Figure S1. Principal component analysis of the total kākāpō dataset (n=161) using filtered SNP markers (n=12,241). Grey points represent Stewart Island founders and descendants, and green points for mainland descendants. Green star represents sole mainland founder, Richard-Henry.
Figure S2. Fin-plot for KGD-filtered SNPs (n=11,782) for the total kākāpō dataset (n=161) (Dodds et al. 2015). (a) Hardy-Weinberg disequilibrium plotted against minor allele frequency (MAF), with points shaded grey (low SNP depth) to blue (high SNP depth). (b) G₃ self-relatedness estimates (diagonal elements of genomic relatedness matrix) plotted against log-transformed sample depth.
Figure S3. Density plot representing observed homozygosity for the total kākāpō dataset (n=161) using filtered SNP markers (n=12,241). Dashed line represents the mean, with blue shading for Stewart Island and red for mainland descendants.
Figure S4 Molecular tests of identity disequilibrium for the total kākāpō dataset (n=161) using filtered SNP markers (n=12,241). (a) Distribution of the $g^2$ statistic ($p = 0.01$). (b) Corresponding distribution of heterozygosity-heterozygosity correlation coefficients. For both plots, the dashed bar represents the mean and error bars are the 95% confidence interval produced after bootstrapping (n=1000).
Figure S5. Correlations between inbreeding estimates for dataset containing only Stewart Island descendants (n=151): (a) $F_H$ and $F_{RoH}$, (b) $F_H$ and $F_{GRM}$, and (c) $F_{RoH}$ and $F_{GRM}$. Pearson’s R and P-values are above each plot.
Figure S6. Density plots for (a) $F_H$, (b) $F_{GRM}$, (c) $F_{RoH}$ for the total kākāpō dataset (n=161). Dashed line represents the mean.
Figure S7. Density plots for (a) $F_H$, (b) $F_{GRM}$, (c) $F_{RoH}$, and (d) $F_{RoH10}$ for all individuals partitioned by Stewart Island or mainland descendant group. Dashed lines represent the mean for each group, with blue shading for Stewart Island and red for mainland descendants.
**Figure S8.** Genomic architecture of runs of homozygity (RoH) for the total kākāpō dataset (n=161) using filtered SNP markers (n=12,241). (a) Total number of RoH for all individuals on each chromosome. Density plots for: (b) number of RoH per individual, (c) total length of RoH between all individuals. Dashed lines represent the mean for each group, with blue shading for Stewart Island and red for mainland descendants.
Table S1. Summary of generalized linear model (GLM) with a binomial distribution and logit link function. Fixed predictor variables of ancestry and inbreeding (F\textsubscript{RoH}), and response variable of chick survivorship (survival ~ ancestry + F\textsubscript{RoH}).

| Variable | Estimate | SE  | z-value | p-value | 95% Confidence interval |
|----------|----------|-----|---------|---------|-------------------------|
| Intercept| -0.751   | 2.276 | -0.330  | 0.741   | -5.372, 3.759           |
| Ancestry | -0.442   | 1.634 | -0.270  | 0.787   | -3.751, 2.826           |
| F\textsubscript{RoH} | 0.502 | 18.291 | 0.027  | 0.978 | -36.394, 37.065 |
