{i}} \in P} m_{\alpha}}(a) \cdot \left( t_{\alpha_{1}}^{r_{\alpha_{1}}} \ldots t_{\alpha_{s}}^{r_{\alpha_{s}}} \right)^{\sim}
\]
Hence \( \mathcal{P}^{\sim} \) decomposes into the sum of eigenspaces \( \mathcal{P}_{d}^{\sim} \) for the action of \( A_{r} \), where \( d \) ranges in \( D^{+} \) the semigroup in \( \mathfrak{h}^{*} \) generated by the positive roots:
\[
\mathcal{P}^{\sim} = \bigoplus_{d \in D^{+}} \mathcal{P}^{\sim}_{d}, \quad \mathcal{P}^{\sim}_{d} = \bigoplus_{r_{\alpha_{i}, \alpha_{i}} = d} \mathbb{C} \cdot \left( t_{\alpha_{1}}^{r_{\alpha_{1}}} \ldots t_{\alpha_{s}}^{r_{\alpha_{s}}} \right)^{\sim}
\]
A similar decomposition holds also for \( \mathcal{P} \).

**Proof.** This is a simple calculation, similar to the one in Lemma 4.9.

**Corollary 4.11.** The maximal torus \( A_{r} \) acts on the Frechét superspace \( L^{x}(\Gamma) \) and we have:

(1) \( F(\tau) \neq 0 \) if and only if \( \tau = \chi_{-\lambda + d} \) for some \( d = \sum_{m_{\alpha} \in \mathbb{Z}_{\geq 0}, \alpha \in P} m_{\alpha} \alpha \).

(2) \[
F(\chi_{\lambda + d}) = \mathcal{P}^{\sim}_{\lambda + d}
\]

and
\[
\dim(F(\chi_{\lambda + d})) = \# \left\{ r = (r_{\alpha}) \mid \sum_{r_{\alpha} \in \mathbb{Z}_{\geq 0}, \alpha \in P} r_{\alpha} \alpha = d \right\}
\]

**Proof.** (1) and (2) are consequences of Lemma 3.13. The computation of the dimension is straightforward.

We now want to prove the fact that the spectrum of \( A_{r} \) remains unchanged when we change the open set we are considering in a suitable way. We shall first prove a general lemma.

Let \( T \) be an ordinary compact torus acting on a finite dimensional complex vector superspace \( V \). By a classical result we have the action of \( T \) on \( V \) is via characters \( \tau \)’s and, with a suitable choice of a basis of \( V \), reads as follows
\[
T \times V \rightarrow V
\]
\[
t, (v_{1}, \ldots, v_{m}, \nu_{1}, \ldots, \nu_{n}) \mapsto (\tau_{1}(t)v_{1}, \ldots, \tau_{m}(t)v_{m}, \tau_{m+1}(t)\nu_{1}, \ldots, \tau_{m+n}(t)\nu_{n})
\]
We can easily transport this action to the space of polynomial functions \( \text{Pol}(V) \) on \( V \) and obtain the following action:
\[
t \cdot \sum a_{ij} z^{I} \xi^{J} = \sum a_{ij} \tau^{I}(t)^{-1} \tau^{J}(t)^{-1} z^{I} \xi^{J}
\]
using the multiindex notation $I = (i_1, \ldots, i_n)$ with possibly repeated indices, $J = (j_1, \ldots, j_n)$ with no repeated indices.

$T$ has also a natural action on the holomorphic sections of the structural sheaf on $V$, $\mathcal{O}_V(U)$, where $U$ is a $T$ invariant open set in $V$. If $g \in \mathcal{O}_V(U)$, we know we can view such $g$ as a morphism $g : U \rightarrow \mathbb{C}^{1|1}$. If $\rho_t(u) := t \cdot u$ is the action of $T$ on $u$, we define:

$$t \cdot g = g \circ \rho_t^{-1}$$

Notice that such action agrees with the previously defined action on the polynomials.

We define $\text{Pol}(\tau)$ the space of polynomials transforming according to the character $\tau$, that is:

$$\text{Pol}(\tau) = \{ p \in \text{Pol}(V) \mid t \cdot p = \tau(t)p \}$$

We define also $\text{Pol}(U) = \text{Pol}(V)\mid_U$, for any open $U \subset V$.

**Lemma 4.12.** Let $T$ be an ordinary compact torus acting on a finite dimensional complex vector superspace $V$. For any character $\tau$ of $T$, we assume that $\dim(\text{Pol}(\tau)) < \infty$. Then any open connected subset $U$ of $V$ which is $T$-invariant and contains the origin, is such that $\text{Pol}(U)$ is dense in $\mathcal{O}_V(U)$.

**Proof.** We may assume that $V = \mathbb{C}^{m|n}$ with $T$-action

$$t, (z_1, \ldots, \xi_{m+n}) \mapsto (f_1(t)z_1, \ldots, f_{m+n}(t)\xi_{m+n})$$

where the $f_j$ are characters of $T$. Let $U$ be an open connected subset of $\mathbb{C}^{m|n}$ containing the origin and stable under $T$. The action of $T$ induces an action on $\mathcal{O}_V(U)$. It is enough to prove that the closure of $\text{Pol}(\mathbb{C}^{m|n})$ contains $\mathcal{O}_V(U)\cap$ the smooth vectors in $\mathcal{O}_V(U)$ with respect to the $T$ action, since we know such space is dense in $\mathcal{O}_V(U)$. Since the Fourier series of any $g$ in $\mathcal{O}_V(U)$ converges to $g$ (see Prop. 3.11 (5) and (6)), it is enough to show that any eigenfunction of $T$ in $\mathcal{O}_V(U)$ is a polynomial. Suppose $g \neq 0$ is in $\mathcal{O}_V(U)$ such that $t^{-1} \cdot g = f(t)g$ for all $t \in T$ and $u \in U$, $f$ being a character of $T$. Since $0 \in U$ we can expand $g$ as a power series $g(u) = \sum c_r u^r$ in a polydisk, where $u$ comprehends even and odd coordinates and we are using the multiindex notation. Notice that the action of $T$ preserves the polidisks, and we have

$$(t^{-1}g)(u) = g(tu) = \sum r c_r (tu)^r = \sum r c_r f^r(t)u^r = f(t)g = \sum r c_r f(t)u^r$$

Then $c_r f^r = c_r f$ whenever $c_r \neq 0$, because $t^{-1} \cdot g = f(t)g$. So only the $r$ with $f = f^r$ appear in the expansion of $g$. We claim that there are only finitely many such $r$; once this claim is proven we are done, because $g$ is a linear combination of the monomials $u^r$ with $f^r = f$, hence $g$ is a polynomial. To prove the claim, note that all such $u^r$ are eigenfunctions for $T$ for the eigencharacter $f$, and by assumption, there are only finitely many of these. 

We want to apply the previous lemma in a case that is of interest to us.

Define now $\Gamma_1 = G_r B^+/B^+$ and $\Gamma_2 = (\Gamma \cap G_r B^+)^0/B^+$ (the suffix “0” denotes the connected component of the identity). These are open sets in $G/B^+$ which are invariant under the $A_r$ action. Let us denote with $\mathcal{P}^r(\Gamma_2)$, the set $(\mathcal{P}|_{\Gamma_2^r})^r$ where $\Gamma_2^r \cong \Gamma_2$ in the isomorphism of analytic supermanifolds $N^- \cong \Gamma/B^+$.

**Corollary 4.13.** Let the notation be as above.
(1) \( \overline{\mathcal{P}} = \mathcal{O}(N^-) \), where the nilpotent supergroup \( N^- \) is interpreted as a vector superspace via the identification \( n^- \cong N^- \) via the exponential morphism.

(2) \( \overline{\mathcal{P}} = L^\chi(\Gamma) \), \( \Gamma = N^-AN^+ \) the big cell in \( G \).

(3) \( \overline{\mathcal{P}}(\Gamma_2) = L^\chi(\Gamma_2) \).

**Proof.** (1) We apply Lemma 4.12. The torus \( A_r \) acts on \( N^- \) through the action \( c \) given by (8). The condition \( \dim \text{Pol}(\tau) < \infty \) is checked with a calculation completely similar to that of Corollary 4.11. (2) is a consequence of the isomorphism (7). (3) follows again from Lemma 4.12.

Define now \( F = L^\chi(\Gamma) \), \( F^1 = L^\chi(\Gamma_1) \), \( F^2 = L^\chi(\Gamma_2) \). Notice that on \( F \) and \( F^2 \) we do not have any \( G \) or \( G_r \) action, only \( F^1 \) is a \( G_r \) module in a natural way.

**Corollary 4.14.** Let the notation be as above.

1. The restriction morphism \( F^1 \to F^2 \) is a continuous injection.
2. Under the restriction, \( F^1(\tau) \subset F^2(\tau) \) for characters \( \tau \) of \( A_r \).
3. \( F^2(\tau) = F(\tau)|_{\Gamma_2} \).

**Proof.** (1) and (2) are clear, (1) because \( \Gamma_2 \) is open in \( \Gamma_1 \) and of the analytic continuation principle, which holds also in the supersetting, while (2) is a simple check. Now we go to (3). The space of polynomials \( \text{Pol}(\Gamma) \) on \( \Gamma \) is dense in \( F \) and by Corollary 4.11 we have \( F^0 = \text{Pol}(\Gamma) \). \( \text{Pol}(\Gamma_2) = \text{Pol}(\Gamma)|_{\Gamma_2} \) is dense in \( F^2 \) by the previous corollary. Since \( \text{Pol}(\Gamma_2) \) is dense in \( F^2 \), we have that the restriction of \( F(\tau) \) to \( \Gamma_2 \) is dense in \( F^2(\tau) \) and since \( F(\tau) \) is finite dimensional we have \( F(\tau)|_{\Gamma_2} = F^2(\tau) \).

4.4. The action of \( \mathcal{U}(\mathfrak{g}) \) on \( L^\chi(\Gamma) \). We start by defining the natural action of \( \mathcal{U}(\mathfrak{g}) \) on the holomorphic functions on any neighbourhood \( W \) of the identity of the supergroup \( G \).

**Definition 4.15.** Let \( W \subset G \) be an open neighbourhood of the identity \( 1_G \) in \( G \). There are two well defined actions of \( \mathfrak{g} \), hence of \( \mathcal{U}(\mathfrak{g}) \), on \( \mathcal{O}(W) \) that read as follows:

\[
\ell(X)f = (-X \otimes 1)\mu^*(f), \quad X \in \mathfrak{g} \\
\partial(X)f = (1 \otimes X)\mu^*(f)
\]

**Proposition 4.16.** Let \( U \) be open in \( \widetilde{G/B^+} \). Then \( \ell \) and \( \partial \) are well defined actions on \( \mathcal{O}(U) \) and they commute with each other.

**Proof.** Immediate.

The natural action of \( \mathcal{U}(\mathfrak{g}) \) on \( L^\chi(N^-B^+) \) is algebraic, hence it preserves \( \mathcal{P}^- \). The proof is analogous to the classical one and we leave the details to the reader.

**Proposition 4.17.** The action \( \ell \) of \( \mathcal{U}(\mathfrak{g}) \) on \( L^\chi(U) \), \( p^{-1}(U) \subset \Gamma \) leaves \( \mathcal{P}^- \) invariant.

We now want to establish a fundamental pairing between a certain Verma module and the space of polynomials inside \( L^\chi(\Gamma) \). We start by recalling the notion of pairing between \( \mathfrak{g} \)-modules.

**Definition 4.18.** Let \( M_1, M_2 \) be two modules for \( \mathfrak{g} \). By a \( \mathfrak{g} \)-pairing between them we mean a bilinear form \( \langle \cdot, \cdot \rangle \) on \( M_1 \times M_2 \) with the property that:

\[
\langle Xm_1, m_2 \rangle = \langle m_1, -(1)^{|m_1||X|}Xm_2 \rangle, \quad m_i \in M_i, \ X \in \mathfrak{g}.
\]
Since the $M_i$ are modules for $\mathcal{U}(\mathfrak{g})$ this implies that
\[
\langle X_1 \ldots X_r m_1, m_2 \rangle = \langle m_1, (-1)^{r+|m_1|(|X_1|+\ldots+|X_r|)+l_{\text{odd}}(w)} X_r \ldots X_1 m_2 \rangle
\]
where $l_{\text{odd}}(w)$ is the (minimum) number of odd transpositions appearing in the permutation $w : (1, \ldots, r) \mapsto (r, \ldots, 1)$. The map $X \mapsto -X$ of $\mathfrak{g}$ is an involutive anti-automorphism of $\mathfrak{g}$. It extends uniquely to an involutive anti-automorphism $u \mapsto u^T$ of $\mathcal{U}(\mathfrak{g})$. The $\mathfrak{g}$-pairing requirement is equivalent to
\[
\langle um_1, m_2 \rangle = \langle m_1, (-1)^{|u||m_1|} u^T m_2 \rangle, \quad m_i \in M_i, \ u \in \mathcal{U}(\mathfrak{g}).
\]
We refer to this as a $\mathcal{U}(\mathfrak{g})$-pairing also. The pairing is said to be non-singular if $\langle m_1, m_2 \rangle = 0$ for all $m_2$ (resp. for all $m_1$) implies that $m_1 = 0$ (resp. $m_2 = 0$).

**Proposition 4.19.** Let $u$ and $v$ in $\mathcal{U}(\mathfrak{g})$, $f \in \mathcal{P}^\sim$.

1. $\partial(u^T f)(1_G) = (\ell(u) f)(1_G)$
2. $\partial(u)\ell(v)(f)(1_G) = (-1)^{|u||v|} \ell(v) \partial(u)(f)(1_G)$

where $1_G$ denotes the identity element in $G$.

**Proof.** (1). It is enough to prove for $u = X$ and $v = Y$ both in $\mathfrak{g}$. We can rewrite our equality as:
\[
(\epsilon \otimes 1)(1 \otimes -X) \mu^*(f) = (1 \otimes \epsilon)(-X \otimes 1) \mu^*(f)
\]
where $\epsilon$ is the counit morphism: $\epsilon(f) = f(1_G) \ \forall f \in \mathcal{P}^\sim$. We have:
\[
(\epsilon \otimes 1)(1 \otimes X) \mu^*(f) = (1 \otimes X)(\epsilon \otimes 1) \mu^*(f) = X(f)
\]
since $(\epsilon \otimes 1) \mu^*(f) = f$. On the other hand:
\[
(1 \otimes \epsilon)(X \otimes 1) \mu^*(f) = (X \otimes 1)(1 \otimes \epsilon) \mu^*(f) = X(f).
\]

(2). Again it is enough to prove for $u = X$ and $v = Y$ both in $\mathfrak{g}$.
\[
\partial(X)\ell(Y)(f)(1_G) = (\epsilon \otimes 1)(1 \otimes X) \mu^*(-Y \otimes 1) \mu^*(f) =
\]
\[
= (-1)^{|X||Y|}(-Y \otimes X) \mu^*(f)(1_G).
\]
because $(\epsilon \otimes 1) \mu^*(f) = f$. Similarly
\[
\ell(Y)\partial(X)(f)(1_G) = (1 \otimes \epsilon)(-Y \otimes 1) \mu^*(1 \otimes X) \mu^*(f) =
\]
\[
= (-Y \otimes X) \mu^*(f)(1_G).
\]

**Lemma 4.20.** Let $\lambda \in \mathfrak{h}^*$, and let
\[
\mathcal{M}_\lambda := \sum_{\alpha > 0} \mathcal{U}(\mathfrak{g})\mathfrak{g}_\alpha + \sum_{H \in \mathfrak{h}} \mathcal{U}(\mathfrak{g})(H + \lambda(H))
\]
then $\mathcal{M}_\lambda$ is a left ideal and
\[
\mathcal{U}(\mathfrak{g}) = \mathcal{M}_\lambda \oplus \mathcal{U}(\mathfrak{n}^-)
\]

**Proof.** For the ordinary setting this is Lemma 4.6.6 in [16]. As for the supersetting it is the same.
Theorem 4.21. There is a non-singular $\mathcal{U}(\mathfrak{g})$-pairing between $\mathcal{P}^\sim$ and the Verma module $V_\lambda$. Moreover every non-zero submodule of $\mathcal{P}^\sim$ contains the element $1^\sim$ corresponding to the constant function $1 \in \mathcal{P}$. In particular, the submodule $\mathcal{I}^\sim$ of $\mathcal{P}^\sim$ generated by $1^\sim$ is irreducible and is the unique irreducible submodule of $\mathcal{P}^\sim$. Finally, $\mathcal{I}^\sim$ is the unique irreducible module of lowest weight $-\lambda$.

Proof. The proof is the same as for the ordinary setting, let us sketch it. We first define:

$$<,>: \mathcal{P}^\sim \times \mathcal{U}(\mathfrak{g}) \rightarrow \mathbb{C}, \quad <f, u> := (1)^{|u||f|}(\partial(u)f)(1_G)$$

In order for $<,>$ to be a $\mathfrak{g}$-pairing, we need to verify:

$$<\ell(c)f, u> = <f, (1)^{|f||c|}c^T u>, \quad c, u \in \mathcal{U}(\mathfrak{g}), f \in \mathcal{P}^\sim$$

where $(\cdot)^T$ denotes the antiautomorphism of $\mathcal{U}(\mathfrak{g})$ induced by $X \mapsto -X$ with $X \in \mathfrak{g}$. We have by the previous proposition:

$$<\ell(c)f, u> = (1)^{|u||c|+|f|}(\partial(u)\ell(c)f)(1_G) = (1)^{|u||f|}(\ell(c)\partial(u)f)(1_G) =$$

$$= (1)^{|u||f|}(\partial(c^T)\partial(u)f)(1_G) =$$

$$= (1)^{|u||f|}(\partial(c^Tu)f)(1_G) = <f, (1)^{|f||c|}c^T u>$$

By Lemma 4.20, in order to prove that the bilinear map $<,>$ descends to a $\mathfrak{g}$-pairing between $\mathcal{P}^\sim$ and $V_\lambda$ we need to prove that

$$u \in \mathcal{M}_\lambda \iff (\partial(u)f)(1_G) = 0$$

For sufficiency, we notice that $<f, X_\alpha> = \partial(X_\alpha)(f)(1_G) = D_{X_\alpha}^L(f) = \lambda(-X_\alpha) = 0$ by (4.1). Again by (4.1), we have that $<f, H> = D_H^L(f) = -\lambda(H)f(1_G)$. For necessity, suppose that $(\partial(u)f)(1_G) = 0$ for each $f \in \mathcal{P}^\sim$. By Lemma 4.20 it is enough to notice that for each $X \in \mathcal{U}(\mathfrak{n}^\sim)$ there exists a polynomial $p \in \mathcal{P}$ such that $D_{X^\sim}^L(1_G) \neq 0$. So we have obtained a nonsingular pairing

$$\mathcal{P}_\lambda^\sim \subset V_\lambda^\sim$$

They are both weight spaces, for each weight the corresponding weight spaces having the same dimension (See Corollary 4.11), hence they are isomorphic.

More explicitly, the functions $(t^r)^\sim = (t_{r_1}^{r_1} \ldots t_{r_n}^{r_n})^\sim$, corresponding to the coordinate polynomials $t^r$ on $N^\sim$, are weight vectors for the action of $\mathfrak{h}$ for the weight $r - \lambda$. Hence $\mathcal{P}^\sim$ is a weight module with the multiplicities defined in Sec. 4.3. We shall prove that every non-zero $\ell$-invariant subspace $W$ of $\mathcal{P}^\sim$ contains the vector $1^\sim$ defined by the constant function 1 on $N^\sim$. Now $W$ is a sum of weight spaces and if it does not contain $1^\sim$, then $W$ is contained in the sum of all weight spaces corresponding to the weights $-\lambda + r$ where $r = (r_i)$ with some $r_i > 0$. Now $<\ell(H)m_1, m_2> = -<m_1, \partial(H)m_2>$, for all $H \in \mathfrak{h}$, $m_1 \in \mathcal{P}^\sim$, $m_2 \in V_\lambda$. This shows that the weight space of $\mathcal{P}^\sim$ for the weight $\theta$ is orthogonal to the weight space of $V_\lambda$ for the weight $\phi$ unless $\theta = -\phi$. Let $v$ be a non-zero vector of highest weight $\lambda$ in $V_\lambda$. Since $W$ is contained in the span of weights other than $-\lambda$, we have $<W, v> = 0$. Hence, for all $g \in \mathcal{U}(\mathfrak{g})$, $w \in W$ we have $<\ell(g)w, v> = 0$. So $<w, g^Tv> = 0$ for all $g \in \mathcal{U}(\mathfrak{g})$. But $v$ is cyclic for $V_\lambda$ and so we have $<w, V_\lambda >= 0$ for all $w \in W$. This means that $W = 0$, contradicting the hypothesis that $W \neq 0$. Thus every non-zero submodule of $\mathcal{P}^\sim$ contains the submodule $\mathcal{I}^\sim$ generated by $1^\sim$. This submodule is then the unique irreducible submodule of $\mathcal{P}^\sim$. The weights of $\mathcal{I}^\sim$ are of the form $-\lambda + d$ where $d$ is a positive integral linear
4.5. **Harish-Chandra decomposition.** From now on we fix a positive admissible system $P$ for $\mathfrak{g}$ (see Sec. 2.2).

Let $P^+$ be the analytic supergroup corresponding to the subsuperalgebra $\mathfrak{p}^+ = \sum_{\beta \in P} \mathfrak{g}_\beta$. Similarly define $P^-$. Let $K$ be the (ordinary) analytic subgroup of $G$ corresponding to the Lie superalgebra $\mathfrak{k} = \mathfrak{k}_0$.

**Proposition 4.22.** The morphism $\phi : P^- \times K \times P^+ \rightarrow G$, defined as $(p^-, k, p^+) \mapsto p^- kp^+$ in the functor of points notation, is a complex analytic isomorphism of $P^- \times K \times P^+$ onto an open set $\Omega \subset G$.

**Proposition 4.23.**

1. $G_{rK} \mathbb{R}(\mathfrak{p}^+)^\mathbb{R}$ is an open subsupermanifold in $(P^- K \mathfrak{p}^+)^\mathbb{R}$.
2. $G_{rK} \mathbb{R}(\mathfrak{p}^+)^\mathbb{R}$ is a complex open subsupermanifold in $P^- K \mathfrak{p}^+$.
3. $\tilde{G}_r \cap \tilde{K} \mathfrak{p}^+ = \tilde{K}$.

**Proof.** For the first statement, observe that $\mathfrak{g}_r \oplus \mathfrak{t} \oplus \mathfrak{p}^+ = \mathfrak{g}$, by Prop. 4.1, because $\mathfrak{t} \oplus \mathfrak{p}^+ \supset \mathfrak{b}$. Hence by Lemma 3.6 we have that $G_{rK} \mathfrak{p}^+$ is open in $G$ and since $G_{rK} \tilde{\mathfrak{p}}^+ \subset \tilde{P}^- \tilde{K} \mathfrak{p}^+$ (see [28] pg. 389), we have $G_{rK} \mathfrak{p}^+$ is open in $P^- K \mathfrak{p}^+$. The second statement is topological, so it is true because of the ordinary theory.

We now turn to the construction of the complex structure of $G_{rK}$.

**Proposition 4.24.** We have $G_{rK} \cong (G_{rK} \mathfrak{p}^+/K \mathfrak{p}^+)^\mathbb{R}$. Hence and $G_{rK}$ acquires a natural $\tilde{G}_r$ invariant complex structure.

**Proof.** This is an immediate consequence of Lemma 3.6 (2) and (3), together with Prop. 4.23.

4.6. **Harish-Chandra representations and their geometric realization.** In this section we give a global realization of the Harish-Chandra infinitesimal representations studied in Sec. 2.3.

**Definition 4.25.** Let the complex vector superspace $V$ be a $\mathfrak{g}$-module via the representation $\pi$. We say that $V$ is a $(\mathfrak{g}_r, K_r)$-module if there exists a representation $\pi_{K_r}$ of $K_r$ such that

1. $\pi(\text{Ad}(k)X) = \pi_{K_r}(k)\pi(X)\pi_{K_r}(k)^{-1}$
2. $V = \sum_{\tau} V(\tau)$ where the sum is algebraic and direct and $V(\tau)$ is the span of all the linear finite dimensional subspaces corresponding to the irreducible representation associated with the $K_r$-character $\tau$.

We say that $V$ is a $(\mathfrak{g}_r, \mathfrak{t}_r)$-module if

$$V = \sum_{\theta \in \Theta} V(\theta)$$

where the sum is algebraic and direct, $\Theta$ denotes the set of equivalence classes of the finite dimensional irreducible representations of $\mathfrak{t}$ and $V(\theta)$ is the sum of all representation occurring in $V$ lying in one of such classes $\theta \in \Theta$. 

---
We say that the \((\mathfrak{g}_r, K_r)\)-module \(V\) is a Harish-Chandra module (or HC-module for short) if each \(V(\tau)\) is finite dimensional and \(V\) is finitely generated as \(\mathcal{U}(\mathfrak{g})\) module. Similarly we can define also the notion of Harish-Chandra modules for \((\mathfrak{g}_r, \mathfrak{t}_r)\)-modules.

We say that a vector is \(K_r\)-finite if it lies in a finite dimensional \(K_r\) stable subspace.

We now want to study the action of \(G_r\) on a superspace of sections of the line bundle \(L^X\) over \(G/B^+\). Since \(\tilde{G}, B^+\) is open in \(\tilde{G}\) (see Lemma 3.7), we can consider \(L^X(G_rB^+)\) and since \(G_r\) acts on the left on \(G_rB^+\) we have a well defined action of \(G_r\) on the Frechét superspace \(L^X(G_rB^+/B^+)\):

\[
\begin{align*}
(g \cdot f) &= l_{g^{-1}}^* f \quad g \in \tilde{G}_r \\
X.f &= D^R_X f \quad X \in \mathfrak{g}
\end{align*}
\]

Next lemma is a simple generalization of Theorem 11, pg 312 in [48] and holds in a general setting.

**Lemma 4.26.** Let the notation be as above. Let \(F\) be a Frechét representation of \(G_r\) on which \(G_r\) acts via \(\pi = (\pi_0, \rho)\). If \(v\) is a weakly analytic vector for \(\tilde{G}_r\), then

\[
\overline{\mathcal{U}(\mathfrak{g})} v \subseteq F
\]

is the smallest closed \(G_r\)-invariant subspace of \(F\) containing \(v\).

**Proof.** For each \(X \in \mathcal{U}(\mathfrak{g})\) and \(\lambda \in F^* \) (the topological dual of \(F\)), define the function \(f_{X,\lambda} : \tilde{G}_r \to \mathbb{C} : \)

\[
f_{X,\lambda}(g) = \lambda(\pi_0(g)\rho(X)v)
\]

Let \(\lambda\) be such that \(\lambda = 0\) on \(\overline{\mathcal{U}(\mathfrak{g})} v\). It is easily checked that the infinitesimal action of \(\mathcal{U}(\mathfrak{g}_0,\mathfrak{r})\) preserves the analytic vectors hence we obtain

\[
Z f_{X,\lambda}(1_g) = 0 \quad \text{for each } Z \in \mathcal{U}(\mathfrak{g}_0)
\]

Since \(\tilde{G}_r\) is connected, we conclude that \(f_{X,\lambda} = 0\) on \(\tilde{G}_r\). Hence by the Hahn-Banach theorem we conclude that \(\text{span}\{\pi_0(G)\rho(X)v\}\) is contained in \(\overline{\mathcal{U}(\mathfrak{g})} v\). Since this is true for all \(X \in \mathcal{U}(\mathfrak{g})\) we conclude that \(\overline{\mathcal{U}(\mathfrak{g})} v\) is \(G_r\) invariant. Since

\[
\rho(Y)\pi_0(g)\rho(X)v = \pi_0(g)\rho((g^{-1}Y)X)v
\]

it is also clear that it is the smallest \(G_r\)-invariant subspace of \(F\) containing \(v\). \(\blacksquare\)

Let us introduce the notation:

\[
(4.2) \quad L^X(U) := \{\tilde{f} | f \in L^X(U)\}
\]

which is meaningful because \(L^X\) is a subsheaf of the structural sheaf.

**Theorem 4.27.** Let \(S = G_rB^+/B^+\) and assume \(\tilde{F}^1 := \tilde{L}^X(S) \neq 0\). Then:

\begin{enumerate}
  
  \item \(F^1\) contains an element \(\psi\) which is an analytic continuation of \(1^\sim\);
  \item \(F^{11} := \ell(\mathcal{U}(\mathfrak{g}))\psi \subset L^X(S)\) is a Fréchet \(G_r\)-module, \(K_r\)-finite and with \(K_r\)-finite part \(\ell(\mathcal{U}(\mathfrak{g}))\psi = \mathcal{P}^\sim\).
  \item the \(K_r\)-finite part \(\mathcal{P}^\sim\) is isomorphic to \(\pi_{-\lambda}\) the irreducible representation with lowest weight \(-\lambda\). In particular \(\lambda(H_a) \in \mathbb{Z}_{\geq 0}\) for all compact positive roots \(\alpha\).
\end{enumerate}
Proof. We first establish the $K_r$-finiteness of $F^1$. From (2) of Corollary 4.13 it follows that the subspace $F^1(\tau)$ injects (through the restriction morphism) in $F^2(\tau)$, where $F^2$ denotes $L^\lambda(\Gamma_2)$ (we recall that $\Gamma_2 = (G, B^+ \cap \Gamma)^0 / B^+$). From (3) of Corollary 4.13, we know that $\dim F^2(\tau) = \dim F(\tau)$. By (3) of Corollary 4.13 and (2) of Corollary 4.11, we finally obtain $\dim F(\tau) < +\infty$. Hence $F^1$ is $A_r$-finite. By Corollary 3.13 the $A_r$-finiteness implies in our case the $K_r$-finiteness. Hence $F^1$ is $K_r$-finite.

We now go to the proof of (1). Assume that the $K_r$-finite part $(F^1)^0 = \sum F^1(\tau)$ does not include the weight $-\lambda$, in other words we assume there is no analytic continuation of $1^\sim$ to $S$. By Corollary 4.13 and Corollary 4.14, $(F^1)^0$ is isomorphic to a subset of the set of polynomials in the $t_\alpha$ (see Sec. 4.2 for the notation). Since $1^\sim \in F^2(-\lambda) \supseteq F^1(-\lambda)$ we have that all the elements $f$ in $(F^1)^0$ are zero when evaluated at $1_G$. Hence, by the density of $(F^1)^0$ in $F^1$, all the elements in $F^1$ vanish at $1_G$. Using the $G_r$ action it follows that $\hat{f} = 0$ for all $f \in F^1$.

As for (2), $F^{11} := \overline{\ell(U(g))\psi}$ is a Fréchet superspace, since it is a closed subspace of a Fréchet superspace. The fact that $F^{11}$ is a $G_r$-module follows from Lemma 4.26. Hence $F^{11}$ is a $G_r$ submodule of $F^1$, and it is $K_r$-finite since it is a submodule of the $K_r$ finite module $F^1$. $\mathcal{J} = \ell(U(g))\psi$ is clearly a highest weight $U(g)$ module. Since $F^{11}$ is the closure of the $K_r$-finite subspace $\mathcal{J}$ subspace, its $K_r$-finite part is precisely $\mathcal{J}$.

(3). We know that $\mathcal{J} \subset (F^1)^0 \hookrightarrow (F^2)^0 \simeq F^0$. Clearly $\mathcal{J} \hookrightarrow \mathcal{I}^\sim := U(g)1^\sim \subset F^0$, but since by (4.21) $\mathcal{I}^\sim$ is irreducible, we have $\mathcal{J} = \mathcal{I}^\sim$. $\mathcal{J}$ is the irreducible lowest weight module of lowest weight $-\lambda$ or equivalently $\mathcal{J}$ is the irreducible highest weight module of highest weight $-\lambda$ with respect to the positive system $-\mathcal{P}$. The $K_r$-finiteness of $\mathcal{J}$ implies that $-\lambda(H_{-\alpha}) \geq 0$, hence our result.

Corollary 4.28. Let the notation be as above. Then $\mathcal{J} = U(g)\psi \subset (F^1)^0$ is the irreducible Harish-Chandra module with highest weight $-\lambda$ with respect to the positive system $-\mathcal{P}$.

Proof. This is an immediate consequence of Proposition 2.8

Definition 4.29. We say that a dominant integral weight $\lambda$ is $K$-integrable if the $\mathfrak{t}$ irreducible representation associated with $\lambda$ can be lifted to $K$.

Definition 4.30. An holomorphic character $\chi_\lambda$ of $A$ is $K$-integrable if $\lambda$ is dominant integral for the positive compact roots and if the associated $\mathfrak{t}$ representation can be lifted to $K$. In this case, we also say that $\lambda$ is $K$-integrable.

As in the classical case we have the following Lemma.

Lemma 4.31. If $\lambda$ is $K$-integrable then the associated representation of $K$ is finite-dimensional and holomorphic.

Proof. This fact is entirely classical and it is proved in [27].

Theorem 4.32. Let the notation be as above. Assume the following:

- $\dim(c) \geq 1$.
- $\lambda \in \mathfrak{h}^*$ is integral and $\lambda(H_\alpha) \geq 0$ for all $\alpha$ compact positive root.
- $\lambda$ is $K$-integrable.
Then $L^\chi(G,B^+) \neq 0$ and $F^{11}$ is a $G_r$ representation whose $K_r$-finite part is the lowest weight representation $\pi_{-\lambda}$.

Proof. It is enough to show that $L^\chi(G,B^+) \neq 0$, since (2) is an immediate consequence of Theorem 4.27. Let $\sigma_\lambda$ be the finite dimensional irreducible representation of $K$ with highest weight $\lambda$ on the vector space $V$. Let $v_\lambda$ be the corresponding highest weight vector. We can define the coefficient of the representation $\sigma_\lambda$ corresponding to $v_\lambda$ that is the nonzero section $a_{11} : K \rightarrow \mathbb{C}$, $a_{11}(k) = (\sigma_\lambda(k)v_\lambda)_{v_{11}}$, that is the $v_\lambda$ component of $\sigma_\lambda(k)v_\lambda$ corresponding to the weight decomposition of $V$. Using Prop. 4.22, we can extend $a_{11}$ to a nonzero section in $\mathcal{O}(P^- KP^+)$. Since $G_r$ is embedded into $(P^- KP^+)^+$ and $a_{11}(1_G) = 1$ we obtain a non zero section of $G_r$, that is $a_{11} \in \mathcal{O}(G_r)$. It is immediate to verify:

$$r^*_ba_{11} = \chi_0^\lambda(b)^{-1}a_{11}, \quad b \in B^+, \quad D^b_Xa_{11} = -\lambda(X)a_{11}, \quad X \in b^+$$

so that $a_{11} \in L^\chi(S)$ as requested. □

4.7. The Siegel superspace. To illustrate the theory developed so far, we want to give an example, interesting by itself, where the various geometrical tools developed so far (admissible systems, symmetric superspaces,...) come into play.

Consider the closed complex analytic subsupergroup $P$ of the complex orthosymplectic supergroup $\text{Osp}(m|2n)$ defined, via its functor of points, as:

$$P(T) = \left\{ \begin{pmatrix} a & 0 & \alpha_2 \\ b_{11}a & b_{12} & \alpha_2 \\ 0 & 0 & (b_{11}'^t)^{-1} \end{pmatrix} \bigg\| \begin{pmatrix} a'ta = 1 \\ (b_{11}^{-1}b_{12}) - (b_{11}^{-1}b_{12})^t = \alpha_2'^t\alpha_2 \end{pmatrix} \right\}$$

where $a \in \text{GL}(m)(T)$, $b_{11} \in \text{GL}(n)(T)$, $b_{12} \in \text{M}(n)(T)$, $\alpha_2 \in \text{M}(m|0,0|n)(T)$, $T \in (\text{smflds})_{\mathbb{C}}$, (GL, M denoting respectively the general linear (super)group and the (super)matrices).

As for any closed analytic subsupergroup of an analytic Lie supergroup it is possible to construct the quotient $\text{Osp}(m|2n)/P$. This is a complex analytic supermanifold, that we call the super Lagrangian and denote it by $\mathcal{L}$. Notice that, by the very definition, the reduced manifold of $\mathcal{L}$ is $\tilde{\mathcal{L}}$, the ordinary Lagrangian manifold in $\text{Sp}(2n, \mathbb{C})$, and we have a natural transitive action of $\text{Osp}(m|2n)$ on the supermanifold $\mathcal{L}$. We also define $\mathcal{L}_t$ as the open subsupersmanifold of $\mathcal{L}$ corresponding to the open subset $\tilde{\mathcal{L}}_t$ of $\tilde{\mathcal{L}}$

$$\tilde{\mathcal{L}}_t = \left\{ \begin{pmatrix} Z_1 \\ Z_2 \end{pmatrix} \bigg| Z_1^tZ_2 \text{ symmetric, } \text{det}(Z_2) \neq 0 \right\} / \text{GL}(n)(\mathbb{C})$$

$$\cong \left\{ \begin{pmatrix} Z \\ 1 \end{pmatrix} \bigg| Z \text{ symmetric} \right\} = \{ X + iY \mid X, Y \in \text{M}(2n,n)(\mathbb{R}), \text{ symmetric} \}.$$

We now want to characterize the functor of points of $\mathcal{L}_t$. We start observing that we can always choose uniquely a representative of the class

$$a \begin{pmatrix} \alpha_1 & \alpha_2 \\ \beta_1 & b_{11} & b_{12} \\ \beta_2 & b_{21} & b_{22} \end{pmatrix} P(T) \in \mathcal{L}_t,$$

in the form

$$\begin{pmatrix} 1 & \zeta & 0 \\ \zeta^t & z & -1 \\ 0 & 1 & 0 \end{pmatrix}$$
This is equivalent, to to find $z, \zeta, u, v, w, \xi$ depending on $\alpha_i, \beta_i$ and $a, b_{ij}$ in the following equation:

$$
\begin{pmatrix}
1 & 0 & -\zeta \\
0 & 0 & 1 \\
\zeta^t & -1 & z - \zeta^t \zeta
\end{pmatrix}
\begin{pmatrix}
a & \alpha_1 & \alpha_2 \\
\beta_1 & b_{11} & b_{12} \\
\beta_2 & b_{21} & b_{22}
\end{pmatrix}
= 
\begin{pmatrix}
u & 0 & \xi \\
v \xi^t u & v & w \\
0 & 0 & (v^t)^{-1}
\end{pmatrix}
$$

Notice that there is no loss of generality in assuming $b_{21} = 1$. The check the solutions are unique and compatible with the conditions defining $\text{Osp}(m|2n)$ is a direct calculation. The values obtained are:

$$u = a - \alpha_1 \beta_2, \quad \xi = \alpha_2 - \alpha_1 b_{22}, \quad v = 1, \quad w = b_{22}, \quad z = b_{11}, \quad \zeta = \alpha_1$$

**Proposition 4.33.** The $T$-points of the supermanifold $\mathcal{L}_f$ are identified with the matrices in $\text{Osp}(m|2n)(T)$ of the form:

$$\mathcal{L}_f(T) \simeq \left\{ \begin{pmatrix} 1 & \zeta & 0 \\
\zeta^t & z & -1 \\
0 & 1 & 0 \end{pmatrix} \mid \zeta^t \zeta + z^t - z = 0 \right\}.$$ 

Hence $\mathcal{L}_f \cong \mathbb{C}^{n^2+n|mn}$.

**Proof.** Let us choose a suitable open cover $\{T_i\}_{i \in T}$ of $T$, so that

$$\mathcal{L}(T_i) = \left( \text{Osp}(m|2n)/P(T_i) = \text{Osp}(m|2n)(T_i)/P(T_i) \right).$$

We can then write

$$\mathcal{L}_f(T_i) = \left\{ \begin{pmatrix} a & \alpha_1 & \alpha_2 \\
\beta_1 & b_{11} & b_{12} \\
\beta_2 & b_{21} & b_{22} \end{pmatrix} P(T_i) \mid \beta_{21} \text{ invertible} \right\}.$$

By (4.3), we can write:

$$\begin{pmatrix} a & \alpha_1 & \alpha_2 \\
\beta_1 & b_{11} & b_{12} \\
\beta_2 & b_{21} & b_{22} \end{pmatrix} P(T_i) = 
\begin{pmatrix} 1 & \zeta & 0 \\
\zeta^t & z & -1 \\
0 & 1 & 0 \end{pmatrix} P(T_i), \quad \zeta^t \zeta + z^t - z = 0.$$

$\mathcal{L}_f$ is then defined by $n(n - 1)/2$ equations in $\mathbb{C}^{n^2|mn}$:

$$\sum_k \zeta_{ki} \zeta_{kj} + z_{ji} - z_{ij} = 0, \quad 1 \leq i < j \leq n$$

**Definition 4.34.** We define Siegel superspace the open supermanifold of $\mathcal{L}_f$ corresponding to the complex open subset:

$$\tilde{S} = \{ Z \mid Z = X + iY, X, Y \in \text{M}(2n, n) \text{ symmetric, } Y > 0 \} \subset \tilde{\mathcal{L}}_f$$

By the Chart Theorem (see Ch. 4 in [S]) we have that a $T$-point of the Siegel superspace $\tilde{S}$ corresponds to a choice of two matrices $\zeta$ and $z$ with entries in $\mathcal{O}(T)$ such that their values at all topological points of $\tilde{T}$ land in $\tilde{S}$. In other words, $\mathcal{S}(T)$ consists of the following elements in $\mathcal{L}_f(T)$:

$$\mathcal{S}(T) = \left\{ \begin{pmatrix} 1 & \zeta & 0 \\
\zeta^t & z & -1 \\
0 & 1 & 0 \end{pmatrix} \mid \zeta^t \zeta + z^t - z = 0 \\
z = x + iy, \tilde{y}(t) > 0, \forall t \in \tilde{T} \right\} \subset \mathcal{L}_f(T).$$
We now want to realize the Siegel superspace as a real homogeneous supermanifold (for our notation see [10]).

Consider the natural action of the real orthosymplectic supergroup \( \text{Osp}(m|2n, \mathbb{R}) \) on the quotient \( \text{Osp}(m|2n)/P \) and restrict it to \( \mathcal{S} \):

\[
\text{Osp}(m|2n, \mathbb{R})(T) \times \mathcal{S}(T) \longrightarrow \mathcal{S}(T)
\]

\[
\begin{pmatrix}
 a & \alpha_1 & \alpha_2 \\
 \beta_1 & b_{11} & b_{12} \\
 \beta_2 & b_{21} & b_{22}
\end{pmatrix},
\begin{pmatrix}
 1 & \zeta & 0 \\
 -\zeta^t & z & -1 \\
 0 & 1 & 0
\end{pmatrix}
\longrightarrow
\begin{pmatrix}
 1 & \frac{a\zeta + \alpha_1 \zeta + \alpha_2}{b_{21}^2 + b_{21}b_{22} + b_{22}^2} & 0 \\
 \frac{a\zeta + \alpha_1 \zeta + \alpha_2}{b_{21}^2 + b_{21}b_{22} + b_{22}^2}^t & \frac{\beta_{11} + b_{11}b_{12} + b_{12}^2}{b_{21}^2 + b_{21}b_{22} + b_{22}^2} & -1 \\
 0 & 1 & 0
\end{pmatrix}
\]

**Theorem 4.35.** \( \text{Osp}(m|2n, \mathbb{R}) \) acts transitively on the Siegel superspace and the stabilizer of the topological point \((i, 0) \in \tilde{\mathcal{S}} \) is the subgroup:

\[
K_r(T) = \text{Stab}(iI, 0)(T) = \left\{ \begin{pmatrix}
 a & 0 & 0 \\
 0 & b_{11} & b_{12} \\
 0 & -b_{12} & b_{11}
\end{pmatrix} \in \text{Osp}(m|2n, \mathbb{R})(T) \right\}, \quad T \in (\text{smflds})_{\mathbb{R}}
\]

which is compact and coincides with its reduced group: \( (K_r)_{\text{red}} = K_r \) and it is equal to \( \text{O}(m) \times \text{U}(n) \). So we have the isomorphism as real supermanifolds:

\[
\mathcal{S} \cong \text{Osp}(m|2n, \mathbb{R})/K_r.
\]

**Proof.** The action of \( \text{Osp}(m|2n, \mathbb{R}) \) on \( \tilde{\mathcal{S}} \) is transitive. Consider the supermanifold morphism \( a_p : \text{Osp}(m|2n, \mathbb{R}) \longrightarrow \mathcal{S}, a_p(g) = g \cdot (0, iI) \). The differential \( (da_p)_I \) at the identity is surjective, hence the result follows (see also Prop. 9.1.4 in [3]). \( \square \)

The form we have found for \( K_r \) is not suitable for Lie superalgebra calculations, so we need to transform \( \mathcal{S} \), so that also \( K_r \) transforms accordingly. We shall do this via the super Cayley transform.

Consider the following linear transformation:

\[
L = \begin{pmatrix}
 1 & 0 & 0 \\
 0 & i/\sqrt{2}i & i/\sqrt{2}i \\
 0 & -1/\sqrt{2}i & 1/\sqrt{2}i
\end{pmatrix} \in \text{Osp}(m|2n)
\]

where we write 1 in place of the identity matrix.

Define the open subsupermanifold \( \mathcal{D} = (\tilde{\mathcal{D}}, \mathcal{O}_{\mathcal{L}^f|\tilde{\mathcal{D}}}) \) of \( \mathcal{L}_f \) with topological space:

\[
\tilde{\mathcal{D}} = \left\{ \begin{pmatrix}
 0 \\
z \\
 1
\end{pmatrix} \mid z \in \text{M}(n, n)(\mathbb{C}) \text{ symmetric}, 1 - z\overline{z} > 0 \right\}
\]

**Proposition 4.36.** The linear transformation \( L \) induces a supermanifold diffeomorphism:

\[
\phi_T : \mathcal{D}(T) \longrightarrow \mathcal{S}(T)
\]

\[
\begin{pmatrix}
 \eta \\
z \\
 1
\end{pmatrix} \longmapsto
\begin{pmatrix}
 \sqrt{2}i\eta(1 - z)^{-1} \\
i(z + 1)(1 - z)^{-1} \\
 1
\end{pmatrix}
\]
Proof. Let us take a generic element in $L_t(T)$ and multiply it by $L$:

$$
\begin{pmatrix}
1 & 0 & 0 \\
0 & \frac{i}{\sqrt{2i}} & \frac{i}{\sqrt{2i}} \\
0 & -1/\sqrt{2i} & 1/\sqrt{2i}
\end{pmatrix}
\begin{pmatrix}
\eta' \\
z \\
1
\end{pmatrix}
= \begin{pmatrix}
\eta \\
\frac{i}{\sqrt{2i}}(z + 1) \\
\frac{i}{\sqrt{2i}}(1 - z)
\end{pmatrix}
\sim \begin{pmatrix}
\sqrt{2i} \eta(1 - z)^{-1} \\
i(z + 1)(1 - z)^{-1}
\end{pmatrix}
$$

The map $\phi$ can be extended on the lagrangian $L_t$ (except at the locus $z = 1$) and it is differentiable on $\tilde{L}_t \setminus \{z = 1\}$. Since $\tilde{\phi}$ is an homeomorphism when restricted to $\tilde{D}$ and the differential $d\phi$ is surjective, the result follows (see [8]).

We call the diffeomorphism $\phi$ the super Cayley transform. Define:

$$\text{Osp}_{D}(m|2n)(T) := L^{-1}\text{Osp}(m|2n,\mathbb{R})(T)L, \quad K_D(T) := L^{-1}K_r(T)L$$

Proposition 4.37. $\text{Osp}_{D}(m|2n)$ is a real form of the orthosymplectic supergroup and its functor of points is explicitly given by:

$$\text{Osp}_{D}(m|2n)(T) = \left\{ \begin{pmatrix}
a_0 & \alpha_1 & -\bar{\alpha}_1 \\
\bar{\beta}_1 & \bar{b}_{11} & \bar{b}_{12} \\
\bar{\beta}_2 & \bar{b}_{21} & \bar{b}_{22}
\end{pmatrix} \right\} \subset \text{Osp}(m|2n)_{\mathbb{R}}(T)$$

where $a_0 \in \text{O}(m)$, $T$ is a real supermanifold and, as usual, $\text{Osp}(m|2n)_{\mathbb{R}}$ is the complex orthosymplectic supergroup viewed as a real supergroup.

$K_D$ is a real form of the compact group $K_r$ and it is given by

$$K_D = \left\{ \begin{pmatrix}
a_0 & 0 & 0 \\
0 & b_{11} & 0 \\
0 & 0 & \bar{b}_{11}
\end{pmatrix} \mid b_{11}\bar{b}_{11} = 1, \ a_0 \in \text{O}(m) \right\}$$

Proof. The conjugation defining $\text{Osp}_{D}(m|2n)$ inside $\text{Osp}(m|2n)$ is:

$$\begin{pmatrix}
a & \alpha_1 & \alpha_2 \\
\beta_1 & \bar{b}_{11} & \bar{b}_{12} \\
\beta_2 & \bar{b}_{21} & \bar{b}_{22}
\end{pmatrix}
\mapsto
\begin{pmatrix}
\bar{a} & -\bar{\alpha}_2 & -\bar{\alpha}_1 \\
i\bar{\beta}_1 & \bar{b}_{22} & \bar{b}_{21} \\
i\bar{\beta}_2 & \bar{b}_{12} & \bar{b}_{11}
\end{pmatrix}$$

The statement about $K_D$ is entirely classical and known.

Proposition 4.38. $\text{Osp}_{D}(m|2n)$ acts transitively on $D$ and $K_D$ is the stabilizer of the topological point $(1,0)$. Hence

$$D \cong \text{Osp}_{D}(m|2n)/K_D.$$  

Proof. It the same as for Proposition 4.35.

We now compute the real Lie superalgebras of $\text{Osp}_{D}(m|2n)$ and $K_D$.

Proposition 4.39. We have that

$$\text{osp}_{D}(m|2n) = \left\{ \begin{pmatrix}
x & \xi & -i\xi \\
-iy_{11} & y_{11} & y_{12} \\
-iy_{12} & y_{11} & y_{11}
\end{pmatrix} \mid \begin{cases}
y_{12} \text{ symmetric}, \\
x = -x^t, \ y_{11} = -y_{11}^t
\end{cases} \right\}$$

$$\mathfrak{k}_D = \text{Lie}(K_D) = \left\{ \begin{pmatrix}
x & 0 & 0 \\
0 & y_{11} & 0 \\
0 & 0 & y_{11}
\end{pmatrix} \right\}$$
Proof. The conjugation defining \( \text{osp}_D(m|2n) \) is obtained as follows:

\( X \in \text{osp}_D(m|2n) \) if and only if \( X \in \text{osp}(m|2n) \) and \( F\overline{X} = XF \) where \( F = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & i \\ 0 & i & 0 \end{pmatrix} \). An easy calculation shows the result.

For the complex Lie superalgebra (see Sec. 2.2) \( \text{osp}(m|2n) \) we have the admissible system

\[
P = P_k \cup P_{n,0} \cup P_{n,1},
\]

where:

\[
P_{n,0} = \{ \epsilon_1 \pm \epsilon_j \mid 1 < j \leq m \} \cup \{ \epsilon_1 \} \cup \{ \delta_i + \delta_j \mid 1 \leq i, j \leq n \}
\]

\[
P_{n,1} = \{ \delta_i \pm \epsilon_j \mid 1 \leq i \leq n, 1 \leq j \leq m \} \cup \{ \delta_i \mid 1 \leq i \leq n \}
\]

\[
P_k = \{ \epsilon_i \pm \epsilon_j \mid 1 < i < j \leq m \} \cup \{ \epsilon_i \mid 1 < i \leq m \} \cup \{ \delta_i - \delta_j \mid 1 \leq i < j \leq n \}
\]

with

\[
\Pi = \{ \epsilon_1 - \epsilon_2, \ldots, \epsilon_{m-1} - \epsilon_m, \epsilon_1, \delta_1 - \delta_2, \ldots, \delta_{n-1} - \delta_n, \delta_n - \epsilon_1 \}
\]

the simple system with one simple non-compact even root \( \epsilon_1 - \epsilon_2 \) and one non-compact simple odd root: \( \delta_n - \epsilon_1 \).

**Proposition 4.40.** The complex Lie superalgebra \( \text{osp}(m|2n) \) is the vector space direct sum of three Lie subsuperalgebras:

\[
\text{osp}(m|2n) = \mathfrak{t} \oplus \mathfrak{p}^+ \oplus \mathfrak{p}^-,
\]

where \( \mathfrak{t} = \mathbb{C} \otimes \text{Lie}(K_D) \) and

\[
\mathfrak{p}^+ = \left\{ \begin{pmatrix} 0 & 0 & \xi \\ \xi^t & 0 & u \\ 0 & 0 & 0 \end{pmatrix} \right\}, \quad \mathfrak{p}^- = \left\{ \begin{pmatrix} 0 & -\eta & 0 \\ 0 & 0 & 0 \\ \eta^t & v & 0 \end{pmatrix} \right\}.
\]

We can now express explicitly the Harish-Chandra decomposition for \( \text{Osp}(m|2n) \), proven in Prop. 4.22.

Let \( P^- \) and \( P^+ \) be the complex subsupergroups of the complex orthosymplectic supergroup \( \text{Osp}(m|2n) \) defined via their functor of points as:

\[
P^+ = \left\{ \begin{pmatrix} 1 & 0 & \xi \\ \xi^t & 1 & u \\ 0 & 0 & 1 \end{pmatrix} \right\}, \quad P^- = \left\{ \begin{pmatrix} 1 & -\eta & 0 \\ 0 & 1 & 0 \\ \eta^t & v & 1 \end{pmatrix} \right\}
\]

Most immediately \( \mathfrak{p}^\pm = \text{Lie}(P^\pm) \). Notice that while in the ordinary setting we have that the groups \( \tilde{P}^\pm \) are abelian, in the supersetting, this is no longer true.

By Prop. 4.22 we have that the supermanifold \( P^- K P^+ \) is open in \( \text{Osp}(m|2n) \).

By its very construction \( D \) is a complex supermanifold and it has a natural action of \( \text{Osp}_D(m|2n) \). Notice that

\[
J \circ \text{ad}(X)|_{\mathfrak{p}_D} = \text{ad}(X)|_{\mathfrak{p}_D} \circ J
\]

with \( J \) the almost complex structure at the identity coset, \( J : \mathfrak{p}_D \to \mathfrak{p}_D \), where we identify \( \mathfrak{p}_D = T_{K_D}(\text{Osp}_D(m|2n)/K_D) \).
Proposition 4.41. Let \( J = \text{ad}(c)|_{\text{osp}(m|n)_0} + \text{ad}(2c)|_{\text{osp}(m|n)_1} \), where \( c \) is the element in the center of \( \frak{k}_D \):
\[
c = \begin{pmatrix}
0 & 0 & 0 \\
0 & i/2 & 0 \\
0 & 0 & -i/2
\end{pmatrix}
\]
Then \( J|_{\frak{p}_D} \) defines a complex structure on \( \frak{p}_D \), which corresponds to the \( \widetilde{\text{Osp}}_{\text{D}}(m|2n) \) invariant complex structure on \( \text{Osp}_\text{D}(m|2n)/K_\text{D} \), as in Prop. 4.24.
