ANALYSIS OF THE VECTOR TETRAQUARK STATES WITH P-WAVES BETWEEN THE DIQUARKS AND ANTIQUARKS VIA THE QCD SUM RULES

Zhi-Gang Wang

Department of Physics, North China Electric Power University, Baoding 071003, P. R. China

Abstract

In this article, we introduce a P-wave between the diquark and antidiquark explicitly to construct the vector tetraquark currents, and study the vector tetraquark states with the QCD sum rules systematically, and obtain the lowest vector tetraquark masses up to now. The present predictions support assigning the Y(4220/4260), Y(4320/4360), Y(4390) and Z(4250) to be the vector tetraquark states with a relative P-wave between the diquark and antidiquark pair.

Key words: Tetraquark state, QCD sum rules

1 Introduction

The attractive interactions induced by one-gluon exchange favor formation of the diquarks in color antitriplet, flavor antitriplet and spin singlet [1]. The diquarks εijk 3γCTqik have five structures in Dirac spinor space, where the i, j and k are color indexes, CT = Cγ5, C, Cγµγ5, Cγµ and Cσµν for the scalar, pseudoscalar, vector, axialvector and tensor diquarks, respectively. The favored or stable configurations are the scalar and axialvector diquark states from the QCD sum rules [2, 3, 4, 5]. In the non-relativistic quark model, an additional P-wave can change the parity by contributing a factor (−)L = −, where L = 1 is the angular momentum. The Cγ5 and Cγµ diquark states have the spin-parity J P = 0 + and 1 +, respectively, while the C and Cγµγ5 diquark states have the spin-parity J P = 0 − and 1 −, respectively. We can take the C and Cγµγ5 diquark states as the P-wave excitations of the Cγ5 (or Cγα) and Cγµ diquark states, respectively, the net effects of the P-waves are embodied in the underlined γ5 in the Cγαγ5. We can also introduce the P-wave explicitly in the Cγ5 and Cγµ diquark states and obtain the vector diquark states εijk 3γCTγ5 3qik or the tensor diquark states εijk 3γCTγµ 33∂µqik, where the derivative∂µ = 3∂µ − qik embodies the P-wave effects. Thereafter, we will refer the Cγ5, Cγµ diquark states as the S-wave diquark states and the C, Cγµγ5, Cγµγ5 33∂µ, Cγµ 33∂µ diquark states as the P-wave diquark states.

We can take the Cγ5 and Cγµ diquark states and antitriplet states as the basic constituents to construct the scalar, axialvector and tensor tetraquark states, for example, the Cγ5 ⊗ γαC, Cγα ⊗ γ5C type scalar tetraquark states [11], the Cγµ ⊗ γ5C ± Cγ5 ⊗ γµC type axialvector tetraquark states [12, 13], the Cγµ ⊗ γαC + Cγν ⊗ γµC type tensor tetraquark states [14].

We can take a S-wave and a P-wave diquark-antidiquark pair to construct the vector tetraquark states, or introduce an explicit P-wave in the S-wave diquark-antidiquark pair to construct the vector tetraquark states [15]. Experimentally, the Y(4260) observed by the BaBar collaboration [6], the Y(4220), Y(4390) and Y(4320) observed by the BESIII collaboration [7, 8], the Y(4360), Y(4630) observed by the Belle collaboration [9, 10] are excellent candidates for the vector tetraquark states. According to the analogous masses and widths, the Y(4260) and Y(4220) maybe the same particle, the Y(4360) and Y(4320) maybe the same particle, the Y(4660) and Y(4630) maybe the same particle. In Table 1, we present the possible assignments of the Y states as vector tetraquark states based on the QCD sum rules [16, 17, 18, 19, 20, 21, 22, 23]. In Refs. [16, 17, 18], the same interpolating currents lead to quite different assignments, because different input parameters

1 E-mail: zgwang@aliyun.com.
are chosen at the QCD side of the QCD sum rules. In the QCD sum rules for the hidden-charm (or hidden-bottom) tetraquark states and molecular states, the integrals
\[ \int_{4m_Q^2(s)}^{s_0} ds \rho_{QCD}(s, \mu) \exp \left( -\frac{s}{T^2} \right), \] (1)
are sensitive to the heavy quark masses \( m_Q \), where the \( \rho_{QCD}(s, \mu) \) are the QCD spectral densities, the \( T^2 \) are the Borel parameters, the \( s_0 \) are the continuum thresholds parameters. Variations of the heavy quark masses or the energy scales \( \mu \) lead to variations of integral ranges \( 4m_Q^2 - s_0 \) of the variable \( ds \) besides the QCD spectral densities \( \rho_{QCD}(s, \mu) \), therefore variations of the Borel windows and predicted masses and pole residues. In Refs.\[19, 24\], we suggest an energy scale formula
\[ \mu = \sqrt{M_{X/Y/Z}^2 - (2M_Q)^2} \] with the effective Q-quark masses \( M_Q \) to determine the ideal energy scales of the QCD spectral densities. Compared to the old predictions in Ref.\[19\], the new predictions based on detailed analysis with the updated parameters are preferred \[18\]. The \( C\gamma_5 \otimes \partial_\mu \otimes \gamma_5 C \) type interpolating currents chosen in Refs.\[21, 22\] have no definite charge conjugation.

In Ref.\[23\], we construct the \( C\gamma_5 \otimes \partial_\mu \otimes \gamma_5 C \) type interpolating current with \( J^{PC} = 1^{--} \) to study the lowest vector tetraquark state with the QCD sum rules by carrying out the operator product expansion up to the vacuum condensates of dimension 10, and use the modified energy scale formula
\[ \mu = \sqrt{M_{X/Y/Z}^2 - (2M_e + 0.5 \text{GeV})^2} = \sqrt{M_{X/Y/Z}^2 - (4.1 \text{GeV})^2} \] to determine the ideal energy scale of the QCD spectral density, where we have assumed that an additional P-wave costs about 0.5 GeV.

In the four-quark system \( q\bar{Q}q'\bar{Q}' \), the \( Q \)-quark serves as a static well potential and attracts the light quark \( q \) to form a heavy diquark in color antitriplet, while the \( \bar{Q} \)-quark serves as another static well potential and attracts the light antiquark \( \bar{q}' \) to form a heavy antiquark in color triplet \[19, 25\]. The diquark and antidiquark attract each other to form a compact tetraquark state \[19, 24\], the two heavy quarks \( Q \) and \( \bar{Q} \) stabilize the tetraquark state, just like the \( \mu^+ \) and \( \mu^- \) stabilize the \( \mu^+e^- - \mu^-e^+ \) system \[26\]. The tetraquark states are characterized by the effective heavy quark masses \( M_Q \) and the virtuality \( V = \sqrt{M_{X/Y/Z}^2 - (2M_Q)^2} \). If there is an additional P-wave between the diquark and antidiquark, in other words, between the heavy quark \( Q \) and heavy antiquark \( \bar{Q} \), the virtuality should be modified to be
\[ V = \sqrt{M_{X/Y/Z}^2 - (2M_Q + 0.5 \text{GeV})^2}, \]
therefore the energy scale formula \( \mu = V \) is also modified. For the \( C\gamma_5 \otimes \gamma_5 C \)-type and \( C \otimes \gamma_5 C \)-type vector tetraquark states, the relative P-waves lie in the P-wave diquarks or antidiquarks, not lie between the diquark and antidiquark, the energy scale formula
\[ \mu = \sqrt{M_{X/Y/Z}^2 - (2M_Q)^2} \] works \[18, 19, 20\].

In this article, we extend our previous work \[23\] to study other vector tetraquark states with an explicit relative P-wave between the diquark and antidiquark with the QCD sum rules in a systematic way. In the type-II diquark-antidiquark model \[27\], L. Maiani et al assign the \( Y(4008) \), \( Y(4260) \), \( Y(4290/4220) \) and \( Y(4630) \) to be the four ground states with \( L = 1 \) based on the effective Hamiltonian with the spin-spin and spin-orbit interactions by neglecting the spin-spin interactions between the quarks and antiquarks. In Ref.\[28\], A. Ali et al incorporate the dominant spin-spin, spin-orbit and tensor interactions, and observe that the preferred assignments of the ground state tetraquark states with \( L = 1 \) are the \( Y(4220), Y(4330), Y(4390), Y(4660) \). In the diquark-antidiquark model, the quantum numbers of the \( Y \) states are shown explicitly in Table 2, where the \( L \) is the angular momentum between the diquark and antidiquark, \( \vec{S} = \vec{S}_{qc} + \vec{S}_{q\bar{q}} \), \( \vec{J} = \vec{S} + \vec{L} \). In this article, we reexamine those assignments based on the QCD sum rules, which is a powerful theoretical tool in studying the exotic \( X, Y, Z \) particles. In the QCD sum rules, the input parameters are the vacuum condensates and quark masses, which have universal values.
In the isospin limit, the vector tetraquark states with the symbolic quark constituents

\[ I = 1 : \quad c\bar{c}u\bar{d}, \quad c\bar{c}u\bar{u} - d\bar{d} \sqrt{2}, \quad c\bar{c}d\bar{u}, \]

\[ I = 0 : \quad c\bar{c}u\bar{u} + d\bar{d} \sqrt{2}, \]  

have degenerate masses. In this article, we study the \( c\bar{c}u\bar{d} \) tetraquark states for simplicity. Now we construct the interpolating currents according the quantum numbers shown in Table 2,

\[
J^1_\mu(x) = \frac{\varepsilon^{ijk}\epsilon^{imn}}{\sqrt{2}} u^T_j(x) C\gamma_5 c^k(x) \gamma^\mu \bar{d}^m(x) \gamma_5 C\bar{c}^{Tn}(x), \\
J^2_\mu(x) = \frac{\varepsilon^{ijk}\epsilon^{imn}}{\sqrt{2}} u^T_j(x) C\gamma_\alpha c^k(x) \gamma^\mu \bar{d}^m(x) \gamma^\alpha \gamma_5 C\bar{c}^{Tn}(x), \\
J^3_\mu(x) = \frac{\varepsilon^{ijk}\epsilon^{imn}}{2} \left[ u^T_j(x) C\gamma_\alpha c^k(x) \gamma^\mu \bar{d}^m(x) \gamma^\alpha \gamma_5 C\bar{c}^{Tn}(x) \\
+ u^T_j(x) C\gamma_5 c^k(x) \gamma^\mu \bar{d}^m(x) \gamma_5 C\bar{c}^{Tn}(x) \right], \\
J_{\mu\nu}(x) = \frac{\varepsilon^{ijk}\epsilon^{imn}}{2\sqrt{2}} \left[ u^T_j(x) C\gamma_5 c^k(x) \gamma^\mu \bar{d}^m(x) \gamma_5 C\bar{c}^{Tn}(x) \\
+ u^T_j(x) C\gamma_\alpha c^k(x) \gamma^\mu \bar{d}^m(x) \gamma^\alpha \gamma_5 C\bar{c}^{Tn}(x) \\
+ u^T_j(x) C\gamma_\alpha c^k(x) \gamma^\nu \bar{d}^m(x) \gamma^\mu \gamma_5 C\bar{c}^{Tn}(x) \\
+ u^T_j(x) C\gamma_\alpha c^k(x) \gamma^\nu \bar{d}^m(x) \gamma^\nu \gamma_5 C\bar{c}^{Tn}(x) \right].
\]

Table 1: The OPE denotes truncations of the operator product expansion up to the vacuum condensates of dimension \( n \), the No denotes the vacuum condensates of dimension \( n' \) are not included.

In this article, we choose the currents \( J^1_\mu(x), J^2_\mu(x), J^3_\mu(x) \) and \( J_{\mu\nu}(x) \) to study the vector tetraquark states with the QCD sum rules systematically by calculating the vacuum condensates up to dimension 10 in a consistent way in the operator product expansion, and use the modified energy scale formula \( \mu = \sqrt{M^2_{X/Y/Z} - (2M_\pi + 0.5 \text{ GeV})^2} = \sqrt{M^2_{X/Y/Z} - (4.1 \text{ GeV})^2} \) to determine the ideal energy scales of the QCD spectral densities, and reexamine the possible assignments of the \( Y \) states.

The article is arranged as follows: we derive the QCD sum rules for the masses and pole residues of the vector tetraquark states in section 2; in section 3, we present the numerical results and discussions; section 4 is reserved for our conclusion.
\[ \Pi_{\mu
u}(p) = i \int d^4xe^{ip\cdot x}\langle 0| T \{ J_\mu(x), J_\nu(0) \} | 0 \rangle, \]
\[ \Pi_{\mu\nu\alpha\beta}(p) = i \int d^4xe^{ip\cdot x}\langle 0| T \{ J_\mu(x), J_\nu(0) \} | 0 \rangle, \]

where \( J_\mu(x) = J_\mu^1(x), J_\nu^2(x) \) and \( J_\mu^3(x) \). Under charge conjugation transform \( \hat{C} \), the currents \( J_\mu(x) \) and \( J_{\mu\nu}(x) \) have the property,
\[ \hat{C} J_\mu(x) \hat{C}^{-1} = - J_\mu(x), \]
\[ \hat{C} J_{\mu\nu}(x) \hat{C}^{-1} = - J_{\mu\nu}(x), \]

the currents have definite charge conjugation.

At the phenomenological side, we can insert a complete set of intermediate hadronic states with the same quantum numbers as the current operators \( J_\mu(x) \) and \( J_{\mu\nu}(x) \) into the correlation functions \( \Pi_{\mu\nu}(p) \) and \( \Pi_{\mu\nu\alpha\beta}(p) \) respectively to obtain the hadronic representation \([29, 30]\). After isolating the ground state vector tetraquark contributions, we obtain the results,

\[ \Pi_{\mu\nu}(p) = \frac{\lambda_2^2}{M_2^2 - p^2} \left( -g_{\mu\nu} + \frac{p_\mu p_\nu}{p^2} \right) + \cdots, \]
\[ = \Pi_Y(p^2) \left( -g_{\mu\nu} + \frac{p_\mu p_\nu}{p^2} \right) + \cdots, \]
\[ \Pi_{\mu\nu\alpha\beta}(p) = \frac{\lambda_2^2}{M_2^2 (M_2^2 - p^2)} \left( p^2 g_{\mu\alpha} g_{\nu\beta} - p^2 g_{\mu\beta} g_{\nu\alpha} - g_{\mu\alpha} p_\nu p_\beta - g_{\mu\beta} p_\nu p_\alpha + g_{\mu\beta} p_\nu p_\alpha + g_{\alpha\nu} p_\mu p_\beta \right) \]
\[ + \frac{\lambda_2^2}{M_2^2 (M_2^2 - p^2)} \left( -g_{\mu\alpha} p_\nu p_\beta - g_{\mu\beta} p_\nu p_\alpha + g_{\mu\beta} p_\nu p_\alpha + g_{\mu\alpha} p_\nu p_\beta \right) \]
\[ = \Pi_Y(p^2) \left( p^2 g_{\mu\alpha} g_{\nu\beta} - p^2 g_{\mu\beta} g_{\nu\alpha} - g_{\mu\alpha} p_\nu p_\beta - g_{\mu\beta} p_\nu p_\alpha + g_{\mu\beta} p_\nu p_\alpha + g_{\alpha\nu} p_\mu p_\beta \right) \]
\[ + \Pi_Z(p^2) \left( -g_{\mu\alpha} p_\nu p_\beta - g_{\mu\beta} p_\nu p_\alpha + g_{\mu\beta} p_\nu p_\alpha + g_{\alpha\nu} p_\mu p_\beta \right). \]

where the pole residues \( \lambda_Y \) and \( \lambda_Z \) are defined by

\[ \langle 0 | J_\mu(0) | Y(p) \rangle = \lambda_Y \varepsilon_\mu, \]
\[ \langle 0 | J_{\mu\nu}(0) | Y(p) \rangle = \lambda_Y \frac{\varepsilon_{\mu\alpha\beta}}{M_Y} \varepsilon^{\alpha\beta}, \]
\[ \langle 0 | J_{\mu\nu}(0) | Z(p) \rangle = \frac{\lambda_Z}{M_Z} (\varepsilon_\mu p_\nu - \varepsilon_\nu p_\mu), \]

Table 2: The vector tetraquark states, possible assignments and the corresponding vector tetraquark currents, where the mixing effects are neglected.

## 2 QCD sum rules for the vector tetraquark states

In the following, we write down the two-point correlation functions \( \Pi_{\mu\nu}(p) \) and \( \Pi_{\mu\nu\alpha\beta}(p) \) in the QCD sum rules,
the $\varepsilon_\mu$ are the polarization vectors of the vector tetraquark states $Y$ and axialvector tetraquark states $Z$ with the $J^{PC} = 1^{--}$ and $1^{+-}$, respectively. Now we project out the components $\Pi_Y(p^2)$ and $\Pi_Z(p^2)$ by introducing the operators $P^{\mu\nu\alpha\beta}_Y$ and $P^{\mu\nu\alpha\beta}_Z$,

\begin{align}
\Pi_Y(p^2) &= p^2\bar{\Pi}_Y(p^2) = P^{\mu\nu\alpha\beta}_Y\Pi_{\mu\nu\alpha\beta}(p), \\
\Pi_Z(p^2) &= p^2\bar{\Pi}_Z(p^2) = P^{\mu\nu\alpha\beta}_Z\Pi_{\mu\nu\alpha\beta}(p),
\end{align}

where

\begin{align}
P^{\mu\nu\alpha\beta}_Y &= \frac{1}{6} \left( g^{\mu\alpha} - \frac{p^\mu p^\alpha}{p^2} \right) \left( g^{\nu\beta} - \frac{p^\nu p^\beta}{p^2} \right), \\
P^{\mu\nu\alpha\beta}_Z &= \frac{1}{6} \left( g^{\mu\alpha} - \frac{p^\mu p^\alpha}{p^2} \right) \left( g^{\nu\beta} - \frac{p^\nu p^\beta}{p^2} \right) - \frac{1}{6} g^{\mu\alpha} g^{\nu\beta}.
\end{align}

In this article, we choose the components $\Pi_Y(p^2)$ to study the vector tetraquark states.

At the QCD side, we carry out the operator product expansion up to the vacuum condensates of dimension-10, and take into account the vacuum condensates which are vacuum expectations of the operators of the orders $O(\alpha_s^k)$ with $k \leq 1$ consistently. For the technical details, one can consult Refs.\(^{[13, 23]}\). Once analytical expressions of the QCD spectral densities are obtained, we can take the quark-hadron duality below the continuum threshold $s_0$ and perform Borel transform with respect to the variable $P^2 = -p^2$ to obtain the QCD sum rules:

\begin{equation}
x^2_Y \exp\left( -\frac{M_Y^2}{T^2} \right) = \int^{\infty}_{4m_c^2} ds \rho(s) \exp\left( -\frac{s}{T^2} \right),
\end{equation}

where

\begin{align}
\rho(s) &= \rho_0(s) + \rho_3(s) + \rho_4(s) + \rho_5(s) + \rho_6(s) + \rho_7(s) + \rho_8(s) + \rho_{10}(s),
\end{align}

the subscripts $i$ in the spectral densities $\rho_i(s)$ denote the dimensions of the vacuum condensates,

\begin{align}
\rho_3(s) &\propto \langle \bar{q}q \rangle, \\
\rho_4(s) &\propto \langle \alpha_s G G \rangle, \\
\rho_5(s) &\propto \langle \bar{q}g_s \sigma G q \rangle, \\
\rho_6(s) &\propto \langle \bar{q}q \rangle^2, \\
\rho_7(s) &\propto \langle \bar{q}q \rangle \langle \alpha_s G G \rangle, \\
\rho_8(s) &\propto \langle \bar{q}q \rangle \langle \bar{q}g_s \sigma G q \rangle, \\
\rho_{10}(s) &\propto \langle \bar{q}g_s \sigma G q \rangle^2, \langle \bar{q}q \rangle^2 \langle \frac{\alpha_s G G}{\pi} \rangle,
\end{align}

the lengthy expressions of the QCD spectral densities are neglected for simplicity, the interested readers can obtain them through my E-mail. The relatively simple expressions of the QCD spectral densities for the current $J^1_\mu(x)$ are presented in Ref.\(^{[23]}\). For the currents $J^4_\mu(x)$ and $J^5_\mu(x)$, we take into account all the contributions $\rho_i(s)$ with $i = 0, 3, 4, 5, 6, 7, 8, 10$. In calculations, we observe that the contributions of the vacuum condensates $\langle \frac{\alpha_s G G}{\pi} \rangle, \langle \bar{q}q \rangle \langle \frac{\alpha_s G G}{\pi} \rangle$ and $\langle \bar{q}q \rangle^2 \langle \frac{\alpha_s G G}{\pi} \rangle$ play a minor important role in the Borel windows, the predicted masses are almost the same if we neglect their contributions, furthermore, they also play a minor important role in determining the Borel windows. So we neglect the contributions of the vacuum condensates $\langle \frac{\alpha_s G G}{\pi} \rangle, \langle \bar{q}q \rangle \langle \frac{\alpha_s G G}{\pi} \rangle$ and $\langle \bar{q}q \rangle^2 \langle \frac{\alpha_s G G}{\pi} \rangle$ in the QCD spectral densities for the currents $J^3_\mu(x)$ and $J^5_{\mu\nu}(x)$ due to the formidable calculations in the operator product expansion.
For the current $J_\mu(x) = J_\mu^1(x)$, the correlation function $\Pi_{\mu\nu}(p)$ can be written as

$$\Pi_{\mu\nu}(p) = -\frac{i\epsilon^{ijk}e^{inn'}e^{i'j'k'}e^{i'm'n'}}{2} \int d^4xe^{ip\cdot x}$$

$$\left\{ \begin{array}{c}
\left[ \gamma_5 C^{kk'}(x)\gamma_5 CS^{jj'}T(x)C \right] \partial_\mu \partial_\nu \left[ \gamma_5 C^{m'n'}(-x)\gamma_5 CS^{m'm'T}(-x)C \right] \\
-\partial_\mu \left[ \gamma_5 C^{kk'}(x)\gamma_5 CS^{jj'}T(x)C \right] \partial_\nu \left[ \gamma_5 C^{m'n'}(-x)\gamma_5 CS^{m'm'T}(-x)C \right] \\
-\partial_\nu \left[ \gamma_5 C^{kk'}(x)\gamma_5 CS^{jj'}T(x)C \right] \partial_\mu \left[ \gamma_5 C^{m'n'}(-x)\gamma_5 CS^{m'm'T}(-x)C \right] \\
+\partial_\nu \partial_\nu \left[ \gamma_5 C^{kk'}(x)\gamma_5 CS^{jj'}T(x)C \right] \left[ \gamma_5 C^{m'n'}(-x)\gamma_5 CS^{m'm'T}(-x)C \right]
\end{array} \right\}, \quad (18)$$

where the $S_{ij}(x)$ and $C_{ij}(x)$ are the full u/d and c quark propagators, respectively. In other words, $\Pi_{\mu\nu}(p) \propto \int d^4xe^{ip\cdot x} Tr[\cdots \times Tr[\cdots]$. The first $Tr[\cdots]$ contains quark lines for the diquark state, while the second $Tr[\cdots]$ contains quark lines for the antidiquark state. The contributions originate from the interactions between the quark lines in the first $Tr[\cdots]$ or in the second $Tr[\cdots]$ are factorizable, while the contributions originate from the interactions between the quark lines in the first $Tr[\cdots]$ and in the second $Tr[\cdots]$ are non-factorizable. In other words, the inner-diquark interactions are factorizable, while the inter-diquark interactions are non-factorizable. In Refs.\[31:32\], the authors assume that there exists a repulsive barrier with finite width between the diquarks and antidiquarks in the tetraquark states, which can answer satisfactorily some long standing questions challenging the diquark-antidiquark model of exotic resonances, for example, the non-observation of charged partners $X^\pm$ of the $X(3872)$ and the absence of a hyperfine splitting between two different neutral states, the tetraquark states decay more copiously into open flavor mesons rather than quarkonia. In the present work, we observe that the dominant contributions come from the factorizable interactions (or Feynman-diagrams), the non-factorizable interactions (or Feynman-diagrams) play a much less important role, which are consistent with the inter-diquark barrier introduced in Refs.\[31:32\]. The finite potential barrier between diquarks could make the tetraquark state metastable against collapse and fall apart decay, which happens if one of the quarks tunnels towards the other side. The non-factorizable interactions correspond to the tunneling effects in Refs.\[31:32\] qualitatively. The conclusion survives for other currents.

We derive Eq.(15) with respect to $\tau = \frac{1}{f_{\pi}^2}$, then eliminate the pole residues $\lambda_Y$, and obtain the QCD sum rules for the masses of the vector tetraquark states,

$$M_Y^2 = -\frac{\int_{4m_0^2}^{m_Y^2} ds \frac{d}{d\tau} \rho(s) \exp(-\tau s)}{\int_{4m_0^2}^{\infty} ds \rho(s) \exp(-\tau s)}.$$

### 3 Numerical results and discussions

We take the standard values of the vacuum condensates $\langle \bar{q}q \rangle = -(0.24 \pm 0.01 \text{ GeV})^3$, $\langle \bar{q}g_\sigma Gq \rangle = m_0^2 \langle \bar{q}q \rangle$, $m_0 = (0.8 \pm 0.1) \text{ GeV}$, $\langle \frac{G}{\pi} \rangle = (0.33 \text{ GeV})^4$ at the energy scale $\mu = 1 \text{ GeV}$, and choose the $\overline{MS}$ mass $m_c(m_c) = 1.275 \pm 0.025 \text{ GeV}$ from the Particle Data Group, and set $m_u = m_d = 0$. Moreover, we take into account the energy-scale dependence of the input.
parameters on the QCD side,

$$\langle \bar{q}q \rangle(\mu) = \langle \bar{q}q \rangle(Q) \left[ \frac{\alpha_s(Q)}{\alpha_s(\mu)} \right]^{\frac{12}{5}},$$

$$\langle \bar{q}g_s\sigma Gq \rangle(\mu) = \langle \bar{q}g_s\sigma Gq \rangle(Q) \left[ \frac{\alpha_s(Q)}{\alpha_s(\mu)} \right]^{\frac{2}{5}},$$

$$m_c(\mu) = m_c(m_c) \left[ \frac{\alpha_s(\mu)}{\alpha_s(m_c)} \right]^{\frac{12}{5}},$$

$$\alpha_s(\mu) = \frac{1}{b_0\mu} \left[ 1 - \frac{b_1 \log t}{b_0^2} + \frac{b_2 (\log^2 t - \log t - 1) + b_0 b_2}{b_0^2 \mu^2} \right]. \tag{20}$$

where $t = \log \frac{\mu^2}{\Lambda^2}$, $b_0 = \frac{33 - 2n_f}{12\pi^2}$, $b_1 = \frac{153 - 19n_f}{24\pi^2}$, $b_2 = \frac{2857 - 609n_f + 52n_f^2}{125\pi^2}$, $\Lambda = 210$ MeV, 292 MeV and 332 MeV for the flavors $n_f = 5$, 4 and 3, respectively \[34, 35\], and evolve all the input parameters to the ideal energy scales $\mu$ to extract the masses of the vector tetraquark states, in other words, choose the ideal energy scales $\mu$ to satisfy the relation $M^2_{X/Y/Z} = \mu^2 + (4.1 \text{ GeV})^2$ \[23\].

In Ref.\[35\], we study the $C\gamma_5 \otimes \gamma_\mu C - C\gamma_\mu \otimes \gamma_5 C$ type axialvector tetraquark states with the QCD sum rules in details, and observe that the $Z_c(3900)$ and $Z(4430)$ can be assigned to be the ground state and the first radial excited state of the axialvector tetraquark states with $J^{PC} = 1^{++}$, respectively \[27, 37\], the energy gap between the $Z(4430)$ and the $Z_c(3900)$ is 576 MeV. For more works on this subject via QCD sum rules, one can consult Ref.\[38\]. In Refs.\[39, 40\], we study the $C\gamma_\mu \otimes \gamma^\mu C$-type and $C\gamma_5 \otimes \gamma_5 C$-type $c\bar{c}b\bar{s}$ scalar tetraquark states with the QCD sum rules in a systematic way, and observe that the $X(3915)$ and $X(4500)$ can be assigned to be the ground state and the first radial excited state of the scalar tetraquark states respectively, the energy gap between the $X(4500)$ and the $X(3915)$ is 588 MeV. In this article, we will take the continuum threshold parameters as $\sqrt{s_0} = M_Y + (0.55 \pm 0.10) \text{ GeV}$.

Now we search for the ideal Borel parameters $T^2$ and continuum threshold parameters $s_0$ to satisfy the following four criteria:

1. Pole dominance at the phenomenological side;
2. Convergence of the operator product expansion;
3. Appearance of the Borel platforms;
4. Satisfying the modified energy scale formula,

via try and error, and obtain the Borel parameters or Borel windows $T^2$, continuum threshold parameters $s_0$, ideal energy scales of the QCD spectral densities, pole contributions of the ground states, and contributions of the vacuum condensates of dimension 10, which are shown explicitly in Table 3.

From Table 3, we can see that the pole dominance at the phenomenological side is well satisfied, the operator product expansion is well convergent. We take into account all uncertainties of the input parameters, and obtain the values of the masses and pole residues of the vector tetraquark states, which are shown explicitly in Table 4 and in Figs. 1-2. From Figs. 1-2, we can see that there appear platforms in the Borel windows. From Tables 3-4, we can see that the modified energy scale formula $\mu = \sqrt{M^2_{X/Y/Z} - (4.1 \text{ GeV})^2}$ can be well satisfied. Now the four criteria of the QCD sum rules are all satisfied, and we expect to make reliable predictions. In Fig. 1, we also plot the predicted masses of the tetraquark states $|0; 0; 0; 1; 1\rangle$ and $|1; 1; 0; 1; 1\rangle$ from the QCD sum rules without including the contributions of the vacuum condensates $\langle \bar{q}q \rangle \frac{\alpha_s(\mu)}{\pi}$, $\langle \bar{q}g_s\sigma Gq \rangle$ and $\langle \bar{q}q \rangle^2 \frac{\alpha_s(\mu)}{\pi}$, from the figure, we can see that those contributions can be neglected approximately in the Borel windows. The predicted masses of the tetraquark states $\sqrt{2} \langle (0; 0; 1; 1) + (0; 1; 1; 1) \rangle$ and $|1; 1; 2; 1; 1\rangle$ without including the contributions of the vacuum condensates $\langle \bar{q}q \rangle \frac{\alpha_s(\mu)}{\pi}$, $\langle \bar{q}g_s\sigma Gq \rangle$ and $\langle \bar{q}q \rangle^2 \frac{\alpha_s(\mu)}{\pi}$ are expected to be robust.

In Table 5, we present the possible assignments of the vector tetraquark states based on the QCD sum rules compared to the assignments suggested in Ref.\[28\].
with the experimental values $M_{Y}$ and $Y$ Particle Data Group [34], which supports assigning the $QCD$ spectral densities, pole contributions of the ground states, and contributions of the vacuum condensates of dimension 10.

| $|S_{qc}, S_{qar{c}}; S, L; J|$ | $M_{Y} (GeV)$ | $\lambda_{Y} (10^{-2}GeV^3)$ |
|----------------|-------------|------------------|
| $|0, 0; 0, 1; 1|$ | 4.24 ± 0.10 | 2.31 ± 0.45     |
| $|1, 1; 0, 1; 1|$ | 4.28 ± 0.10 | 4.93 ± 1.00     |
| $\sqrt{s_0} ((1, 0; 1, 1; 1) + [0, 1; 1, 1; 1])$ | 4.31 ± 0.10 | 2.99 ± 0.54     |
| $|1, 1; 2, 1; 1|$ | 4.33 ± 0.10 | 7.35 ± 1.39     |

The predicted mass $M_{Y} = 4.24 ± 0.10 GeV$ of the $|0, 0; 0, 1; 1|$ tetraquark state is in excellent agreement with the experimental value $M_{Y}(4220) = 4222.0 ± 3.1 ± 1.4 MeV$ from the BESIII collaboration [8], or the experimental value $M_{Y}(4260) = 4230.0 ± 8.0 MeV$ from Particle Data Group [34], which supports assigning the $Y(4260/4220)$ to be the $C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C$ type vector tetraquark state.

The predicted mass $M_{Y} = 4.28 ± 0.10 GeV$ of the $|1, 1; 0, 1; 1|$ tetraquark state is compatible with the experimental values $M_{Y}(4220) = 4222.0 ± 3.1 ± 1.4 MeV$ and $M_{Y}(4230) = 4320.0 ± 10.4 ± 7.0 MeV$ from the BESIII collaboration [8], or the experimental values $M_{Y}(4260) = 4230.0 ± 8.0 MeV$ and $M_{Y}(4360) = 4368.0 ± 13.0 MeV$ from Particle Data Group [34], which supports assigning the $Y(4260/4220)$ or the $Y(4360/4320)$ to be the $C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C$ type vector tetraquark state.

The predicted masses $M_{Y} = 4.31 ± 0.10 GeV$ of the $\frac{1}{\sqrt{2}}([1, 0; 1, 1; 1] + [0, 1; 1, 1; 1])$ tetraquark state and $M_{Y} = 4.33 ± 0.10 GeV$ of the $|1, 1; 2, 1; 1|$ tetraquark state are compatible with the experimental values $M_{Y}(4320) = 4320.0 ± 10.4 ± 7.0 MeV$ and $M_{Y}(4390) = 4391.6 ± 6.3 ± 1.0 MeV$ from the BESIII collaboration [8], or the experimental value $M_{Y}(4360) = 4368.0 ± 13.0 MeV$ from Particle Data Group [34], which supports assigning the $Y(4360/4320)$ or the $Y(4390)$ to be the $C\gamma_{5} \otimes \gamma_{5} C + C\gamma_{5} \otimes \gamma_{5} C$ type vector tetraquark state or the $C\gamma_{5} \otimes \gamma_{5} C + C\gamma_{5} \otimes \gamma_{5} C - C\gamma_{5} \otimes \gamma_{5} C + C\gamma_{5} \otimes \gamma_{5} C$ type vector tetraquark states.

The present predictions disfavor assigning the $Y(4660)$ to be the $C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C$ type, $C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C$ type, $C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C + C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C$ type or $C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C - C\gamma_{5} \otimes \gamma \otimes \gamma_{5} C$ type vector tetraquark states. While in Ref. [28], the $Y(4660)$ is assigned to be tetraquark state $|1, 1; 2, 1; 1|$ by fitting the experimental values of the masses with the diquark-antidiquark model. Our previous calculations based on the QCD sum rules indicate that the $Y(4660)$ can be assigned to be the $C\otimes \gamma_{5} C$ type vector tetraquark state $\bar{c}\bar{c}ss$ [18] or the $C\gamma_{5} \otimes \gamma_{5} C - C\gamma_{5} \otimes \gamma_{5} C$ type vector tetraquark state $\bar{c}\bar{c}q\bar{q}$ [20], where the relative P-waves lie in the diquarks or antidiquarks.

In 2008, the Belle Collaboration observed two resonance-like structures ($Z(4050)$ and $Z(4250)$) in the $\pi^{+}\chi_{c1}$ invariant mass distribution in the exclusive $B^{0} \rightarrow K^{-}\pi^{+}\chi_{c1}$ decays with the statistical significances exceeds 5$\sigma$, including the effects of systematics from various fit models [41]. The
Table 5: The masses of the vector tetraquark states and possible assignments.

| $|S_{qc}, \bar{S}_{\bar{q}c}; S, L; J\rangle$ | $M_V($GeV$)$ | This Work | Ref. |
|---------------------------------------------|-----------------|------------|------|
| $|0, 0; 0, 1; 1\rangle$                     | 4.24 ± 0.10     | $Y(4220)$ |      |
| $\frac{1}{\sqrt{2}} (|1, 0; 1, 1; 1\rangle + |0, 1; 1, 1\rangle)$ | 4.31 ± 0.10     | $Y(4320/4390)$ | $Y(4330)$ |
| $|1, 1; 0, 1; 1\rangle$                     | 4.28 ± 0.10     | $Y(4220/4320)$ | $Y(4390)$ |
| $|1, 1; 2, 1; 1\rangle$                     | 4.33 ± 0.10     | $Y(4320/4390)$ | $Y(4660)$ |

Figure 1: The masses of the vector tetraquark states with variations of the Borel parameters $T^2$, where $A$, $B$, $C$ and $D$ denote the $|0, 0; 0, 1; 1\rangle$, $|1, 1; 0, 1; 1\rangle$, $\frac{1}{\sqrt{2}} (|1, 0; 1, 1; 1\rangle + |0, 1; 1, 1\rangle)$ and $|1, 1; 2, 1; 1\rangle$ vector tetraquark states, respectively, the "No GG" denotes the contributions of the vacuum condensates $\langle \frac{\alpha_s}{\pi} GG \rangle$, $\langle \bar{q}q \rangle \langle \frac{\alpha_s}{\pi} GG \rangle$ and $\langle \bar{q}q \rangle^2 \langle \frac{\alpha_s}{\pi} GG \rangle$ are excluded.
Figure 2: The pole residues of the vector tetraquark states with variations of the Borel parameters $T^2$, where the $A$, $B$, $C$ and $D$ denote the $|0,0;0,1⟩$, $|1,1;0,1;1⟩$, $\frac{1}{\sqrt{2}} (|1,0;1,1⟩ + |0,1;1,1⟩)$ and $|1,1;2,1⟩$ vector tetraquark states, respectively.
Breit-Wigner masses and widths are \( M_{Z(4050)} = 4051 \pm 14^{+20}_{-41} \) MeV, \( \Gamma_{Z(4050)} = 82^{+21}_{-17} + 20^{+47}_{-22} \) MeV, \( M_{Z(4250)} = 4248^{+44+180}_{-29-35} \) MeV and \( \Gamma_{Z(4250)} = 177^{+54+316}_{-39-61} \) MeV, respectively. If the \( Z(4050) \) and \( Z(4250) \) are really resonances, their quark contents must be \( \bar{c}d\bar{c}u \) according to the non-zero electronic charge. If the \( Z(4050) \) and \( Z(4250) \) are scalar tetraquark states, the decays \( Z(4050/4250) \rightarrow \pi^+ \chi_{c1} \) take place through the relative P-wave; on the other hand, if they are vector tetraquark states, the decays take place through the relative S-wave. The predicted masses \( 4.24 \pm 0.10 \) GeV, \( 4.31 \pm 0.10 \) GeV, \( 4.28 \pm 0.10 \) GeV and \( 4.33 \pm 0.10 \) GeV for the vector tetraquark states \( |0, 0; 0, 1; 1, 0; 1, 1, 1, 1\rangle, |1, 1; 0, 1; 1, 1, 1, 1\rangle, |1, 1, 1; 0, 1; 1, 1, 1, 1\rangle \) and \( |1, 1, 1, 1; 0, 1; 1, 1, 1, 1\rangle \) respectively are all consistent with the experimental data \( M_{Z(4250)} = 4248^{+44+180}_{-29-35} \) MeV from the Belle Collaboration considering the large uncertainties. The present predictions support assigning the \( Z(4250) \) to the vector tetraquark state with a relative P-wave between the diquark and antidiquark pair.

We cannot identify a particle unambiguously with the mass alone, we have to study the decays of the \( Y(4260/4220), Y(4360/4320), Y(4390) \) and \( Y(4660/4630) \) with the QCD sum rules to testify the assignments in the scenario of the tetraquark states, it is our next work. Experimentally, a number of decays of the \( Y(4260/4220), Y(4360/4320), Y(4390) \) and \( Y(4660/4630) \) have been observed, such as

\[
Y(4220) \rightarrow \omega \chi_{c0}, J/\psi \pi^+ \pi^-, h_c \pi^+ \pi^-,
Y(4260) \rightarrow X(3872) \gamma, Z_c(3900)^+ \pi^-,
Y(4320) \rightarrow J/\psi \pi^+ \pi^-, \psi' \pi^+ \pi^-,
Y(4390) \rightarrow h_c \pi^+ \pi^-,
Y(4660) \rightarrow \psi' \pi^+ \pi^-, \Lambda_c^+ \Lambda_c^-.
\]  

(21)

For detailed reviews on the properties of the \( X, Y, Z \) states, one can consult the Refs. [42, 43].

4 Conclusion

In this article, we introduce the relative P-wave between the diquark and antidiquark explicitly to construct the vector tetraquark currents, then carry out the operator product expansion up to the vacuum condensates of dimension 10, take the modified energy scale formula to determine the optimal energy scales of the QCD spectral densities, and study the masses and pole residues of the vector tetraquark states with the QCD sum rules systematically. We obtain the lowest vector tetraquark masses up to now, the present predictions support assigning the \( Y(4220/4260), Y(4320/4360), Y(4390) \) and \( Z(4250) \) to be the vector tetraquark states with a relative P-wave between the diquark and antidiquark pair.
