Abstract

Objective: Resistance to antibiotics most especially third generation cephalosporins has assumed a worrisome dimension globally. Genes conferring these resistance which are mediated by enzymes known as extended spectrum beta-lactamases (ESBLs) are now wide spread among several Enterobacteriaceae species. However there is paucity of data regarding the distribution of these genes in Burkina Faso. Hence this prospective study aims to determine the prevalence and distribution of ESBL encoding genes in ESBL producing Enterobacteriaceae strains isolated from clinical samples of patients attending the three major hospitals in Ouagadougou Burkina Faso.

Results: ESBL-encoding genes were assayed in 187 ESBL producing Enterobacteriaceae strains. Among these isolates, the prevalence of ESBL-producing strains with blaTEM, blaSHV and blaCTX-M genes were 26.2% (49/187), 5.9% (11/187) and 40.1% (75/187) respectively. The association of ESBL encoding genes with health centers was statistically significant (p = 0.0209). Approximately 39.6% of E. coli harbored CTX-M and Klebsiella spp. 5.9%. This study demonstrates the dissemination of TEM, SHV and CTX-M genes in ESBL producing Enterobacteriaceae strains in Ouagadougou. Continuous spread of these bacteria poses great public health risk, thus increased surveillance and regulation of antibiotics use is imperative in Burkina Faso.

Keywords: Extended spectrum beta-lactamase, bla-TEM, bla-SHV, bla-CTX-M, Burkina Faso

Introduction

The problem of microbial drug resistance has assumed a global dimension and an alarming magnitude, being one of the leading unresolved problems in public health [1]. Beta-lactam antibiotics (penicillins, cephalosporins, monobactams and carbapenems) are among the most prescribed drugs in the world [2]. Their use is followed by resistance observed in several Enterobacteriaceae species [3]. Mechanism of resistance includes: topoisomerase mutation by reducing antibiotic affinity, activation of efflux system which expels antibiotics out of the cell and antibiotic inactivation by enzymes [4, 5]. A key mechanism of note is the production of β-lactamase that hydrolyzes the β-lactam ring [6, 7]. Broad spectrum beta-lactamasases are enzymes that have the particularity to hydrolyze all beta-lactams including third-generation cephalosporins except cephamycins and carbapenems [8, 9]. The number of extended-spectrum beta-lactamasases producing Enterobacteriaceae isolates (ESBL) has been on the increase in recent times worldwide [10]. Several antibiotic resistance genes studies have been carried out in Burkina Faso [11–14], but they are all restricted to single health centers in Ouagadougou city. Hence the aim of this study is to determine the prevalence and distribution of ESBL encoding genes in ESBL producing Enterobacteriaceae strains isolated from clinical samples of patients attending the three major hospitals in Ouagadougou Burkina Faso.
of resistance genes coding for broad spectrum beta-lactamases in the three major health centers of Ouagadougou, Burkina Faso. Since hospitals in recent years has been considered as reservoirs of ESBL producing Enterobacteriaceae [15].

**Main text**

Bacterial strains consisted of isolates obtained from our previous report [16]. They were obtained from patients attending three major hospitals Yalgado Ouedraogo Teaching Hospital (CHU-YO), Charles De Gaulle Paediatric Teaching Hospital (CHUP-CDG) and Saint Camille Hospital (HOSCO) in Ouagadougou Burkina Faso. Isolates were obtained from urine samples, pus samples, blood samples, stool samples, vaginal swab samples and pleural fluid samples.

**Methodology**

Genomic DNA was extracted according to Guedda et al. [17] with slight modification. One to five bacterial colonies were suspended in 100 µL of nuclease free water and suspension was heated at 100 °C for 10 min. After centrifugation at 12,000 × g for 10 min at 4 °C, 5 µL of supernatant were used as template in a 50 µL PCR reaction [18]. Resistance genes blaTEM, blaCTX-M, blaSHV were detected by PCR. PCR was performed in a final volume of 50 µL using the set of primers shown in Table 1. The reaction mix consist of 5× colored buffer 5 µL and 5× unshaded buffer, 3 µL of MgCl2 (25 mM) (Promega, USA), 0.5 µL of dNTP (10 mM), 0.5 µL of each primer (20 mM) (Sigma Genesys) and 0.2 µL of Taq polymerase (GoTaq® G2 Flexi DNA polymerase, USA, Reference M7805) with a volume of 5 µL of DNA. PCR amplification conditions of 30 cycles of initial denaturation 94 °C for 5 min, denaturation 94 °C for 1 min, annealing at 50 °C for 1 min (bla-TEM) and 60 °C for 1 min (bla-SHV and bla-CTX-M), elongation 72 °C for 1 min and final elongation for 72 °C for 7 min were carried out in a thermal cycler (GeneAmp® Applied Biosystem). Amplicons were electrophoresed on 1.5% agarose gel containing TAE buffer at 135 V for 30 min (90 mMTris, 90 mM acetate, 2 mM EDTA, pH 8.0) (TAE Buffer, USA) with DNA Ladder 1 kb (Promega, USA). Four bacteria strains were used as positive controls Salmonella spp. (U2A1446) for bla-TEM and bla-SHV, E. coli (U2A1790) for bla-CTX-M group 1, E. coli (U2A1799) for bla-CTX-M group 2 and E. coli (U2A1796) for bla-CTX-M-9 and DNA free reaction mixture as negative controls. Data obtained were entered and analyzed using Excel and GraphPad Prism version 5.01 software. A p-value less than 0.05 was considered to be statistically significant (p < 0.05).

**Results**

Phenotypic profile of ESBL producing isolates is shown in Fig. 1. A combination of resistance genes from various bacterial species were observed as shown in Table 2. The occurrence of blaCTX-M gene, blaTEM gene and blaSHV gene in E. coli was 39.6, 24.6 and 3.7% respectively compared to Klebsiella spp. that had 5.9% blaCTX-M gene, 2.7% blaTEM and 1.6% blaSHV gene occurrence. blaTEM-1 gene was found in all 3 health centers whereas CTX-M-9 was detected in bacteria isolated from CHU-YO. blaSHV-1, blaCTX-M-1 and blaCTX-M-2 genes were detected in bacteria isolated from CHU-YO and CHUP-CDG. blaCTX-M-9 gene was detected in Proteus sp. strain isolated from CHU-YO. However, a combination of 3 bla genes were detected in only isolates from CHU-YO and two bla genes were detected in isolates from CHU-YO and CHUP-CDG. Association of ESBL encoding genes with health centers was significant (p = 0.0209).

| Table 1 Sequences of primers used |
|-----------------------------------|
| Genes    | Primers | Sequence (5′–3′) | Weight (pb) | Accession number |
|-----------|---------|-----------------|-------------|-----------------|
| blaTEM    | a 216 (+) | ATAAAAATTCTTGAAAGAGCGAAA | 1079 | AB282997 |
|           | a 217 (−) | GACAGTTACCAATGCTTATCA |        |                 |
| blaSHV    | os-5 (+) | ATTTGTCGCCCTTTTACTCGC | 1051 | X98098 |
|           | os-6 (−) | TTATATGCGGCTATATGACC |        |                 |

|           | ctxM9 (−) | CCGTTGCGGATGATTCT |        |                 |
The presence of ESBL-producing bacteria in hospitals poses a serious challenge. This challenge cuts across developed and developing countries. In a multicenter study carried out in 18 representative hospitals in France, it was revealed that ESBL encoding genes including CTX-M-15, CTX-M-1, CTX-M-14 and SHV-12 were most prevalent [19]. Hospitals in Burkina Faso are no exception to this fact. In our study two major Enterobacteriaceae E. coli and Klebsiella spp. bearing various ESBL encoding genes dominated in all three major hospitals in Ouagadougou. This concurs with the findings of Najjuka et al. [20] that reported high prevalence of ESBL-producing E. coli and K. pneumoniae isolated from clinical samples in Uganda. Mathlouthi et al. [21] reported the distribution of blaCTX-M-15 (51.7%), blaTEM-1 (35.6%) and variants of blaSHV (21.8%) in Klebsiella spp. and E. coli stains isolated from hospitals in Tunisia and Libya. This is similar to our findings, however with lower percentage occurrence of bla genes in both E. coli (39.6% blaCTX-M, 24.6% blaTEM, and 3.7% blaSHV) and Klebsiella spp. (5.9% blaCTX-M, 2.7% blaTEM, and 1.6% blaSHV). This does not make the challenge in treatment and management of infection caused by these bacteria in Burkina Faso any lesser. In a similar study in Burkina Faso Ouedraogo et al. [14] reported CTX-M-1 group as dominant followed by CTX-M-9 group, this corroborate our findings with CTX-M-1 and CTX-M-2 dominating in two of the hospitals (CHU-YO and CHUP-CDG). This is in line with the reports of Ibrahim et al., Cantón et al. and Poirel et al. [22–24] that, bla-CTX-M genes

**Table 2** Distribution of resistance genes blaTEM, blaSHV, blaCTX-M according to the health center

| Enterobacteriaceae strains (n/N) | Resistance genes |
|----------------------------------|------------------|
| Yalgado Ouedraogo University Hospital (CHU-YO) | |
| K. pneumoniae (1/5) | TEM-1 |
| K. pneumoniae (2/5) | SHV-1 |
| K. pneumoniae (1/5) | CTX-M-1 |
| K. pneumoniae (1/5) | CTX-M-2 |
| K. pneumoniae (1/5) | TEM-1 + CTX-M-1 |
| K. pneumoniae (1/5) | TEM-1 + CTX-M-2 |
| K. pneumoniae (1/5) | CTX-M-1 + CTX-M-2 |
| K. oxytoca (1/1) | SHV-1 |

are the most common types of ESBL in microorganisms in most areas in the world while there seems to have been a drastic decrease of blaSHV. These identified genes play a major role in conferring resistance to extended-spectrum cephalosporins and other β-lactam antibiotics as exemplified in the results of our study. Ninety-three percent (93%) of isolates were resistant to cefepime, 96.8% resistant to cefotaxime, 96.8% resistant to ceftriaxone and 23% resistant to cefoxitine. However no isolate was resistant to imipenem a carbapenem. This corroborates the findings of El bouamri et al. [25] who reported E. coli armed with ESBL encoding genes that were resistant to cefotaxime, ceftazidime, cefepime and other β-lactam antibiotics but none was resistant to imipenem. The significance (p < 0.05) of ESBL encoding genes in strains isolated from health centers implies that hospitals remain a key hub in the potential dissemination of ESBL-producing Enterobacteriaceae. This is in line with the findings of Ahmed et al. [26] that detected bla-SHV and bla-CTX-M genes in Klebsiella pneumoniae isolates from patients with suspected nosocomial infections in Egypt.

Conclusions
The emergence, dissemination and expansion of ESBL-producing Enterobacteriaceae poses a serious public health challenges resulting in substantial limitations in the efficacy of therapeutic interventions. Hence prevention and proactive surveillance of antimicrobial resistance is crucial. Furthermore according to Zahar et al. [27] screening strategies should be established for early identification of patients that are carriers of ESBL producing bacteria in hospitals. Prescription of imipenem should be done with caution and monitored as it remains a viable option in a situation of overwhelming resistance of Enterobacteriaceae to other classes of routinely used antibiotics.

Limitations
This study enrolled patients attending only hospitals located in Ouagadougou Burkina Faso. Future Study should cover other hospitals across the country to determine entire country wise prevalence.
