Abstract. This research aims to investigate the effect of inlet air humidity, drying temperature and feed composition on the properties of orange juice spray dried powder. Maltodextrin (DE10-12) was used as carrier material. Full factorial design was applied to this research. Inlet air with humidity of 10 g/kg dry air and 20 g/kg dry air, inlet drying air temperature of 140°C 160°C and 180°C and feed concentration of 40°Brix which varied the weight ratio of orange juice solid content to maltodextrin of 1:3 and 1:4.5 were examined. All spray drying conditions were performed in replicate. Ascorbic acid, moisture content water activity, pH and product yield were analysed. Analysis of variance revealed that humidity of inlet air influenced significantly on product yield, moisture content, water activity. Besides, the quality of product in term of ascorbic acid content was affected significantly by drying temperature and fraction of maltodextrin. Higher drying temperatures lead to lesser of ascorbic acid content and the more fraction of maltodextrin used in feed, the more ascorbic acid content retained in product.

1 Introduction

In food industry, drying process is widely used for preservation of foods and shelf life stability. Dried powder by spray drying method has the benefit of good reconstitution, low water activity and moisture content that good for transport and storage [1]. However, stickiness on the drying chamber wall is one of the problem occurred in spray drying step. Fruit juices such as orange juice contain highly hygroscopic ingredients such as fructose, glucose and organic acids which have the low glass transition temperature that lead to stickiness problem in spray drying chamber [2]. Feed solution can be successfully dried with improvement of spray drying condition. This research aims to investigate the effect of inlet air humidity, drying temperature and feed composition on the properties of orange juice spray dried powder. Full factorial design was set to find the optimal spray drying conditions for high quality powders and production yields.

2 Materials and Methods

2.1 Materials

In this study, Concentrated orange juice with a total solids mass concentration of 65.0±0.2%, containing 3.0±0.2% Acid (as citric acid monohydrate), obtained from a local manufacturer, was used. maltodextrin with DE 10-12 (Maxway, Thailand)

2.2 Feed preparation

Orange juice concentrate of 65°Brix concentration was adjusted with maltodextrin (DE10-12) and water, in order to make the constant feed concentration of 40°Brix with the various mass ratio of Orange juice solid content to maltodextrin solution 1:3 and 1:4.5, respectively.

2.3 Spray drying and experiment design

2.3.1 Spray drying

Feed solution was dried by using a co-current spray dryer (JCM Minilab SDE-10, Thailand). The height of the spray dryer are 1.2 m. A n atomiser is two fluid nozzle type. The atomiser air pressure was set at 0.1 MPa using a peristaltic pump for conveying the liquid feed to the chamber. Temperature of drying air was set by using electrical heater. Drying air flow rate was set constantly at 108 m³/h. Humidity of inlet air was controlled by using a dehumidified unit which coupled with a conventional spray dryer as shown in Fig.1.

2.3.2 Experiment design

Experiments were planned applying a full factorial design.
2.4 Powder analysis

2.4.1 Production yield

The production yield was expressed as a percentage of the mass of orange juice spray dried powder gathered at the collection product bottle compare to the solid contents of orange juice solution and maltodextrin solution.

2.4.2 Moisture content and water activity (aw)

The moisture content of orange juice powder was evaluated by vacuum oven method (MMM, VACUCELL model) [3]. Drying period was set at 70°C for 24 hours.

Water activity of the orange juice powder was determined using a water activity meter (an AquaLab 3TE Decagon, USA). The temperature was kept at 25.0±0.1°C during testing.

2.4.3 pH measurement

The pH values of orange juice solutions were analysed by using a pH metre (Consort CR30, Belgium).

2.4.4 Ascorbic acid content

Ascorbic acid content was determined using the titration method modified from Kingwatee et al. (2015) [4]. In this context, spray dried orange powder was reconstituted to concentration of 40 °Brix and then 10 ml aliquot was put into a volumetric flask and 90 ml of 0.4% (w/v) oxalic acid were added. Solution of 0.025%(w/v) 2,6-dichlorophenolindo phenol was used as a titrant. The end point of titration was a stable development of pink colour. L-ascorbic acid was used for construction a standard curve.

2.4.5 Particle morphology

Particle morphology was evaluated by scanning electron microscopy (SEM) ZEISS model EVO MA 10 at Instrument center of Advanced Manufacturing Innovation College, KMITL.

2.4.6 Statistical analysis

The experimental data were evaluated by using ANOVA (Minitab 16 software). The spray drying runs were carried out in duplicate and powder properties analysis were tested in triplicate. All data were reported as mean ± standard deviation.

3 Results and Discussions

Spray drying experiments were run by setting 2 levels of inlet air humidity, 2 levels of feed concentration with the different ration of orange solid content to maltodextrin at the constant feed concentrations of 40 °Brix and a range of inlet drying air temperature (140, 160 and 180°C). This experiments were used a constant feed concentration of 40°Brix to control the amount of water evaporation. Humidity of drying air were set at 10 g/kg dry air and 20 g/kg dry air controlled by using the dehumidified system as shown in Fig. 1. The average humidity of drying air in this experiment was 10.42±0.24 g/kg dry air when using the modified spray dryer and was 19.07±1.55 g/kg dry air when using a conventional spray dryer. The effects of orange juice solid content ratio and different humidity and drying air temperature on the production yield, moisture content, water activity, pH and ascorbic acid content of spray dried product and ANOVA tests are shown in Table 1.

Production yield

The production yield from a range of humidity, mass content ratios and drying temperatures studied was shown in Fig. 2. The resulting yields from these experiments were about 24-64%. In comparison with the yield from a small-scale spray dryer, this should be more than 60% to be acceptable [5]. Only products from using low humidity drying air showed an acceptable production yield. Fig.2 shows an increasing yield from spray drying as the humidity of drying air decrease and illustrates an increase of the yield as the drying temperatures increase. ANOVA tests suggested that both the humidity and drying temperature affected the yield from spray drying significantly (Table 1).
As the humidity of drying air decreased the yield was increased. This was caused by the drier air promoted a drying rate which improved the drying process by decreasing the stickiness problem [6]. As the drying temperature increased the yield was increased. This was caused by the lower moisture content of the powder at higher temperature, which reduced the high deposition of wet particles on the spray dryer walls [5]. However, for the sugar-rich feed spray drying, Goula and Adamopoulos (2010) reported that the production yield is largely affected by the inlet air temperature and the wall depositions increase by increasing the inlet air temperature [6].

Moisture content and water activity of orange juice powder

Spray dried Orange juice powders obtained from the experiments had moisture content in the range of 0.5-2.9% (wb) as shown in Table 1. Fig.3 shows a decrease of moisture content as the drying temperature was increased. High air inlet drying temperature increased the greater water evaporation, due to the higher rate of heat transfer to particles. ANOVA tests suggested that humidity and temperature of drying air temperature affect the moisture content and water activity of product significantly (Table 1). All of moisture content values obtained through this study were under the common observed value in industrial spray drying, which is lower than 5% [7]. Water activity is one of the most importance quality aspects for product storage and stability. The average water activity values of between 0.28 and 0.40, which considered as microbiology safe and oxidative stable [8].

pH and Ascorbic acid content of orange juice powder

The values of pH of the orange juice powders in this study were significantly affected by humidity and drying air temperature included the fraction of orange juice solid content to maltodextrin content (p>0.05). The pH values of the orange juice feed solution were 2.79 ± 0.01 for the O:M of 1:3 and the values of 2.81 ± 0.01 for the O:M of 1:4.5.

### Table 1. Properties of orange juice powder under various conditions

| Humidity (g/kg dry air) | Conc. (O : M) | Inlet temp. (°C) | Production yield (%) | Moisture content (%wb) | Water activity | pH* | Ascorbic acid (mg/g powder) |
|------------------------|--------------|------------------|----------------------|------------------------|---------------|-----|---------------------------|
| 10                     | 1:3          | 140              | 1.59±0.01          | 0.37±0.01              | 3.05±0.02     | 2.94±0.04       |
|                        |              | 160              | 0.81±0.00          | 0.33±0.00              | 3.07±0.03     | 2.73±0.08       |
|                        |              | 180              | 0.55±0.20          | 0.31±0.01              | 3.08±0.01     | 1.47±0.04       |
| 1:4.5                  | 140          | 2.83±0.04        | 0.40±0.00          | 3.05±0.00              | 2.50±0.10     |
|                        | 160          | 1.78±0.07        | 0.32±0.01          | 3.06±0.00              | 2.39±0.06     |
|                        | 180          | 0.98±0.19        | 0.28±0.01          | 3.07±0.01              | 1.96±0.11     |
| 20                     | 1:3          | 24.95±2.41       | 0.39±0.02          | 3.06±0.01              | 2.63±0.04     |
|                        |              | 160              | 1.43±0.05          | 0.33±0.02              | 3.07±0.00     | 2.15±0.04       |
|                        |              | 180              | 0.85±0.52          | 0.33±0.00              | 3.10±0.00     | 1.82±0.08       |
| 1:4.5                  | 140          | 2.93±0.29        | 0.40±0.00          | 3.06±0.03              | 2.39±0.11     |
|                        | 160          | 2.62±0.56        | 0.39±0.01          | 3.08±0.02              | 2.23±0.11     |
|                        | 180          | 1.46±0.36        | 0.28±0.04          | 3.09±0.01              | 1.99±0.19     |

* no significant difference (p>0.05). The different of superscript in the same column means significant difference (p<0.05)
The pH values of the spray dried powder (3.05-3.10) were slightly higher than pH values of feed which means that the acidity of orange juice product was decreased by the spray drying process. As well as the ascorbic acid content was affected significantly by drying temperature and the content of maltodextrin as drying aid. Ascorbic acid content in feed solution was 4.85 mg/g feed solid for the O:M of 1:3 and was 3.39 mg/g feed solid for the O:M of 1:4.5. The contents of ascorbic acid in products are shown in Table 1. The results show that ascorbic acid contents are decreased as the temperature increased because of a degradation of ascorbic acid by temperature during spray drying process [9]. The comparison between ascorbic acid content before and after the drying process can be shown as percentage of retention displayed in Fig.4. The results show that maltodextrin plays the role of ascorbic acid protection as the more maltodextrin contained in feed, the more ascorbic acid content retained in products.

Powder morphology

The morphology of some spray dried orange juice powder was observed. Fig. 5 exhibits SEM image of powder illustrated various irregular sizes of irregularly spherical particles with some smooth surface, some shrinkage and indentation which are one of the typical characteristics of particle formation during spray drying. Walton and Mumford (1999) reported that a hollow particle which collapsed and shrivelled, was formed during drying with the particle inflation from bubble nucleation [10].

4 Conclusions

The influence of spray drying conditions on the qualities of orange juice powder was examined. Production yield, moisture content and water activity were significantly affected by humidity and inlet drying temperature in this study. The using of low humidity drying air shows the greater production yield. In addition, the ascorbic acid content was significantly affected by maltodextrin concentration and drying temperature. Higher concentration of maltodextrin promotes the ascorbic acid retained in orange juice particles. However, higher drying temperatures lead to lesser of ascorbic acid content.
