Hybrid Routhian reduction for simple hybrid forced Lagrangian systems

María Emma Eyrea Irazú, Asier López-Gordón, Manuel de León, Leonardo J. Colombo

Abstract—This paper discusses Routh reduction for simple hybrid forced mechanical systems. We give general conditions on whether it is possible to perform symmetry reduction for a simple hybrid Lagrangian system subject to non-conservative external forces, emphasizing the case of cyclic coordinates. We illustrate the applicability of the symmetry reduction procedure with an example and numerical simulations.

I. INTRODUCTION

Dimensionality reduction for large scale systems has become an active problem of interest within the automatic control and robotics communities. For instance, in large robotic swarms, guidance and trajectory planning algorithms for coordination while optimizing qualitative features for the swarm of multiple robots are determined by solutions of nonlinear equations which demand a high-computational cost along its integration. A key element in the reduction is a Lie group of symmetries. Lie groups of symmetries appear naturally in many control systems problems [5, 19]. Examples of invariant control problems on Lie groups include motion planning for underwater vehicles [26], conflict resolution in differential games [33], collective motion in biological models [25], and coordination of multi-agent systems [32], [8].

Hybrid systems are dynamical systems with continuous-time and discrete-time components on its dynamics. Simple hybrid systems are a class of hybrid system introduced in [24], denoted as such because of their simple structure. A simple hybrid system is a hybrid system introduced in [24], and extended Poisson reduction in [14] and to time-dependent systems in [10], but to the best of our knowledge, the hybrid analogue for symmetry reduction in mechanical systems subject to external forces has not been explored in the literature. This paper attempts to go one step further and to consider symmetry reduction of simple hybrid Lagrangian system subject to external non-conservative forces via Routh reduction for simple hybrid forced systems. Fundamental to the reduction procedure has been the recent work [28] on reduction of (non-hybrid) forced Lagrangian systems.

The paper is organized as follows. Sec. II presents the necessary background on the geometry of forced mechanical systems and Routh reduction. Sec. III introduces the class of simple hybrid forced Lagrangian and Hamiltonian systems under consideration and the corresponding relation between both formalisms. The reduction scheme is proposed in Section IV. The reduction technique has been illustrated both analytically and numerically in an expository example.

II. ROUTh REDUCTION FOR FORCED SYSTEMS

We start by recalling some basic facts about mechanical systems subject to external forces.

Let \( Q \) be an \( n \)-dimensional differentiable manifold with local coordinates \((q^i)\), \( 1 \leq i \leq n \), the configuration space of a mechanical system. Denote by \( TQ \) its tangent bundle, that is, if \( T_qQ \) denotes the tangent space of \( Q \) at the point \( q \in Q \), then \( TQ := \bigcup_{q \in Q} T_qQ \), with induced local coordinates \((q^i, q^i)\). Since \( T_qQ \) has a vector space structure, we may consider its dual space, \( T^*_qQ \), and define the cotangent bundle as \( T^*Q := \bigcup_{q \in Q} T^*_qQ \), with local coordinates \((q^i, p_i)\).

The dynamics of a mechanical system can be determined by the Euler-Lagrange equations associated with a Lagrangian function \( L : TQ \to \mathbb{R} \) given by \( (q, \dot{q}) \rightarrow K(q, \dot{q}) - V(q) \), where \( K = \frac{1}{2} ||\dot{q}||^2 \) is the kinetic energy and \( V : Q \to \mathbb{R} \) the potential energy. The Lagrangian \( L \) is said to be regular if \( \det \mathcal{M} := \det \left( \frac{\partial^2 L}{\partial \dot{q}^i \partial \dot{q}^j} \right) \neq 0 \) for all \( i, j \) with \( 1 \leq i, j \leq n \).

The equations describing the dynamics of the system are given by the Euler-Lagrange equations \( \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}^i} \right) = \frac{\partial L}{\partial q^i} \), with \( i = 1, \ldots, n \); a system of \( n \) second-order ordinary differential equations. If \( L \) is regular, the Euler-Lagrange equations induce a vector field \( X_L : TQ \to T(TQ) \) describing the dynamics of the system. In the field of bipedal locomotion [2]. The reduced simple hybrid system is called simple hybrid Routhian system [4]. A hybrid scheme for Routh reduction for simple hybrid Lagrangian systems with cyclic variables is found in [4] and [11], inspired to gain a better understanding of bipedal walking models (see also [2] and references therein). Symplectic reduction for hybrid Hamiltonian systems has been introduced in [3] and extended Poisson reduction in [14] and to time-dependent systems in [10], but to the best of our knowledge, the hybrid analogue for symmetry reduction in mechanical systems subject to external forces has not been explored in the literature.
Lagrangian system, given by

\[ X_L(q^i, ˙q^i) = \left( q^i, ˙q^i; ˙q^i, M^{-1} \left( \frac{\partial L}{\partial q^i} - \frac{\partial^2 L}{\partial q^i \partial ˙q^j} ˙q^j \right) \right). \]

In addition, the motion of the system may be influenced by a non-conservative force (conservative forces may be included into the potential energy), which is a smooth map \( F : TQ \to T^*Q \), locally given by \( F = F_i dq^i \) and geometrically represented by a 1-form on \( Q \). At a given position and velocity, the force will act against variations of the position (i.e., virtual displacements). Lagrange-d’Alember principle leads to the so-called forced Euler-Lagrange equations

\[
\frac{d}{dt} \left( \frac{\partial L}{\partial ˙q^i} \right) - \frac{\partial L}{\partial q^i} = F_i(q, ˙q), \quad i = 1, \ldots, n;
\]

a system of \( n \) second-order ordinary differential equations. If \( L \) is regular equations those equations induce a vector field \( X_L^L : TQ \to T(TQ) \) describing the dynamics of the forced Lagrangian system, given by

\[ X_L^L(q^i, ˙q^i) = \left( q^i, ˙q^i, ˙q^i, M^{-1} \left( \frac{\partial L}{\partial q^i} - \frac{\partial^2 L}{\partial q^i \partial ˙q^j} ˙q^j \right) \right). \]

For the Lagrangian \( L : TQ \to \mathbb{R} \), let us denote by \( FL : L \to T^*Q \) the Legendre transformation associated with \( L \); that is, \( FL : TQ \to T^*Q, (q, ˙q) \mapsto (q, p = \partial L/\partial ˙q) \). The map \( FL : TQ \to T^*Q \) relates velocities and momenta. In fact, the Legendre Transformation connects Lagrangian and Hamiltonian formulations of mechanics (see [1]).

We said that the Lagrangian is hyperregular, if \( FL \) is a diffeomorphism between \( TQ \) and \( T^*Q \) (this is always the case for mechanical Lagrangians). If \( L \) is hyperregular, one can work out the velocities \( ˙q = ˙q(q, p) \) in terms of \( (q, p) \) and define the Hamiltonian function (the “total energy”) \( H : T^*Q \to \mathbb{R} \) as \( H(q, p) = p^i \dot{q}^i(q, p) - L(q, \dot{q}) \), where we have used the inverse of the Legendre transformation to express \( \dot{q} = \dot{q}(q, p) \). The evolution vector field corresponding to the Hamiltonian \( H \), denoted by \( X_H \), is defined by \( X_H = \frac{\partial H}{\partial p_i} \partial_\dot{q}^i - \frac{\partial H}{\partial q^i} \partial_{\dot{q}^i} \), and its integral curves are solutions of Hamilton’s equations

\[ \dot{q}^i = \frac{\partial H}{\partial \dot{q}^i}, \quad \dot{p}_i = -\frac{\partial H}{\partial q^i}. \]

If the system is influenced by a nonconservative force, forced Hamilton’s equations are given by

\[ \dot{q}^i = \frac{\partial H}{\partial \dot{q}^i}, \quad \dot{p}_i = F^H - \frac{\partial H}{\partial q^i}, \]

where \( F^H = FL(F) \).

There exists a large class of systems for which the Lagrangian (resp. Hamiltonian) does not depend on some of the generalized coordinates. Such coordinates are called cyclic or ignorable, and the corresponding generalized momenta are easily checked to be constants of motion - see [1], [18]. Routh’s reduction procedure is a classical reduction technique which takes advantage of the conservation laws to define a reduced Lagrangian function, so-called Routhian function, such that the solutions of the Euler-Lagrange equations for the Routhian are in correspondence with the solutions of Euler-Lagrange equations for the original Lagrangian, when the conservation of momenta is taken into account.

Routh’s reduction can be extended to forced systems as follows [18]: the starting point for Routhian reduction for forced Lagrangian systems is a configuration space of the form \( Q = Q_1 \times Q_2 \), where we denote an element \( q^j \in Q_1 \) by \( q^j = (q^1, q^j) \) with \( q^1 \in Q_1 \) and \( q^j \in Q_2 \), with \( j = 2, \ldots, n \).

Let \( L(q^1, ˙q^1, q^j, ˙q^j) \) be a hyper-regular Lagrangian with cyclic coordinate \( q^1 \), that is, \( \partial L/\partial ˙q^1 = 0 \) and let \( F_i \) be a force of the non-conservative form such that \( F_i \) is independent of \( q^1 \) for all \( i = 1, \ldots, n \) and \( F_i(q^2, \ldots, q^n) = 0 \). Fundamental to reduction is the notion of a momentum map \( J_L : TQ \to \mathfrak{g}^* \), which makes explicit the conserved quantities in the system, with \( \mathfrak{g} \) the Lie algebra associated with the Lie group of symmetries and \( \mathfrak{g}^* \) denoting its dual as vector space. In the framework we are considering here, \( J_L(q^1, ˙q^1, q^j, ˙q^j) = \frac{\partial L}{\partial ˙q^1} \). Fix a value of the momentum \( \mu = \frac{\partial L}{\partial ˙q^1} \). Since \( L \) is hyper-regular, the last equation admits an inverse, and allows us to write \( ˙q^1 = f(q^2, \ldots, q^n, ˙q^2, \ldots, ˙q^n, \mu) \). Consider the function \( R^0(q^j, ˙q^j) = (L - q^1 \mu)_\mu \), where the notation \( \mu \) means that we have used the relation \( \mu = \frac{\partial L}{\partial ˙q^1} \) to replace all the appearances of \( ˙q^1 \) in terms of \( (q^j, ˙q^j) \) and the parameter \( \mu \). \( R^0 \) is called Routhian function.

If we regard \( R^0 \) and \( F_i \) as a new Lagrangian and external force in the variables \( (q^j, ˙q^j) \), then the solutions of the forced Euler-Lagrange equations for \( R^0 \) with \( F_i \) are in correspondence with those of \( L \) with \( F_i = \mu \partial L/\partial ˙q^1 \).

(a) Any solution of the forced Euler-Lagrange equation for \( L \) and \( F \) with momentum \( \mu = \frac{\partial L}{\partial ˙q^1} \) projects onto a solution of the forced Euler-Lagrange equations for \( R^0 \) and \( F_i \), \( \mu \frac{\partial L}{\partial ˙q^1} \). These equations will be referred to as forced Routh equations and they induce a vector field \( X^L_R : TQ_2 \to T(TQ_2) \) describing the dynamics of the reduced system, called Routhian vector field.

(b) Conversely, any solution of forced Routh equations for \( R^0 \) and \( F_i \) can be lifted to a solution of the forced Euler-Lagrange equations for \( L \) with \( F \) and \( \mu = \frac{\partial L}{\partial ˙q^1} \).

Example 2.1 (Billiard with dissipation): Consider a particle of mass \( m \) in the plane which is free to move inside the surface defined by \( x^2 + y^2 = 1 \). The surface of the “billiard” is assumed to be rough in such a way that the friction is non-linear on the velocities.

The Lagrangian \( L : T\mathbb{R}^2 \to \mathbb{R} \) is given by

\[ L(x, y, \dot{x}, \dot{y}) = \frac{1}{2} m (\dot{x}^2 + \dot{y}^2) \]

and \( F(x, y, \dot{x}, \dot{y}) = F_1 dx + F_y dy \) is an external force given by \( F_x = 2 c (\dot{x} y - \dot{y} x) \), \( F_y = -2 c (\dot{x} y - \dot{y} x) \), for a constant \( c > 0 \). The equations of motion for the particle off the boundary are then

\[ m \ddot{x} = -2 c (\dot{y} x - \dot{x} y), \quad m \ddot{y} = 2 c (\dot{x} y - \dot{y} x) \]

By introducing polar coordinates \( L \) and \( F \) become

\[ L(\theta, r, \dot{\theta}, \dot{r}) = \frac{m}{2} (\dot{r}^2 + r^2 \dot{\theta}^2), \]

and \( F(\theta, r, \dot{\theta}, \dot{r}) = -2 c r^3 \dot{r} \) if \( L \) is hyper-regular and both \( L \) and \( F \) are independent of \( \theta \). The forced Euler-Lagrange equations (in polar coordinates) are \( \ddot{r} = -\frac{2 c m}{r^3} r^2 \dot{\theta}^2 \). Note that the momentum map \( J_L \) for \( \theta \) is preserved, that is, by considering \( \mu = m \dot{r} \dot{\theta} \) (i.e., \( \dot{\theta} = \frac{m \dot{r}}{m \dot{r}} \)) the Routhian and the reduced force takes the form \( R^0(\theta, \dot{r}) = 2 \frac{\dot{r}^2}{m \dot{r}} - \frac{2 c m}{m \dot{r}} \), \( F_\mu = -2 c m \frac{\dot{r}}{m \dot{r}} \) and the forced reduced Euler-Lagrange equations for the Routhian \( R^0 \) are given by \( \ddot{r} = \frac{2 \dot{r}^2}{m \dot{r}} - 2 c m \frac{\dot{r}}{m \dot{r}} \).

III. Simple Hybrid Forced Lagrangian Systems

Roughly speaking, the term hybrid system refers to a dynamical system which exhibits both a continuous and a discrete time behaviors. In the literature, one finds slightly different definitions of hybrid system depending on the specific class of applications of interest. For simplicity, and following [24], [4], we will restrict
ourselves to the so-called simple hybrid mechanical systems in Lagrangian form.

Simple hybrid systems [24] (see also [34]) are characterized by the 4-tuple \( \mathcal{L} = (D, X, S, \Delta) \) where \( D \) is a smooth manifold, the domain, \( X \) is a smooth vector field on \( D \), \( S \) is an embedded submanifold of \( D \) with co-dimension 1 called switching surface, and \( \Delta : S \to D \) is a smooth embedding called the impact map. \( S \) and \( \Delta \) are also referred as the guard and reset map, respectively. The dynamics associated with a simple hybrid system is described by an autonomous system with impulse effects as in [34]. We denote by \( \Sigma_{\mathcal{L}} \) the simple hybrid dynamical system generated by \( \mathcal{L} \), that is,

\[
\Sigma_{\mathcal{L}} : \begin{cases} 
\dot{\gamma}(t) = X(\gamma(t)), & \text{if } \gamma^{-}(t) \notin S, \\
\gamma^{+}(t) = \Delta(\gamma^{-}(t)) & \text{if } \gamma^{-}(t) \in S,
\end{cases}
\]

(1)

where \( \gamma : I \subset \mathbb{R} \to D \), and \( \gamma^{-}, \gamma^{+} \) denote the states immediately before and after the times when integral curves of \( X \) intersects \( S \) (i.e., pre and post impact of the solution \( \gamma(t) \) with \( S \)), where \( \gamma^{-}(t) := \lim_{\tau \to t^{-}} x(\tau), \gamma^{-}(t) := \lim_{\tau \to t^{+}} x(\tau) \) are the left and right limits of the state trajectory \( \gamma(t) \).

A solution of a hybrid system may experience a Zeno state if infinity many impacts occur in a finite amount of time. It is particularly problematic in applications where numerical work is used, as computation time grows infinitely large at these Zeno points. There are two primary modes through which Zeno behavior can occur: (i) A trajectory is reset back onto the guard, prompting additional resets. To exclude this behavior, we require that \( S \cap \overline{\mathbb{S}}(S) = \emptyset \), where \( \overline{\mathbb{S}}(S) \) denotes the closure as a set of \( \Delta(S) \). This ensures that the trajectory will always be reset to a point with positive distance from the guard. (ii) The set of times where a solution to our system reaches the guard (and is correspondingly reset) has a limit point. This happens, for example, in the case of the bouncing ball with coefficient of restitution 1/2 - see [6]. To exclude these types of situations, we require the set of impact times to be closed and discrete, as in [34], so, we will assume implicitly throughout the remainder of the paper that \( \overline{\mathbb{S}}(S) \cap S = \emptyset \) and the set of impact times is closed and discrete.

Given a smooth (constraint) function \( h : Q \to \mathbb{R} \) on a configuration space \( Q \) such that \( h^{-1}(0) \) is a smooth submanifold, we can construct a domain and a guard explicitly - see [6], [4].

For this constraint function we have an associated domain, \( D \), defined to be the manifold (with boundary) \( D = \{(q, \dot{q}) \in TQ : h(q) \geq 0\} \). Similarly, we have an associated guard, \( S \), defined as the submanifold of \( D \) as \( S = \{(q, \dot{q}) \in TQ : h(q) = 0, \; dh_{q} \dot{q} \geq 0\} \), where \( dh_{q} = \frac{\partial h}{\partial q} \).

In a simple hybrid Lagrangian system the impact can be obtained from the Newtonian impact equation (see [6] for instance) \( p : TQ \to TQ \) given by

\[
P(q, \dot{q}) = \dot{q} - (1 + c) \frac{dh_{q} \dot{q}}{dh_{q} M(q)^{-1} dh_{q} M(q)^{-1} dh_{q} T} M(q)^{-1} dh_{q} T
\]

where \( M(q) \) is the inertial matrix for the Lagrangian system.

**Definition 3.1:** A simple hybrid forced Lagrangian system \( \mathcal{L}^F = (D, X, S, \Delta) \) is said to be a simple hybrid forced Lagrangian system if it is determined by \( \mathcal{L}^F := (TQ, X^F, S, \Delta) \), where \( X^F : TQ \to T(TQ) \) is the forced Lagrangian vector field, \( S \) the switching surface and \( \Delta : S \to TQ \) the impact map.

**Definition 3.2:** The simple hybrid forced dynamical system generated by \( \mathcal{L}^F \) is given by

\[
\Sigma_{\mathcal{L}^F} : \begin{cases} 
\dot{\gamma}(t) = X^F(\gamma(t)), & \text{if } \gamma^{-}(t) \notin S, \\
\gamma^{+}(t) = \Delta(\gamma^{-}(t)) & \text{if } \gamma^{-}(t) \in S,
\end{cases}
\]

(2)

where \( \gamma(t) = (q^a(t), \dot{q}^a(t)) \in TQ \).

**Definition 3.3:** A hybrid flow for \( \mathcal{L}^F \) is a tuple \( \chi^F = (\Lambda, J, \epsilon) \), where

- \( \Lambda = \{0, 1, 2, \ldots\} \subset \mathbb{N} \) is a finite (or infinite) indexing set,
- \( J = \{I_i\}_{i \in \Lambda} \) a set of intervals, called hybrid intervals where \( I_i = [\tau_i, \tau_{i+1}] \) if \( i, i + 1 \in \Lambda \) and \( J_{N-1} = [\tau_{N-1}, \tau_N] \) or \( [\tau_{N-1}, \infty) \) if \( |\Lambda| = N, N \in \mathbb{N} \).

The relation between both hybrid flows is given by the following result, based on the well-known equivalence between the Lagrangian and Hamiltonian dynamics in the hyperregular case achieved via \( \mathcal{F} \).

**Proposition 3.1:** If \( \chi^F = (\Lambda, J, \epsilon) \) is a hybrid flow for \( \mathcal{L}^F, S_H = \mathcal{F}(L(S)) \), and \( \Delta_H \) is defined in such a way that \( \mathcal{F}(L) \circ \Delta = \Delta_H \circ \mathcal{F}(L) \), then \( \chi^F = (\Lambda, J, \epsilon) \) with \( \mathcal{F}(L)(\psi) = \mathcal{F}(L) \).

Proof: If \( \epsilon_i(t) \) is an integral curve of \( X^H, \epsilon_i(t) = (\mathcal{F}(L) \circ \epsilon_i(t)) \) is an integral curve for \( X^H \). In this way, if we consider a solution \( \epsilon_i(t) \) with initial value \( \epsilon_i(0) \in \mathcal{F}(L) \), \( \epsilon_i(0) \subset [\tau_i, \tau_{i+1}] \), then \( \epsilon_i(t) \) is a solution with initial value \( \epsilon_i(0) \in \mathcal{F}(L) \), \( \epsilon_i(0) \subset [\tau_i, \tau_{i+1}] \). Likewise for a solution \( \epsilon_i(t) \) defined on \( [\tau_i, \tau_{i+1}] \), we get a corresponding solution \( \epsilon_i(t) \) defined on the same hybrid interval \( [\tau_i, \tau_{i+1}] \). Proceeding inductively, one finds \( \epsilon_i(t) \) defined on \( [\tau_i, \tau_{i+1}] \). It only remains to check that \( \epsilon_i(t) \) satisfies \( \epsilon_i(\tau_{i+1}) = \epsilon_i(\tau_{i+1}) \), but using the properties of \( \mathcal{F}(L) \),

\[
(i) \; \epsilon_i(\tau_{i+1}) = (\mathcal{F}(L) \circ \epsilon_i(t)) \subset \mathcal{F}(L) \\
(ii) \; \Delta_H(\epsilon_i(\tau_{i+1})) = \mathcal{F}(L) \circ \Delta(\epsilon_i(\tau_{i+1})) = \mathcal{F}(L) \circ \epsilon_i(\tau_{i+1}) = \epsilon_i(\tau_{i+1}).
\]

Therefore, the 4-tuple \( \mathcal{L}^F = (TQ, X^F, S, \Delta) \), is a simple hybrid forced Lagrangian system with \( Q = \mathbb{R}^2 \), and \( L \) and \( F \) as described in Example 2.

**IV. ROUH REDUCTION OF SIMPLE HYBRID FORCED LAGRANGIAN SYSTEMS**

Let \( \mathcal{L}^F = (TQ, X^F, S, \Delta) \) be a simple hybrid forced Lagrangian system. The starting point for symmetry reduction is a Lie group action \( \psi : G \times Q \to Q \) of some Lie group \( G \) on the manifold \( Q \). We will assume that all the actions satisfy some regularity conditions as to do reduction, for instance, one can consider free and proper actions [1].

There is a natural lift \( \underline{\psi}^T \) of the action \( \psi \) to \( T^*Q \), the cotangent lift, defined by \( (g, \langle q, \dot{q} \rangle) \mapsto (T^*\psi_{g^{-1}}(q, \dot{q})) \). It enjoys the following properties [1], [27]:

...
• \( \psi^{T^*Q} \) is a symplectic action, meaning that \( (\psi_g^{T^*Q})*\Omega = \Omega \), with \( g \) being the canonical symplectic 2-form on \( T^*Q \), \( \Omega = dq \wedge dp \).

• It admits an Ad*-equivariant momentum map \( J : T^*Q \to g^* \) given by \( J(g(q),p) = (p,\xi_g) \), \( \forall \xi \in g \), where \( \xi_g(q) = d(\psi_{\exp}(\xi_g))/dt \) is the infinitesimal generator of \( \xi \in g \), with \( g \) the Lie algebra of \( G \).

Likewise, \( \psi^Q \) denotes the tangent lift action on \( TQ \), defined by \( \psi\circ\pi \). To perform a hybrid reduction one needs to impose some compatibility conditions between the action and the hybrid system (see [4] and [3]). By an hybrid action on the simple hybrid forced Lagrangian system \( Z_F \) we mean a Lie group action \( G \times Q \to Q \) such that

• \( L \) is invariant under \( \psi^Q \), i.e. \( L \circ \psi^Q = L \).

• \( \psi^Q \) restricts to an action of \( G \) on \( S \).

• \( \Delta \) is equivariant with respect to the previous action, namely \( \Delta \circ \psi^Q|_S = \psi^Q \circ \Delta \).

Recall that \( \psi^Q \) admits an Ad*-equivariant momentum map \( J_L : TQ \to g^* \) given by \( J_L = J \circ Fl \). This follows directly from the invariance of \( L \), since it implies that \( FL \) is an equivariant diffeomorphism, i.e. \( FL \circ \psi^Q = \psi_g \circ FL \).

The hybrid equivalent of momentum map is the notion of hybrid momentum map introduced in [4]. \( J_L \) is an hybrid momentum map if the diagram

\[
\begin{array}{ccc}
TQ & \xrightarrow{\iota} & S \\
\downarrow J_L & & \downarrow \Delta \\
TQ & \xrightarrow{\iota_1} & TQ
\end{array}
\]

commutes, where \( i \) is the canonical inclusion from \( S \) to \( TQ \).

We remind that (see [27] for instance) by denoting \( \{ \phi^x_t \} \) the flow of a vector field \( X \) on \( Q \), we can also define the complete lift \( X^c \) of \( X \) in terms of its flow. We say that \( X^c \) is the vector field on \( TQ \) with flow \( \{ T_\theta \phi^X \} \). In other words, \( X^c(v_q) = \sum_{\mu=0}^\infty (T^\mu_\theta \phi^X)^{(v_q)} \), or in local coordinates, \( X^c = X + \sum_{\mu=0}^\infty \frac{\partial}{\partial \theta^\mu} \frac{\partial}{\partial \theta^\mu} \).

For the Lagrangian side, one needs a further regularity condition, sometimes referred to as \( G \)-regularity. Precisely, one has the following definition [30] (for an alternative, equivalent definition, see [29]). Let \( L \) be an invariant Lagrangian on \( TQ \) and denote by \( \xi_Q \) the infinitesimal generator for the associated action. We say that \( L \) is \( G \)-regular if, for each \( v_q \in TQ \), the map \( J^c_\xi : g \to g^* \), \( \xi \mapsto J_L(v_q + \xi_Q(q)) \), \( v_q \in TQ, q \), is a diffeomorphism. In a nutshell, \( G \)-regularity amounts to regularity "with respect to the group action". From now on we will assume that the Lagrangian is \( G \)-regular. In fact, this is always the case for mechanical Lagrangians.

Consider a simple hybrid forced Lagrangian system \( Z_F = (TQ, X^c_F, S, \Delta) \) equipped with an hybrid action \( \psi \) and \( L \) invariant under \( \psi^Q \). We can apply a hybrid analog of the symplectic reduction Theorem for forced Lagrangian systems [28] to the simple hybrid forced Lagrangian system \( Z_F = (TQ, X^c_F, S, \Delta) \) as follows: Consider the momentum map \( J_L : TQ \to g^* \), given by \( J_L(v_q)(\xi) = \alpha_L(v_q)(\xi_Q(v_q)) \), where \( \alpha_L = \pi_0 \circ dL \) being \( S \) the vertical endomorphism on \( TQ \) (see [27]) locally given by \( S = dq \otimes \frac{\partial}{\partial \theta^\mu} \) and denote by \( \omega_L = -d\alpha_L \), the Poincaré-Cartan 2-form [27], where the symbol \( \otimes \) denotes a tensorial product. In [27] (see [25]), it is shown that \( \omega_L \) is the equivariance of the momentum map \( J_L \).

For each \( \xi \in g \) and \( v_q \in TQ \), consider the function \( J^c_L : TQ \to \mathbb{R} \) given by \( J^c_L(v_q)(\xi) = \langle J_L(v_q), \xi \rangle \). Let \( \xi \in g \), then \( J^c_L \) is a conserved quantity for \( X^c_F \) if and only if \( F(\xi^c_Q) = 0 \) (see [28]), where \( \xi^c_Q \) denotes the complete lift of the vector field \( \xi_Q \) given by the infinitesimal generator for the Lie group action \( \psi \). In addition, the vector subspace of \( g \) given by \( g_F = \{ \xi \in g : F(\xi^c_Q) = 0, \xi^c_Q \circ dF = 0 \} \) is a Lie subalgebra of \( g \) (see [28]). In particular, for each \( \xi \in g_F, \xi^c_Q \) is a symmetry of the forced Lagrangian system given by \( L \) and \( F \).

Let \( G_F \subset G \) be the Lie subgroup generated by \( g_F \) and \( J_F : TQ \to g_F^* \) the reduced hybrid momentum map. Let \( \mu \in g_F^* \) be a hybrid regular value of \( J_F \), which means that \( \mu \) is a regular value of both \( J_F \) and \( J_F|_S \) and let \( \{ G_F \mu \} \) be the isotropy subgroup in \( \mu \). Note that, since \( L \) is invariant under \( \psi^Q \) and \( G \)-regular, then:

(i) The reduced space \( M_\mu := J^{-1}_F(\mu)/(G_F)_\mu \) is a symplectic manifold, with symplectic structure \( \omega_\mu \), uniquely determined by \( \pi_0^*\omega_\mu = \nu_\mu^* \omega_L \), where \( \pi_0 : J^{-1}_F(\mu) \to M_\mu \) and \( \nu_\mu : J^{-1}_F(\mu) \to TQ \) denotes the canonical projection and the canonical inclusion, respectively. Moreover, \( J^{-1}_F(\mu) \) is a submanifold of \( TQ \) and \( X^c_F \) is tangent to it.

(ii) \( L \) induces a function \( R^\mu : M_\mu \to \mathbb{R} \) defined by \( R^\mu \circ \pi_0 = \mu \).

(iii) \( J_F|_S(\mu) \subset S \) is \( (G_F)_\mu \)-invariant and hence reduces to a submanifold of the reduced space which we denote \( S_\mu \subset J^{-1}_F(\mu)/(G_F)_\mu \).

(iv) Again, using invariance, \( \Delta \) reduces to a map \( \Delta_\mu : S_\mu \to J^{-1}_F(\mu)/(G_F)_\mu \).

(v) \( F \) induces a reduced 1-form \( F_\mu \) on \( M_\mu \), uniquely determined by \( \pi_0^*F_\mu = \nu_\mu^*F \).

A case of special interest with regards to applications is when \( Q = S^1 \times M \), where \( M \) is called the shape space and the action is simply \( (\theta,x) \mapsto (\theta + \alpha, x) \). This is often the situation when dealing with simple models of bipedal walkers, see e.g. [2]. From now on, we will assume we work in this setting. While this is indeed a strong assumption, it is always the case locally, so long as it applies to the domain of interest of an specific problem the procedure applies.

The forced Lagrangian system has a cyclic coordinate \( \theta \), i.e., \( L \) is a function of the form \( L(\theta,x,\dot{x}) \), and the forced \( F \) is such that \( F_\theta = 0 \) and \( F_\theta \) independent of \( \theta \) with \( F = F_\theta d\theta + F_\theta dx \). The conservation of the momentum map \( J_F = \mu \) reads \( \frac{\partial \mu}{\partial \theta} = 0 \), and one can use this relation to express \( \theta \) as a function of the remaining -non cyclic- coordinates and their velocities, and the prescribed regular value of the momentum map \( \mu \). We point out that it is at this stage that \( G \)-regularity of \( L \) is used: it guarantees that \( \theta \) can be worked out in terms of \( x, \dot{x} \) and \( \mu \). If one chooses the canonical flat connection on \( Q \to Q/S^1 = M \), then the Routhian can be computed as

\[
R^\mu(x,\dot{x}) = \left[ L(\theta,x,\dot{x}) - \mu \theta \right]_{\theta = \theta(x,\dot{x},\mu)},
\]

where the notation means that we have everywhere expressed \( \theta \) as a function of \( (x,\dot{x},\mu) \). Note that [6] is the classical definition of the Routhian [31]. Let us first consider the case in which the momentum map is preserved in the collisions with the switching surface (elastic case). We then have:

**Proposition 4.1:** In the situation above:

(a) Any solution of \( Z_F = (TQ, X^c_F, S, \Delta) \) with momentum \( \mu \) projects onto a solution of \( Z^\mu_F = (T(Q/S^1), X^\mu_F, S_\mu, \Delta_\mu) \).

(b) Any solution of \( Z^\mu_F = (T(Q/S^1), X^\mu_F, S_\mu, \Delta_\mu) \) is the projection of a solution of \( Z_F = (TQ, X^c_F, S, \Delta) \) with momentum \( \mu \).
Collisions with the switching surface will, in general, modify the value of the momentum map (nonelastic case). Therefore, if $\mathcal{J} = \{I_j\}_{j \in \Delta}$ is the hybrid interval, the Routhian has to be defined in each $I_j$ taking into account the value of the momentum $\mu_i$ after the collision at time $\tau_j$. Note that this also has influence in the way the reset map $\Delta$ is reduced. This will be clarified in the examples below.

Let us denote: (1) $\mu_i$, the momentum of the system in $I_j = [\tau_i, \tau_{i+1}]$, (2) $\Delta_{\mu_i}$, the reduction of $\Delta$, and (3) $S_{\mu_i}$, the reduction of $S$, so there is a sequence of reduced simple hybrid Routhian systems. The fact that the momentum will, in general, change with time, we have $\tau = \int_0^t \mu_i(x, y, \dot{x}, \dot{y}, \cdots) \, dt$, where we have replaced the expression for $\mu_i$.

If one wishes, as usual, to use a reduced solution to reconstruct the systems. The fact that the momentum will, in general, change with time, we have $\tau = \int_0^t \mu_i(x, y, \dot{x}, \dot{y}, \cdots) \, dt$, where we have replaced the expression for $\mu_i$.

Example 4.1: Continuing with Examples 2.1 and 3.4 if we square both sides of (4), and noting that
\[
2\ddot{x} + 2y\dot{y} = \frac{d}{dt}(x^2 + y^2) = \frac{d}{dt}(\dot{r}^2) = 2\dot{r}^2,
\]
we have $(\dot{r}^+)^2 = (\dot{r}^-)^2 + (2\dot{r}^-\dot{r}^+)x^2 - 4x\dot{x}^-\dot{r}^- - 4x\dot{r}^-$, and symmetrically to $\dot{y}^-$. Add $(\dot{r}^+)^2 + (\dot{y}^+)^2$. We can conclude
\[
(\dot{r}^+)^2 = (\dot{r}^-)^2 + (2\dot{r}^-\dot{r}^+)(x^2 + y^2) - 4(x\dot{x}^- + y\dot{y}^-)\dot{r}^- = (\dot{r}^-)^2 + 4\dot{r}^2(\dot{r}^2 - 1).
\]
This means that, since the collision occurs at $r = 1$, we have $(\dot{r}^+)^2 = (\dot{r}^-)^2$, then the solution that is obtained (physically) is $\dot{r}^+ = -\dot{r}^-$. For $\theta = \arctan(y/x)$, we have
\[
\dot{\theta} = \frac{1}{1 + (y/x)^2} \left( \frac{\dot{y}^+ x - y \dot{x}^+}{x^2} \right) = \frac{1}{r^2} \left( \dot{y}^- x - y \dot{x}^- \right) = \dot{\theta}^-.
\]
where we have replaced the expression for $\dot{x}^+, \dot{y}^+$ and we used that $x^2 + y^2 = r^2$ and $(y\dot{x}^- - \dot{y}^- x) = -r^2\dot{\theta}^-$. It is understood that the “minus” square root is taken in $\dot{r}^+$ (the particle bounces on the boundary after the collision). The assumption of elastic collision implies, in particular, that the momentum map is preserved. This is clear since $r$ and $\theta$ do not change with the collision. The Routhian, the reduced force and the reduced forced Euler-Lagrange equations are given in Example 2.1. The reduced reset map is determined by the expression for $\dot{r}^+$ (note that the expression drops to the quotient since it only involves $r$ and $\dot{r}$). The reduced switching surface is $S_{\mu_i} = \{x^2 = 1, \dot{r} > 0\}$. One obtains the simple hybrid forced Routhian system $\mathcal{L} = (TQ_{\text{red}}, \Omega^a, S_{\mu_i}, \Delta_{\mu_i})$, with $Q_{\text{red}} \simeq \mathbb{R}^+$ parametrized by the radial coordinate $r$.

Figures 1 and 2 show numerical results using Python for two different values of the dissipation parameter $c$. The remaining parameters are the same for both simulations: $m = 1, r(0) = 0.5, \dot{r}(0) = 2, \theta(0) = 0$ (rad) and $\dot{\theta}(0) = 1$ (rad/s). The reduced dynamics is solved numerically (dashed purple line) and used to integrate (numerically) the reconstruction equation $\dot{\theta} = \frac{\mu}{mr^2}$, with $\mu$ determined from the initial conditions. Switching surfaces $S$ and $S_{\mu_i}$ are represented with green solid lines. Note also that the impact times on which the particle bounces are also obtained numerically.

V. ACKNOWLEDGMENT

This work was supported by Ministerio de Ciencia e Innovación (Spain) under grant PID2019-106715GB-C21. The authors also acknowledge Manuela Gamonal for the help provided with the numerical simulations.
