On the Hilbert scheme of smooth curves in \( \mathbb{P}^4 \) of degree \( d = g + 1 \) and genus \( g \) with negative Brill-Noether number

Changho Keem and Yun-Hwan Kim

Abstract. We denote by \( \mathcal{H}_{d,g,r} \) the Hilbert scheme of smooth curves, which is the union of components whose general point corresponds to a smooth irreducible and non-degenerate curve of degree \( d \) and genus \( g \) in \( \mathbb{P}^r \). In this article, we show that for low genus \( g \) outside the Brill-Noether range, the Hilbert scheme \( \mathcal{H}_{g+1,g,4} \) is non-empty whenever \( g \geq 9 \) and irreducible whose only component generically consists of linearly normal curves unless \( g = 9 \) or \( g = 12 \). This complements the validity of the original assertion of Severi regarding the irreducibility of \( \mathcal{H}_{d,g,r} \) outside the Brill-Noether range for \( d = g + 1 \) and \( r = 4 \).

Keywords. Hilbert scheme, algebraic curves, linear series.

1. An overview, preliminaries and basic set-up

Given non-negative integers \( d, g \) and \( r \geq 3 \), let \( \mathcal{H}_{d,g,r} \) be the Hilbert scheme of smooth curves parametrizing smooth irreducible and non-degenerate curves of degree \( d \) and genus \( g \) in \( \mathbb{P}^r \).

It seems that the irreducibility of \( \mathcal{H}_{d,g,r} \) was first announced by Severi in the papers [22] & [23]. Severi asserts with an incomplete proof that \( \mathcal{H}_{d,g,r} \) is irreducible for \( d \geq g + r \) and more generally, \( \mathcal{H}_{d,g,r} \) is irreducible in the Brill-Noether range

\[
\rho(d, g, r) := g - (r + 1)(g - d + r) \geq 0.
\]

This paper has started and prepared for publication when the first named author was enjoying the hospitality and the stimulating atmosphere of the Max-Planck-Institut für Mathematik (Bonn). Also supported in part by National Research Foundation of South Korea (Grant # 2019R1I1A1A01058457).
After Severi, the irreducibility of $H_{d,g,r}$ has been studied by several authors. Ein proved irreducibility of $H_{d,g,r}$ in the range $d \geq g + r$ for $r = 3$ and $r = 4$; cf. [7, Theorem 4] and [8, Theorem 7].

For families of curves in $\mathbb{P}^3$ of lower degree $d \leq g + 2$, the most updated result is that any non-empty $H_{d,g,3}$ is irreducible for every $d \geq g$; cf. [15, Theorem 1.5], [16, Proposition 2.1 and Proposition 3.2], [13, Theorem 3.1] and [18]. Note that even in the range $d \geq g$ and $r = 3$, the Brill-Noether number may well become negative, however there is no reducible $H_{d,g,3}$ in this range. The reducible examples of $H_{d,g,3}$ occur only when $d \leq g - 1$, e.g. $H_{8,9,3}$ or $H_{9,10,3}$ both of which have two components. In every such known reducible example of $H_{d,g,3}$ when $d \leq g - 1$, the Brill-Noether numbers is negative.

For families of curves in $\mathbb{P}^4$ of lower degree $d \leq g + 3$ beyond the range $d \geq g + 4$, there has been some extensions of the result of Ein. Hristo Iliev proved the irreducibility of $H_{d,g,4}$ for $d = g + 3$, $g \geq 5$ and $d = g + 2$, $g \geq 11$; cf. [13]. Note that the genus restriction on the genus $g$ in these results is equivalent to the condition $\rho(g + 3,g,4) > 0$ or $\rho(g + 2,g,4) > 0$. The non-negativity (or positivity) of the Brill-Noether number indeed assures the existence of a distinguished unique component of the Hilbert scheme dominating the moduli space $M_g$ and sometimes this makes the problem rather easier to handle. However, outside the Brill-Noether range, i.e. in the range $\rho(d,g,r) < 0$, the problem usually becomes more subtle and one needs somewhat thorough knowledge or case by case analysis of the classes of projective curves under consideration.

For a fixed value $d$ near to the genus $g$ and small $r$, the genus becomes rather small if the Brill-Noether number is negative. Indeed methods of the proof of the irreducibility of $H_{g+2,g,4}$ for low genus cases - which is an extension of the result of H. Iliev regarding the irreducibility of $H_{g+2,g,4}$ - significantly differ from those in the Brill-Noether range; cf. [19, Corollary 2.2].

On the other hand, there are several examples violating the original Severi’s assertion due to many authors; cf. [8, Proposition 9], [14], or [6]. Despite all these denumerably many counterexamples to the Severi’s assertion, it is worthwhile to stress that all the reducible counterexamples (in the Brill-Noether range) are those such that all the extra components consist of non linearly normal curves. In this regard, we denote by $H_{d,g,r}^L$ the union of those components of $H_{d,g,r}$ whose general element is linearly normal. For a detailed explanation and sources in the literature regarding the Hilbert scheme of linear normal curves $H_{d,g,r}^L$, the reader are advised to refer [5] or [17, Remark 1.1] and references therein.

In this article, we show that $H_{g+1,g,4}$ is non-empty for $g \geq 9$ and irreducible except for $g = 9$ and $g = 12$ outside the the Brill-Noether range; i.e. $g \leq 14$. 

The following remarks would help the readers to get down to the main issues of the Hilbert scheme business of this kind.

**Remark 1.1.** (1) It has been shown in [17] that any non-empty $H_{g+1,g,4}^L$ is irreducible for $g \neq 9$, inside or outside the Brill-Noether range. Note that a non-empty $H_{d,g,4}^L$ is known to be irreducible only in the range $d \geq g + 2$ by those results due to Ein, H. Iliev and the authors which were already mentioned.

(2) However, at least to the knowledge of the authors, the irreducibility of $H_{g+1,g,4}^L$ has not been fully settled yet. In [17] the irreducibility of $H_{g+1,g,4}^L$ was shown by the irreducibility of the Severi variety and the fact that the family of complete linear systems on moving curves corresponding to $H_{g+1,g,4}^L$ has the expected dimension, which is not directly applicable to other possible components consisting of non-linearly normal curves.

(3) In this paper the author would like to make an attempt for a settlement of the irreducibility of $H_{g+1,g,4}^L$ outside the Brill-Noether range, and hopefully the methods we employ in this article may shed light on handling the cases inside the Brill-Noether range as well.

The organization of this paper is as follows. After we briefly recall several basic preliminaries in the remainder of this section, we start the next section with the two reducible examples of $H_{g+1,g,4}^L$ for $g = 9$ and $g = 12$.

We then proceed to deal with the irreducibility of $H_{g+1,g,4}^L$ for some low genus $g$, e.g. $g = 10$ or $g = 11$.

For notations and conventions, we usually follow those in [2] and [3]; e.g. $\pi(d,r)$ is the maximal possible arithmetic genus of an irreducible and non-degenerate curve of degree $d$ in $\mathbb{P}^r$. Throughout we work over the field of complex numbers.

Before proceeding, we recall several related results which are rather well-known; cf. [3]. Let $\mathcal{M}_g$ be the moduli space of smooth curves of genus $g$. For any given isomorphism class $[C] \in \mathcal{M}_g$ corresponding to a smooth irreducible curve $C$, there exist a neighborhood $U \subset \mathcal{M}_g$ of the class $[C]$ and a smooth connected variety $\mathcal{M}$ which is a finite ramified covering $h : \mathcal{M} \to U$, as well as varieties $\mathcal{C}$, $\mathcal{W}_d^r$ and $\mathcal{G}_d^r$ proper over $\mathcal{M}$ with the following properties:

1. $\xi : C \to \mathcal{M}$ is a universal curve, i.e. for every $p \in \mathcal{M}$, $\xi^{-1}(p)$ is a smooth curve of genus $g$ whose isomorphism class is $h(p)$,
2. $\mathcal{W}_d^r$ parametrizes the pairs $(p, L)$ where $L$ is a line bundle of degree $d$ and $h^0(L) \geq r + 1$ on $\xi^{-1}(p)$,
3. $\mathcal{G}_d^r$ parametrizes the couples $(p, D)$, where $D$ is possibly an incomplete linear series of degree $d$ and dimension $r$ on $\xi^{-1}(p)$ - which is usually denoted by $g_d^r$.

Let $\tilde{\mathcal{G}}$ ($\tilde{\mathcal{G}}_L$ resp.) be the union of components of $\mathcal{G}_d^r$ whose general element $(p, D)$ of $\tilde{\mathcal{G}}$ ($\tilde{\mathcal{G}}_L$ resp.) corresponds to a very ample (very ample and complete resp.) linear series $D$ on the curve $C = \xi^{-1}(p)$. Note that an open subset
of $\mathcal{H}_{d,g,r}$ consisting of points corresponding to smooth irreducible and non-degenerate curves is a $\mathbb{P}GL(r+1)$-bundle over an open subset of $\tilde{G}$. Hence the irreducibility of $\tilde{G}$ guarantees the irreducibility of $\mathcal{H}_{d,g,r}$. Likewise, the irreducibility of $\tilde{G}_L$ ensures the irreducibility of $\mathcal{H}_{d,g,r}^L$.

We also make a note of the following well-known facts regarding the schemes $G_d^r$ and $W_d^r$; cf. [1, Proposition 2.7, 2.8], [11, 2.a], [3, Ch. 21, §3, 5, 6, 11, 12] and [9, Theorem 1]. Following classical terminology, a base-point-free linear series $g_d^r$ which is not very ample ($r \geq 2$) on a smooth curve $C$ is called birationally very ample when the morphism $C \to \mathbb{P}^r$ induced by the $g_d^r$ is generically one-to-one (or birational) onto its image; cf. [10, p. 570],

**Proposition 1.2.** For non-negative integers $d$, $g$ and $r$, let $\rho(d,g,r) := g - (r + 1)(g - d + r)$ be the Brill-Noether number.

1. The dimension of any component of $G_d^r$ is at least $3g - 3 + \rho(d,g,r)$ which is denoted by $\lambda(d,g,r)$. Moreover, if $\rho(d,g,r) \geq 0$, there exists a unique component $G_0$ of $\tilde{G}$ which dominates $M$ (or $M_g$).
2. Suppose $g > 0$ and let $X$ be a component of $G_d^r$ whose general element $(p,D)$ is such that $D$ is a birationally very ample linear series on $\xi^{-1}(p)$. Then
   \[
   \dim X = 3g - 3 + \rho(d,g,2) = 3d + g - 9.
   \]

**Remark 1.3.** (1) In the Brill-Noether range, the unique component $G_0$ of $\tilde{G}$ (and the corresponding component $\mathcal{H}_0$ of $\mathcal{H}_{d,g,r}$ as well) which dominates $M$ or $M_g$ is called the “principal component”.

(2) In the range $d \leq g + r$ inside the Brill-Noether range, the principal component $G_0$ which has the expected dimension is one of the components of $\tilde{G}_L$ (cf. [11, 2.1 page 70]), and therefore $\tilde{G}_L$ or $\mathcal{H}_{d,g,r}^L$ and hence $\mathcal{H}_{d,g,r}$ is non-empty. If one can show that $G_0$ is the only component of $\tilde{G}_L$ ($\tilde{G}$ resp.), the irreducibility of $\mathcal{H}_{d,g,r}^L$ ($\mathcal{H}_{d,g,r}$ resp.) would follow immediately.

(3) However outside the Brill-Noether range, such a distinguished component does not exist and this is one of the reasons why the problem becomes rather subtle.

We will utilize the following upper bound of the dimension of an irreducible component of $W_d^r$, which was proved and used effectively in [13]. A base-point-free linear series $g^r_d$ on $C$ is called compounded of an involution (compounded for short) if the morphism induced by the linear series gives rise to a non-trivial covering map $C \to C'$ of degree $k \geq 2$.

**Proposition 1.4** ([13, Proposition 2.1]). Let $d$, $g$ and $r \geq 2$ be positive integers such that $d \leq g + r - 2$ and let $\mathcal{W}$ be an irreducible component of $W_d^r$. For a general element $(p,L) \in \mathcal{W}$, let $b$ be the degree of the base locus of the line bundle $L = |D|$ on $C = \xi^{-1}(p)$. Assume further that for a general $(p,L) \in \mathcal{W}$ the curve $C = \xi^{-1}(p)$ is not hyperelliptic. If the moving part of $L = |D|$ is

(a) very ample and $r \geq 3$, then $\dim \mathcal{W} \leq 3d + g + 1 - 5r - 2b$;
(b) birationally very ample, then \( \dim \mathcal{W} \leq 3d + g - 1 - 4r - 2b; \)
(c) compounded, then \( \dim \mathcal{W} \leq 2g - 1 + d - 2r. \)

2. Irreducibility of \( \mathcal{H}_{g+1, g, 4} \)

We first recall several relevant results from [17, Theorem 2.1 and Theorem 2.2].

**Remark 2.1.**
(1) Every non-empty \( \mathcal{H}_{g+1, g, 4} \) is irreducible unless \( g = 9. \)
(2) \( \mathcal{H}_{g+1, g, 4} = \emptyset \) for \( g \leq 8. \)
(3) For \( g = 9, \mathcal{H}_{10, 9, 4} = \mathcal{H}_{10, 9, 4} \) is reducible with two components of dimensions 42 and 43.
(4) For \( g = 10, \mathcal{H}_{11, 10, 4} = \mathcal{H}_{11, 10, 4} \) is irreducible of the expected dimension 46.
(5) For \( g = 12, \mathcal{H}_{13, 12, 4} \) is reducible with two components of the same expected dimension 54, whereas \( \mathcal{H}_{13, 12, 4} \) is irreducible.
(5) The non-emptiness \( \mathcal{H}_{g+1, g, 4} \) (hence \( \mathcal{H}_{g+1, g, 4} \) as well) and the existence of the extra components in the reducible cases above is rather clear from the proof in [17, Proposition 2.2].

We make a note of the following lemma which will avoid unnecessary repetitions in the course of the proof of our result.

**Lemma 2.2.** The residual series \( \mathcal{E} = |K_C - D| \) of a possibly incomplete very ample (and special) linear series \( D \) cannot induce a double covering \( C \twoheadrightarrow E \) onto a curve of genus \( h \geq 0 \) so that the base-point-free part of \( \mathcal{E} \) is a pull back of a non-special linear series on the target curve \( E \) via \( \eta \).

**Proof.** Note that the complete \( |D| = g^r_C \) is very ample if \( D \) is. Let \( C \twoheadrightarrow E \subset \mathbb{P}^s \) be the double covering induced by the base-point-free part of \( \mathcal{E} = |K_C - D| \) and let \( h \) be the genus of the curve \( E \). We may assume \( s := \dim \mathcal{E} \geq 2 \) and \( h \geq 1 \) since for \( s = 1 \) or \( h = 0 \), \( C \) is hyperelliptic and a hyperelliptic curve does not have a special very ample linear series.

Let \( \Delta \) be the base locus of \( \mathcal{E} \) and \( |\mathcal{E} - \Delta| = \eta^*(\mathcal{F}) \) for some complete, non-special and base-point-free \( \mathcal{F} = g^r_C \) on \( E \) where \( s = g - d + r - 1 \). Since \( \mathcal{F} \) is non-special, \( s = f - h. \) Choose any \( t \in E \), set \( u + v := \eta^*(t) \) and we have

\[
\begin{align*}
    s + 1 & \leq \dim \eta^*(|g^r_C + t|) \leq \dim \eta^*(|\mathcal{F} + t|) = \dim \eta^*(\mathcal{F}) + u + v \\
    & = \dim |\mathcal{E} - \Delta + u + v| = \dim |K_C - D - \Delta + u + v| \\
    & \leq \dim |K_C - (D - u - v)|.
\end{align*}
\]

By Riemann-Roch, it follows that

\[
\dim |D - u - v| = d - 2 - g + h^0(C, K_C - (D - u - v)) \geq r - 1
\]

and hence \( |D| \) is not very ample, a contradiction. \( \Box \)
Since the irreducibility (or the reducibility) of $H_{g+1,4}^{r+1}$ were treated fully in [17] for $g = 9, 10, 12$ as in Remark 2.1, we focus on the three remaining cases $g = 11, g = 13$ and $g = 14$ which are also outside the Brill-Noether range.

We will use the following dimension estimate of a component $W \subset W_{g+1}^{r+1}$ corresponding to a possible extra component of $H_{g+1,4}^{r+1}$ other than the one corresponding to the irreducible $H_{g+1,4}^{r+1}$.

**Lemma 2.3.** Assuming that $H_{g+1,4}^{r+1}$ is not irreducible, we let $H$ be an extra component of $H_{g+1,4}^{r+1}$ other than $H_{g+1,4}^{r+1}$. Let $G \subset G_{g}^{r}$ be the component corresponding to $H$, i.e. $H$ is a $\mathbb{P}GL(5)$-bundle over $G$ and $G \neq G_{L}$. Let $W \subset W_{g+1}^{r+1}$ be the component containing the image of the natural rational map $G \to W_{g+1}^{r}$ with $\iota(D) = |D|$. We also let $W^{v} \subset W_{g-3}^{r-2}$ be the locus consisting of the residual series of elements in $W$, i.e.

$$W^{v} = \{(p, \omega_{C} \otimes L^{-1}) : (p, L) \in W\}.$$ 

Let $b$ be the degree of the base locus of a general element of $W^{v}$. Then $r \geq 5$ and we have the following dimension estimate of the locus $W$.

1. If the base-point-free part of a general element of $W^{v}$ is very ample, then $b = 0$ and

$$\dim W = \dim W^{v} = 4g - 5r + 2.$$ 

2. If the base-point-free part of a general element of $W^{v}$ is birationally very ample, then

$$4g - 5r + 2 \leq \dim W = \dim W^{v} \leq 4g - 4r - 2 - 2b.$$ 

In particular, if $r = 5$ we have $b = 0$.

3. If the base-point-free part of a general element of $W^{v}$ is compounded,

$$4g - 5r + 2 \leq \dim W = \dim W^{v} \leq 3g - 2r.$$ 

In particular we have $g \leq 3r - 2$.

**Proof.** By Remark 2.1(1), a general element $(p, D) \in G$ is such that $D$ is an incomplete $g_{4+1}^{4}$ on $C = \xi^{-1}(p)$ hence $r := \dim |D| \geq 5$.

1. By Proposition 1.2(1) and Proposition 1.4(a), we have

$$\lambda(g + 1, g, 4) = 4g - 18 \leq \dim G \leq \dim G(4, r) + W$$

$$= \dim G(4, r) + \dim W^{v}$$

$$\leq 5(r - 4) + 3(g - 3) + g + 1 - 5(r - 2) - 2b$$

$$= 4g - 18 - 2b$$

and hence $b = 0$ and

$$\dim W = \dim W^{v} = 4g - 18 - 5(r - 4) = 4g - 5r + 2.$$
(2) By Proposition 1.2(1) and Proposition 1.4(b), we have
\[ 4g - 18 \leq \dim \mathcal{G} \leq \dim \mathcal{G}(4, r) + \mathcal{W} = \dim \mathcal{G}(4, r) + \dim \mathcal{W}^\vee \]
\[ \leq 5(r - 4) + 3(g - 3) + g - 1 - 4(r - 2) - 2b \]
\[ = 4g - 22 + r - 2b. \]

dence
\[ 4g - 5r + 2 \leq \dim \mathcal{W} = \dim \mathcal{W}^\vee \leq 4g - 4r - 2 - 2b. \]

(3) By Proposition 1.4(c), we have
\[ 4g - 18 \leq \dim \mathcal{G} \leq \dim \mathcal{G}(4, r) + \mathcal{W} = \dim \mathcal{G}(4, r) + \dim \mathcal{W}^\vee \]
\[ \leq 5(r - 4) + 2g - 1 + (g - 3) - 2(r - 2) \]
\[ = 3g + 3r - 20. \]

implying
\[ 4g - 5r + 2 \leq \dim \mathcal{W} = \dim \mathcal{W}^\vee \leq 3g - 2r. \]

\[ \square \]

**Remark 2.4.** The following lemma is rather technical but is useful in transferring the original problem into lower degree cases. Indeed it is a slight variation of a claim which appeared in the course of the proof of a key lemma in [18, Lemma 2.3]. For the convenience of the readers, a similar proof is provided.

**Lemma 2.5.** Assuming that \( H_{g+1, g, 4} \) is not irreducible, we let \( H \) be an extra component of \( H_{g+1, g, 4} \) other than \( H_{g+1, g, 4}^\mathcal{C} \). Let \( \mathcal{G} \subset \mathcal{G}_d^\mathcal{C} \) be the component corresponding to \( H \). Let \( \mathcal{W} \subset \mathcal{W}_{r+1} \) and \( \mathcal{W}^\vee \subset \mathcal{W}_{r-2} \) be as in Lemma 2.3. Assume further that a general element of \( \mathcal{W}^\vee \) is base-point-free and birationally very ample. Then there is a locus \( Z \subset \mathcal{W}_{r-3}^\vee \) such that
\[ \dim Z = \dim \mathcal{W} = \dim \mathcal{W}^\vee. \]

**Proof.** We consider the following obvious diagram:
\[
\begin{array}{ccc}
\mathcal{W}_{g-5}^{r-3} \times \mathcal{M}_2 & \xrightarrow{q} & \mathcal{W}_{g-5}^{r-3} \\
\downarrow \pi & & \\
\mathcal{W}_{g-5}^{r-3} & &
\end{array}
\]

where \( q(\mathcal{E}', \mathcal{O}_C(R+S)) = \mathcal{E}' \otimes \mathcal{O}_C(R+S) \) and \( \pi(\mathcal{E}', \mathcal{O}_C(R+S)) = \mathcal{E}' \). Since a general element \( (p, \mathcal{E}) \in \mathcal{W}^\vee \subset \mathcal{W}_{g-3}^{r-2} \subset \mathcal{W}_{g-3}^{r-3} \) is birationally very ample and base-point-free, \( q^{-1}(\mathcal{E}) \neq \emptyset \) for a general \( (p, \mathcal{E}) \in \mathcal{W}^\vee \). Let \( \Sigma \) be a component of \( q^{-1}(\mathcal{W}^\vee) \) such that \( q(\Sigma) = \mathcal{W}^\vee \). Since a general \( (p, \mathcal{E}) \in \mathcal{W}^\vee \) is assumed to be birationally very ample, we see that \( \dim q^{-1}(\mathcal{E}) = 0 \) and hence
\[ \dim \Sigma = \dim \mathcal{W}^\vee. \]
We set \( Z := \pi(\Sigma) \subset \mathcal{W}_{g-5}^{r-3} \) and consider the following induced diagram:

\[
\mathcal{W}_{g-5}^{r-3} \times \mathcal{W}_2 \supset \Sigma \xrightarrow{q} \mathcal{W}^\vee \subset \mathcal{W}_{g-3}^{r-2} \subset \mathcal{W}_{g-3}^{r-3} \xrightarrow{\pi} \mathcal{W}_{g-5}^{r-3} \supset Z
\]

We now argue that \( \dim \pi^{-1}(\mathcal{E}') = 0 \) for a general \((p, \mathcal{E}') \in Z\) as follows. We choose \((p, \mathcal{E}) \in \mathcal{W}^\vee\) and fix \((p, \mathcal{E}') \in Z\) such that \((\mathcal{E}', \mathcal{O}_C(R+S)) \in q^{-1}(\mathcal{E})\) for some \(R, S \in C = \xi^{-1}(p)\), i.e. \(\mathcal{E} \cong \mathcal{E}' \otimes \mathcal{O}_C(R+S)\). Recall that by our initial setting, \(\omega_C \otimes \mathcal{E}'^{-1} = |D| \in \mathcal{W} \subset \mathcal{W}_{g+1}\) is a very ample line bundle for a general \(\mathcal{E} \in \mathcal{W}^\vee \subset \mathcal{W}_{g-3}^{r-2}\). We also note that the very ample, base-point-free and complete linear system \(|D| = \omega_C \otimes \mathcal{E}'^{-1} = \omega_C \otimes \mathcal{E}'^{-1} \otimes \mathcal{O}_C(-R - S)\) is a subsystem of \(\omega_C \otimes \mathcal{E}'^{-1}\). Hence \(\omega_C \otimes \mathcal{E}'^{-1}\) is birationally very ample; otherwise the isomorphism induced by the very ample \(D\) on \(C = \xi^{-1}(p)\) onto its image factors non-trivially through the morphism induced by \(\omega_C \otimes \mathcal{E}'^{-1}\), which is an absurdity. Therefore by noting that \(\omega_C \otimes \mathcal{E}'^{-1} = g_{g+1}^{r+1}\), there are only finitely many choices of \(\mathcal{O}_C(-\tilde{R} - \tilde{S})\)’s such that

\[
\omega_C \otimes \mathcal{E}'^{-1} \otimes \mathcal{O}_C(-\tilde{R} - \tilde{S}) = g_{g+1}^{r+1} \in \mathcal{W} \subset \mathcal{W}_{g+1}^{r+1},
\]

i.e. \((\mathcal{E}', \mathcal{O}_C(\tilde{R} + \tilde{S})) \in \Sigma\) or equivalently \(\mathcal{E}' \otimes \mathcal{O}_C(\tilde{R} + \tilde{S}) \in \mathcal{W}^\vee\), which implies \(\dim \pi^{-1}(\mathcal{E}') = 0\). By semi-continuity, we have \(\dim \pi^{-1}(\mathcal{E}') = 0\) for a general \((p, \mathcal{E}') \in Z\) and hence

\[
\dim Z = \dim \Sigma.
\]

The following theorem will be used in the proof of Theorem 2.7 for the case \(g = 14\). On the other hand, as far as the author knows, \(\mathcal{H}_{11,14,3}\) is one of rare examples of irreducible Hilbert schemes \(\mathcal{H}_{d,g,3}\) of expected dimension with a very negative Brill-Noether number.

**Theorem 2.6.** *The Hilbert scheme \(\mathcal{H}_{11,14,3}\) is irreducible of the expected dimension 44.*

**Proof.** We first remark that a general \(C \in \mathcal{H}_{g-3,g,3} = \mathcal{H}_{11,14,3}\) is residual to a curve \(D \subset \mathbb{P}^3\) of degree \(e = 5\) and genus \(h = 2\) in the complete intersection of two quartics. Since every smooth curve \(C\) of genus \(g = 14\) of degree \(d = 11\) in \(\mathbb{P}^3\) lies on at least \(h^0(\mathbb{P}^3, \mathcal{O}(4)) - h^0(C, \mathcal{O}(4)) = 35 - (44 - 14 + 1) = 4\) independent quartics, the residual curve in a complete intersection of two quartics containing \(C\) is a curve \(D\) of degree \(e = 5\) and genus \(h = 2\) by the well-known formula relating degrees and genus of directly linked curves in \(\mathbb{P}^3\):

\[
2(g - h) = (s + t - 4)(d - e).
\]

Consider the locus

\[
\Sigma \subset \mathbb{G}(1, \mathbb{P}(H^0(\mathbb{P}^3, \mathcal{O}(4)))) = \mathbb{G}(1, 34)
\]
of pencils of quartic surfaces whose base locus consists of a curve of degree \( d = 11 \) and genus \( g = 14 \) and a quintic of genus \( h = 2 \), together with the two obvious maps

\[
\mathbb{G}(1, 34) \supset \Sigma \xrightarrow{\pi_C} \mathcal{H}_{11, 14, 3} \xrightarrow{\pi_D} \mathcal{H}_{5, 2, 3}
\]

A quintic \( D \subset \mathbb{P}^3 \) of genus \( h = 2 \) lies on at least

\[
h^0(\mathbb{P}^3, \mathcal{O}(4)) - h^0(D, \mathcal{O}(4)) = 35 - 19 = 16
\]

independent quartics. Note that \( C \in \mathcal{H}_{11, 14, 3} \) is directly linked to \( D \in \mathcal{H}_{5, 2, 3} \) which in turn is directly linked to a line \( L \) via complete intersection of a quadric and a cubic. From the basic relation

\[
\dim H^1(\mathbb{P}^3, \mathcal{I}_C(m)) = \dim H^1(\mathbb{P}^3, \mathcal{I}_D(s + t - 4 - m))
\]

where \( C \) and \( D \) are directly linked via complete intersection of surfaces of degrees \( s \) and \( t \), we have

\[
h^1(\mathbb{P}^3, \mathcal{I}_C(4)) = h^1(\mathbb{P}^3, \mathcal{I}_D(0)) = h^1(\mathbb{P}^3, \mathcal{I}_L(2 + 3 - 4 - 0)) = 0
\]

and

\[
h^1(\mathbb{P}^3, \mathcal{I}_D(4)) = h^1(\mathbb{P}^3, \mathcal{I}_L(2 + 3 - 4 - 4)) = 0.
\]

Therefore \( \pi_D \) is generically surjective with fibers open subsets of \( \mathbb{G}(1, 15) \). Since \( \dim \mathcal{H}_{5, 2, 3} \) is known to be irreducible (cf.\cite{7} or \cite{11, page 51}), it follows that \( \Sigma \) is irreducible and

\[
\dim \Sigma = \dim \mathbb{G}(1, 15) + \dim \mathcal{H}_{5, 2, 3} = 28 + 4 \cdot 5 = 48.
\]

On the other hand, since every smooth curve \( C \) of degree \( d = 11 \) and \( g = 14 \) lies on exactly 4 independent quartics by the above, \( \pi_C \) is generically surjective with fibers open in \( \mathbb{G}(1, 3) \). Finally it follows that \( \mathcal{H}_{11, 14, 3} \) is irreducible of dimension

\[
\dim \Sigma - \dim \mathbb{G}(1, 3) = 44 = 4 \cdot 11.
\]

\[ \Box \]

**Theorem 2.7.** For \( g = 11, 13 \) and 14

1. \( \mathcal{H}_{g+1,g,4} \) is irreducible and \( \mathcal{H}_{g+1,g,4} = \mathcal{H}_{g+1,g,4}^L \).
2. \( \dim \mathcal{H}_{g+1,g,4} = \lambda(g + 1, g, 4) + \dim \mathbb{P}GL(5) \),
3. and is generically reduced.

**Proof.** We retain all the notations used in Lemma 2.3; \( \mathcal{H} \) is an extra component of \( \mathcal{H}_{g+1,g,4} \) other than \( \mathcal{H}_{g+1,g,4}^L \). \( \mathcal{G} \subset \mathcal{G}^r_d \) is the component corresponding to \( \mathcal{H} \), \( \mathcal{W} \subset \mathcal{W}^r_{g+1} \) is the component corresponding to \( \mathcal{G} \) where \( r = \dim |D| \) for a general \( (p,D) \in \mathcal{G} \) and so on.

\([g = 11]\) Note that \( r = 5 \) since there does not exist a special \( g_9^{5,1} = g_1^{5,1} \) on a non-hyperelliptic curve by Clifford’s theorem; a hyperelliptic curve cannot be embedded in \( \mathbb{P}^r, \ r \geq 2 \) as a curve of degree \( g + 1 \) with a special hyperplane
series. We also note that a general element of $W^\vee$ is neither very ample nor birationally very ample; if so, the base-point-free part of a general $E = g^3_8 \in W^\vee$ induces a birational morphism (or an embedding) into $\mathbb{P}^3$ and the genus of $C$ is at most $\pi(8, 3) = 9$ by the Castelnuovo genus bound. Therefore a general element of $W^\vee$ is compounded. We further note that $E$ is base-point-free, otherwise $E$ has at least degree two base locus in which case the Clifford’s theorem applies. Therefore $E$ induces degree two morphism $C \xrightarrow{\eta} E$ onto an elliptic curve $E \subset \mathbb{P}^3$ and $E = \eta^*(F)$ for some non-special $F = g^3_4$ on the elliptic curve $E$, which is impossible by Lemma 2.2. Hence there is no extra component of $H_{g+1, g, 4}$ other than $H_{g+1, g, 4}^\Sigma$, which is already irreducible and of expected dimension

One easily sees that $H_{12, 11, 4}^\Sigma = H_{12, 11, 4}$ is non-empty. A non-singular model of a plane curve of degree 8 with one ordinary 4-fold points and 4 nodes embeds into a Del Pezzo surface in $\mathbb{P}^4$ by the linear system of cubics through these 5 points as a smooth curve of degree $d = 3 \cdot 8 - 1 \cdot 4 - 4 \cdot 2 = 12$ and genus $g = 21 - 6 - 4 \cdot 1 = 11$; cf. [21, Theorem 1.1].

For $g = 13$, we also have $r = \dim |D| = 5$ for a general $(p, D) \in G$ since $\pi(14, r) \leq 11$ for $r \geq 6$.

(a) Assume that the morphism induced by $E = |K_C - D| = g^3_{10}$ is compounded. If $E$ is base-point-free, then $E$ induces a double covering $C \xrightarrow{\iota} E \subset \mathbb{P}^3$ onto a curve $E$ of genus at most two (by the Castelnuovo genus bound applied to $E$) and $E = g^3_{10} = \eta^*(F)$ for some $F = g^3_5$, which is complete, non-special and base-point-free linear series on $E$. However this is impossible by Lemma 2.2.

Suppose that a general element $E \in W^\vee$ has a non-empty base locus $\Delta$.

If $\deg \Delta = 1$, then the moving part of $E = g^3_{10}$ is a $g^3_9$ inducing a 3-sheeted map $C \xrightarrow{\Delta} D$ onto a rational normal curve $D \subset \mathbb{P}^3$, i.e. $C$ is trigonal. Let $g^3_1$ be the unique trigonal pencil (by Castelnuovo-Severi inequality) on $C$. Note that $E = |K_C - D| = 3g^1_3 + \Delta$ and take $\Gamma \in C_2$ such that $\Delta + \Gamma \in g^3_1$. We then have $|E + \Gamma| = |K_C - D + \Gamma| = 4g^1_3$ and it follows that $|D - \Gamma| = |K_C - 4g^1_3| = g^4_{12}$ and therefore $D$ is not very ample, a contradiction.

In case $\deg \Delta = 2$, $|E - \Delta| = g^3_8$ induces a double covering onto an elliptic curve, which is impossible by Lemma 2.2. The case $\deg \Delta \geq 3$ never occurs by obvious reasons; Clifford’s theorem etc.. Therefore we conclude that a general element of $W^\vee$ cannot be compounded.

(b) Suppose that the moving part of a general element of $W^\vee \subset W^3_{g-3}$ is very ample and take a general $|K_C - D| = g^3_{10} \in W^\vee$. Note that the the genus
$g = 13$ is larger than the second Castelnuovo genus bound $\pi_1(10, 3)$;

$$\pi_1(10, 3) = \frac{(g - 4)(g - 5)}{6} = 12 < g = 13 < \pi(10, 3) = 16$$

and hence by basic Castelnuovo theory the curve embedded by a very ample $g^3_{10}$ must lie on a quadric surface in $\mathbb{P}^3$; cf. [11, Corollary 3.14, page 97]. However there is no integer pair $(a, b)$ satisfying $a + b = 10$ and $(a - 1)(b - 1) = 13 = g$.

(c) Therefore the moving part of a general element of $W^\vee \subset W^3_{g-3}$ is birationally very ample and let $b$ be the degree of the base locus $B$ of a general element of $W^\vee$. By Lemma 2.3(2), we have $b = 0$ and

$$4g - 23 \leq \dim W = \dim W^\vee \leq 4g - 22. \quad (1)$$

By Lemma 2.5, we have a irreducible closed locus $Z \subset W^2_{g-5}$ such that $\dim Z = \dim W^\vee = \dim W$. Note that the base-point-free part of general element of $Z$ is not very ample; $g = 13$ is not a genus of a smooth plane curve. If the base-point-free part of general element of $Z$ is birationally very ample, then by Proposition 1.4(b) (applied to the locus $Z$), we have

$$\dim Z = \dim W \leq 3(g - 5) + g - 1 - 8 = 4g - 24,$$

which is not compatible with the above (1). Therefore the only remaining possibility is that a general element of $Z \subset W^2_{g-5}$ is compounded and let $\Delta$ be the base locus of a general element $F = g^2_2 \in Z$ with $\delta = \deg \Delta$. One of the following may occur; note that $\delta \leq 2$ and $\delta \neq 1$ by Clifford’s theorem etc.

(1) $C$ is a double covering of a curve $E$ of genus 2 with a two sheeted map $C \xrightarrow{\zeta} E$ and $F = \zeta^*(g^2_4)$; $\delta = 0$.

(2) $C$ is a double covering of a smooth plane quartic $F$ with a two sheeted map $C \xrightarrow{\eta} F$ and $F = \eta^*(|K_F|) = \eta^*(g^2_4)$; in the case $F$ is a pull-back of the special $|K_F|$ on the quartic $F$ and $\delta = 0$.

(3) $C$ is bi-elliptic with a bi-elliptic covering $C \xrightarrow{\phi} E$ and $F = \phi^*(g^2_3) + \Delta$; $\delta = 2$.

(4) $C$ is trigonal and $F = 2g^1_3 + \Delta$; $\delta = 2$.

(5) $C$ a 4-gonal curve with $F = 2g^1_4$; $\delta = 0$.

We now choose a general $(F, p) \in Z \subset W^2_{g-5}$ and set

$$|F + \Gamma| \in W^\vee \subset W^3_{g-3}$$

where $\Gamma = t + s \in C_2$ is obtained from a singularity of the image curve of the morphism $\xi^{-1}(p) = C \to \mathbb{P}^3$ induced by a birationally very ample and base-point-free $g^3_{10} = |F + \Gamma| = E = |K_C - D| \in W^\vee$.

(1) and (3): One may argue that the residual series $|D| = |K_C - F - \Gamma|$ is not very ample, virtually in the same manner as in the proof of Lemma 2.2 as follows. If $C \xrightarrow{\zeta} E$ is a double covering onto a curve $E$ of genus 2, then

$$|F| = \zeta^*(g^2_4) = |E - t - s| = |K_C - D - t - s|$$
and hence
\[ |D| = |K_C - \zeta^*(g_4^2) - t - s|. \]
We take \( r' + s' \in C_2 \) which is the conjugate divisor of the divisor \( t + s \in C_2 \) with respect to the double covering \( \zeta \). Then we have
\[ |D - t' - s'| = |K_C - \zeta^*(g_4^2) - t - s - t' - s'| = |K_C - \zeta^*(g_4^1)| = g_{12}^4 \]
hence \( |D| \) is not very ample. The case (3) is almost identical to (1) which we omit.

For the case (2), a calculation similar to the above or applying Proposition 1.4(c) to the locus \( Z \) fails to work. Instead we argue as follows. Recall that under our current circumstance, the double covering \( \eta \) onto a smooth plane quartic is induced by a (general) element of \( Z \subset W_2^2 \), which is a subseries of a birationally very ample base-point-free \( E \in W_9^3 \subset W_{10}^3 \). To be precise, consider the following diagram which is adopted to the current situation which appeared in the proof of Lemma 2.5;
\[
\begin{align*}
\mathcal{W}_8^2 \times \mathcal{W}_2 & \supset \Sigma \\
\downarrow & \pi \\
\mathcal{W}_8^2 & \supset Z \\
\downarrow & \zeta \\
\mathcal{X}_{2,3} & \subset \mathcal{M}_g
\end{align*}
\]
where \( \mathcal{X}_{n,\gamma} \) denotes the locus in \( \mathcal{M}_g \) corresponding to curves which are \( n \)-fold coverings of smooth curves of genus \( \gamma \). By de Franchis theorem (cf. [12]), the fiber in \( Z \) of the rational map \( \zeta \) over a general class \( [C] \in \zeta(Z) \subset \mathcal{X}_{2,3} \) is finite. As we saw in the proof of Lemma 2.5, \( \pi \) is a generically finite map and hence over \( (E', p) \in Z \) we have finitely many \( O_C(R + S)'s \) in the second factor of the locus \( \Sigma \) so that \( \mathcal{E}' \otimes O_C(R + S) \in \mathcal{W}^\vee \). Therefore upon choosing a general \( [C] \in \zeta(Z) \subset \mathcal{X}_{2,3} \), we arrive at an element \( \mathcal{E} \in \mathcal{W}^\vee \). The ambiguities in choosing an element among the finite fiber of \( \zeta \) as well as the fiber of \( \pi \) do not affect the following dimension count. In other words, we arrive at finitely many \( \mathcal{E} \in \mathcal{W}^\vee \) and all the \( \mathcal{E} \)'s obtained in this way lie on \( W_{10}^3(C) \). By the well-known Riemann’s moduli count [20, Satz 1]
\[ \dim \mathcal{X}_{n,\gamma} \leq 2g + (2n - 3)(1 - \gamma) - 2, \]
one has
\[ 4g - 23 \leq \dim \mathcal{W}^\vee = \dim \mathcal{W} \leq \dim \mathcal{X}_{2,3} \leq 2g - 4, \]
a contradiction.

(4) Since a trigonal curve \( C \) of genus \( g \geq 5 \) has a unique trigonal pencil \( g_3^1 \), we have the following well defined rational map induced from the construction of the sublocus \( Z \subset \mathcal{W}_8^2 \).
On the Hilbert scheme of smooth curves in $\mathbb{P}^4$ of degree $g + 1$

\[ \mathcal{Z} \xrightarrow{\psi} \mathcal{W}_{g,3}^1 \times \mathcal{M} \xrightarrow{\pi_2} \mathcal{W}_{3}^1 \xrightarrow{\kappa} \mathcal{M}_{g,3}^1 \]

where $\pi_2$ is the second projection and $\kappa$ is a natural birational map. We now claim that the composition $\tau : \mathcal{Z} \rightarrow \mathcal{M}_{g,3}^1$ of the above maps is a generically finite map.

Take the residual series of $|\mathcal{D}| \in \mathcal{W}$;

\[ |K_C - \mathcal{D}| = \mathcal{E} = g_1^3 = |\mathcal{F} + \Gamma| = |2g_3^1 + \Delta + \Gamma| = |2g_3^1 + \Delta + R + S|, \]

so that

\[ |\mathcal{D}| = |K_C - 2g_3^1 - (R + S) - \Delta|. \]

Note that $\dim |2g_3^1 + U + V| = \dim |2g_3^1| = 2$ for any $U + V \in \mathcal{C}_2$ and hence

\[ \dim |K_C - 2g_3^1 - (R + S)| = \dim |K_C - 2g_3^1| - 2 = 6. \]

We also note that a very ample $\mathcal{D}$ is a subseries of $|K_C - 2g_3^1 - (R + S)|$ and hence the series $|K_C - 2g_3^1 - (R + S)|$ is birationally very ample, which is also base-point-free. Therefore it follows that there exists only finitely many choice of $\Delta$’s subject to the condition

\[ 5 = \dim |\mathcal{D}| = \dim |K_C - 2g_3^1 - (R + S) - \Delta| = \dim |K_C - 2g_3^1 - (R + S)| - 1. \]

and hence $\tau$ is generically finite. By this claim follows that

\[ 4g - 23 \leq \dim \mathcal{Z} \leq \dim \mathcal{M}_{g,3}^1 = 2g + 1, \]

which is a contradiction.

(5) In this case we have $\mathcal{F} = 2g_4^1$ for a general $\mathcal{F} \in \mathcal{Z}$, which is complete.

Note that on a 4-gonal curve $C$ of genus $g \geq 10$ which is not bi-elliptic, there exists a unique $g_4^1$ and hence we have a natural generically injective rational map

\[ \mathcal{Z} \xrightarrow{\pi} \mathcal{M}_{g,4}^1. \]

and it follows that

\[ 4g - 23 \leq \dim \mathcal{Z} \leq \dim \mathcal{M}_{g,4}^1 = 2g + 3 \]

and hence the rational map $\pi$ is dominant. Recall that on a general 4-gonal curve $C$, $|K_C - 2g_4^1|$ is very ample; cf. [4]. Hence it follows that

\[ \dim |\mathcal{D}| = \dim |K_C - \mathcal{E}| = \dim |K_C - \mathcal{F} - \Gamma| = \dim |K_C - 2g_4^1 - R - S| = \dim |K_C - 2g_4^1| - 2 = 6 - 2 = 4 \]

which is a contradiction.

$[g = 14]$ As in the cases of lower $g$, we have $r = 5$, otherwise the Castelnuovo bound for a very ample $g_{15}^6 = g_{g+1}^6$ is $\pi(15, 6) = 13$ which is less than $g = 14$.

(a) If a general element of $\mathcal{W}_g^\vee$ is compounded, then by Lemma 2.3 (3), $g \leq 3r - 2 = 13$, which is impossible.
(b) If a general element of $\mathcal{W}^r \subset \mathcal{W}_{11}^3$ is very ample, then $\dim \mathcal{W}^r = 4g - 23$ by Lemma 2.3 (1). Indeed $4g - 23$ is the maximal possible dimension of any $V \subset \mathcal{W}_{11}^3$ consisting of very ample linear series by Proposition 1.4 (a). Therefore it follows that over the locus $\mathcal{W}^r \subset \mathcal{W}_{11}^3$ generically consisting of very ample complete linear series, there is a component $\tilde{\mathcal{H}}$ of the Hilbert scheme $\mathcal{H}_{11,14,3} = \mathcal{H}_{g-3,9,3}$

$$\dim \tilde{\mathcal{H}} = \dim \mathcal{W}^r + \dim \mathbb{P}GL(4) = 4g - 23 + 15 = 48,$$

which is impossible by the irreducibility of $\mathcal{H}_{11,14,3}$ which has dimension $44 = 4 \cdot 11$ by Theorem 2.6.

(c) Therefore a general element of $\mathcal{W}^r$ is birationally very ample which base-point-free by Lemma 2.3 (2). By Lemma 2.5, we take the locus $\mathcal{Z} \subset \mathcal{W}_{g-5}^2$ such that

$$4g - 23 \leq \dim \mathcal{Z} = \dim \mathcal{W}^r = \dim \mathcal{W} \leq 4g - 22.$$

(i) Base-point-free part of a general element of $\mathcal{Z}$ is not very ample since $g = 14$ is not a genus of a smooth plane curve.

(ii) Base-point-free part of a general element of $\mathcal{Z}$ birationally very ample by Proposition 1.4 (2); if so $4g - 23 \leq \dim \mathcal{Z} \leq 3(g - 5) + g - 1 - 4 \cdot 2 = 4g - 24$, a contradiction.

(iii) Therefore the base-point-free part of a general element of $\mathcal{Z}$ is compounded. We list up all the possibilities according to the degree $\delta$ of the base locus $\Delta$ of a general $F \in \mathcal{Z}$.

1. $\delta = 0$; A general $(F, p) \in \mathcal{Z}$ induces a triple covering $C = \xi^{-1}(p) \xrightarrow{\tau} E$ onto an elliptic curve.
2. $\delta = 1$; A general $F \in \mathcal{Z}$ induces a double covering $C \xrightarrow{\tau} E$ onto a curve of genus 2.
3. $\delta = 1$; A general $F \in \mathcal{Z}$ induces a double covering $C \xrightarrow{\tau} E$ onto a non-hyperelliptic curve of genus 3.
4. $\delta = 1$; A general $F \in \mathcal{Z}$ induces a 4-sheeted covering $C \xrightarrow{\tau} E$ onto a rational curve.
5. $\delta = 3$; A general $F \in \mathcal{Z}$ induces a double covering $C \xrightarrow{\tau} E$ onto an elliptic curve.
6. $\delta = 3$; A general $F \in \mathcal{Z}$ induces a triple covering $C \xrightarrow{\tau} E$ onto a rational curve.

Instead of carrying out a precise dimension estimate in all the cases above as we did in the case $g = 13$, we will make straight forward dimension estimate this time. Our estimate is rather crude but this is sufficient for our purpose. By assuming that a general element of $\mathcal{Z}$ is compounded, we have a sequence of rational maps defined as follows.
On the Hilbert scheme of smooth curves in \( \mathbb{P}^4 \) of degree \( g + 1 \)

\[
\begin{align*}
\mathcal{W}_{g-5}^2 & \cup \mathcal{W}_{g-5-\delta}^2 \times \mathcal{M} \\
\mathcal{Z} & \longrightarrow \Lambda \\
\psi & \quad \nexists \quad \varphi \quad \mathcal{K} = \mathcal{X}_{n,\gamma} \quad \hookrightarrow \mathcal{M}_g \\
\{ (\mathcal{F}', \Delta) | \mathcal{F}' + \Delta = \mathcal{F} \in \mathcal{Z} \} & \quad \hookrightarrow \\
\psi & \\
\mathcal{F} & \quad \longmapsto \quad (\mathcal{F}', \Delta)
\end{align*}
\]

\( \psi \) is the map sending \( \mathcal{F} \) to the pair \( (\mathcal{F}', \Delta) \) where \( \mathcal{F}' \) is the moving part of \( \mathcal{F} \) and \( \Delta \) is the base locus. The second dotted arrow \( \varphi \) is the map assigning the base-point-free part \( \mathcal{F}' \) to its isomorphism class in an appropriate \( \mathcal{X}_{n,\gamma} \) determined by the compounded \( \mathcal{F}' \). It is clear that the first arrow \( \psi \) is well defined and generically injective. We stress that \( \varphi \) is also well defined by the Castelnuovo-Severi inequality so that there is only one choice of multiple covering upon choosing a general \( \mathcal{F} \in \mathcal{Z} \). However the fiber of \( \varphi \) over a point in the image may have dimension more than the degrees of freedom choosing the base locus.

For example, in the case (1), \( \Delta = \emptyset \) and there is no second factor and \( \mathcal{K} = \mathcal{X}_{3,1} \subset \mathcal{M}_g \). Given a triple cover of an elliptic curve \( \mathcal{C} \mapsto \mathcal{E} \) represented by a point \( p \in \mathcal{X}_{3,1} \), the fiber of \( \varphi \) over \( p \) is inside \( \tau^*(\mathcal{W}_3^2(E)) = \tau^*(J(E)) \) which is one dimensional. Hence it follows that

\[
4g - 23 \leq \dim \mathcal{Z} \leq \dim \tau^*(J(E)) + \dim \mathcal{X}_{3,1} \leq 1 + 2g - 2
\]

leading to an absurdity. For the remaining possible cases, we may come up with similar numerical absurdities as follows.

(2) \( \delta = 1 \); a general \( \mathcal{F} \in \mathcal{Z} \) induces a double covering \( \mathcal{C} \mapsto \mathcal{E} \) onto a curve \( \mathcal{E} \) of genus 2 and \( \mathcal{F} = \tau^*(g_4^2) + \Delta \).

\[
4g - 23 \leq \dim \mathcal{Z} \leq \dim \tau^*(J(E)) + \dim \mathcal{X}_{2,2} + \delta \leq 2 + 2g - 3 + 1 = 2g
\]

(3) \( \delta = 1 \); a general \( \mathcal{F} \in \mathcal{Z} \) induces a double covering \( \mathcal{C} \mapsto \mathcal{E} \) onto a non-hyperelliptic curve of genus 3 and and \( \mathcal{F} = \tau^*(|K_E|) \).

\[
4g - 23 \leq \dim \mathcal{Z} \leq \dim \tau^*(|K_E|) + \dim \mathcal{X}_{2,3} + \delta \leq 2g - 4 + \delta = 2g - 3
\]

(4) \( \delta = 1 \); a general \( \mathcal{F} \in \mathcal{Z} \) induces a 4-sheeted covering \( \mathcal{C} \mapsto \mathcal{E} \) onto a rational curve.

\[
4g - 23 \leq \dim \mathcal{Z} \leq \dim \mathcal{M}_{1,g,4}^1 + \delta \leq 2g + 3 + 1 = 2g + 4
\]

(5) \( \delta = 3 \); a general \( \mathcal{F} \in \mathcal{Z} \) induces a double covering \( \mathcal{C} \mapsto \mathcal{E} \) onto an elliptic curve.

\[
4g - 23 \leq \dim \mathcal{Z} \leq \dim \tau^*(J(E)) + \dim \mathcal{X}_{2,1} + \delta \leq 2g + 2
\]
(6) \( \delta = 3 \): A general \( F \in \mathcal{Z} \) induces a triple covering \( C \to E \) onto a rational curve.

\[
4g - 23 \leq \dim \mathcal{Z} \leq \dim \mathcal{M}^{1}_{g,3} + \delta \leq 2g + 1 + 3 = 2g + 4
\]

We could have used a variation of Lemma 2.2 in the cases (2) and (5) to deduce that \( \mathcal{D} \) from which \( F \) is induced is not very ample, as we did in the case for \( g = 13 \). Also note that the above estimate is rather rough, i.e. the possible choice of the base locus is usually finite under several other conditions of ours.

For all the three Hilbert schemes we treated, we showed \( \mathcal{H}_{g+1,g,4} = \mathcal{H}^{L}_{g+1,g,4} \) and hence \( \mathcal{H}_{g+1,g,4} \) is irreducible since \( \mathcal{H}^{L}_{g+1,g,4} \) is. On the other hand, in [17, Theorem 2.1], one proves the irreducibility of \( \mathcal{H}^{L}_{g+1,g,4} \) by showing that the locus \( \mathcal{G}^{L} \) corresponding to a component of \( \mathcal{H}^{L}_{g+1,g,4} \) is birational to the locus \( \mathcal{G}' \subset \mathcal{G}^{2}_{g-3} \) corresponding to the Severi variety \( \Sigma_{g-3,g} \), which is irreducible and has the expected dimension. Therefore \( \mathcal{H}_{g+1,g,4} = \mathcal{H}^{L}_{g+1,g,4} \) has the expected dimension.

The generically reducedness of \( \mathcal{H}_{g+1,g,4} = \mathcal{H}^{L}_{g+1,g,4} \) follows from the fact that the dimension of the singular locus of \( \mathcal{G}' \subset \mathcal{G}^{2}_{g-3} \) does not exceed \( g - 8 < \lambda(g+1,g,4) = \lambda(g-3,g,2) = 4g - 18 \); cf. [1, Proposition (2.9)]. Thus \( \mathcal{G}' \) is generically reduced and since \( \mathcal{G}^{L} \) is birational to \( \mathcal{G}' \) it follows that \( \mathcal{H}_{g+1,g,4} = \mathcal{H}^{L}_{g+1,g,4} \) is also generically reduced. \( \square \)

**Remark 2.8.** (1) It should be remarked that for \( g = 15 \), one can show the irreducibility of \( \mathcal{H}_{g+1,g,4} \) by a similar method we used for the case \( g = 14 \). In fact, one may show that the Hilbert scheme \( \mathcal{H}_{12,15,3} = \mathcal{H}_{g-3,g,3} \) is irreducible of the expected dimension by using the irreducibility of \( \mathcal{H}_{8,5,3} \) whose general element is directly linked to the one in \( \mathcal{H}_{12,15,3} \) via complete intersection of a quartic and a quintic. The irreducibility of \( \mathcal{H}_{8,5,3} \) is known by [7] or [15]. We leave the details for interested readers.

(2) Note that \( \rho(g+1,g,4) = 0 \) for \( g = 15 \) and one may expect that the same tactics using linkage theory as above or as the case \( g = 14 \) may work for \( g \geq 16 \) in general. However, when the genus \( g \) and the degree \( d \) of the family of curves in question is large, the curve often needs to lie on surfaces of rather high degree. Usually such curves are not necessarily linked to another curve which is easier to describe or we know much of.
