Abstract: The main purpose of this paper is to analyze the influence of different types of alignment errors on the meshing performance of loaded straight bevel gears. Based on 3D finite element models of the specific loaded assembling straight bevel gear pair, the contact area, transmission error, vibration and noise for the specific loaded straight bevel gear are investigated. The results show that the alignment errors have different degrees of adverse effects on the contact area and the contact line of the straight bevel gear pair, which can affect the transmission error, vibration, and noise of the straight bevel gear drives. The results also demonstrate that the most dangerous type of combined alignment errors is \( \Delta P, \Delta G, \Delta E < 0 \) and \( \Delta \gamma \). The results of this research can provide theoretical guidelines for the assembly and modification of straight bevel gears.

Keywords: straight bevel gear; finite element analysis; alignment error; transmission error; vibration and noise

1. Introduction

Straight bevel gears are widely applied in automobile differentials to transmit power and motion between intersecting shafts for advantages such as smooth transmission, high load-carrying capacity, and low noise [1,2]. In practical straight bevel gear drives, due to reasons such as manufacturer errors of supporting bearings and the deformation of the axis of loaded gears, it is difficult to ensure the meshing of straight bevel gear pairs at the theoretical installation location. That is to say, alignment errors always exist on the straight bevel gear drives. However, alignment errors directly affect the meshing performance and transmission quality of straight bevel gear drives, which may decrease the transmission stability and load uniformity to gear drives greatly and increase the vibration and noise of gear drives dramatically. Therefore, it is of great importance to investigate the straight bevel gear’s transmission characteristics and meshing performance with different alignment errors.

In recent years, many studies have been carried out on the meshing and contact of gears with alignment errors. Litvin et al. [3] investigated the path of contact and transmission errors of face-milled formate generated spiral bevel gears with alignment errors. Simon [4,5] and Litvin et al. [6] analyzed the tooth contact of unloaded spiral bevel gears with alignment errors. Tang et al. [7] analyzed alignment error sensitivity and tolerance limit of spiral bevel gears. Xu et al. [8] and Chen [9] investigated the tooth contact area straight bevel gears with location distance error. Litvin et al. [10] and Wang et al. [11] investigated the meshing performance of loaded spiral bevel gears with alignment errors by FEM. Litvin et al. [12] and Simon [13] investigated the influence of shaft alignments on loaded tooth contact in worm gears. Wang [14] obtained the contact area, the change of
helix angle, and the change of normal pressure angle of unloaded straight bevel gear pairs with alignment errors by numerical calculation method. Chen et al. [15] investigated the contact path and transmission errors of unloaded spur face gears with combined alignment errors. On the one hand, the large majority of these studies only investigated the meshing performance of unloaded gears with combined alignment errors, ignoring the influence of load on the meshing performance of gears. On the other hand, the rest of these studies merely investigated the meshing performance of loaded gears with single alignment error, ignoring the influence of combined alignment errors on the meshing performance of gears. However, few scholars have comprehensively investigated the meshing performance of loaded gears, especially loaded straight bevel gears with combined alignment errors which exist on practical straight bevel gear drives. Therefore, it is necessary to develop 3D finite element models of the loaded straight bevel gear pair to analyze its meshing performance with combined alignment errors.

In this paper, 3D finite element models of loaded straight bevel gear pairs with alignment errors are developed under the ANSYS software environment. Based on these 3D finite element models, the influence of different alignment errors on meshing performance, including contact zone, transmission error, vibration, and noise of the specific loaded straight bevel gear drives, is analyzed.

2. Computerized Design of Gear Model

An accurate 3D gear model is the basis for carrying out a finite element analysis of straight bevel gear drives because the gear transmission relies on continuous meshing of high precise conjugate gear teeth. The accurate 3D gear model is established through the software PRO/E. The basic geometrical data of the sample straight bevel gear pair, considered as the study object, is shown in Table 1. In order to obtain a high accuracy of geometrical model, the spherical involute can be represented by Equation (1) [9,16].

\[
\begin{align*}
    x &= l(\sin \varphi \sin \psi + \cos \varphi \cos \psi \cos \theta) \\
    y &= l(-\cos \varphi \sin \psi + \sin \varphi \cos \psi \sin \theta) \\
    z &= l \cos \varphi \cos \theta
\end{align*}
\]

where: \( \sqrt{x^2 + y^2 + z^2} = l \); \( \psi = \varphi \sin \theta \); \( l \) is the initial radius of the gear, namely the outer cone distance; \( \theta \) is the angle of the base cone; \( \varphi \) is the angle between the starting line on the meshing surface and the instantaneous rotary axis, especially \( \varphi \) equals zero at the beginning point of the spherical involute.

### Table 1. Basic geometric data of the example straight bevel gear pair.

| Parameter                     | Driving Pinion | Driven Gear |
|-------------------------------|----------------|-------------|
| Module [mm]                   | 3.7792         | 3.7792      |
| Shaft angle [deg]             | 90             | 90          |
| Number of teeth               | 10             | 14          |
| Pressure angle [deg]          | 22.5           | 22.5        |
| Modification coefficient of height | -0.1812   | -0.1812     |
| Modification coefficient of thickness | 0.05     | -0.05       |
| Addendum coefficient          | 0.8            | 0.8         |
| Headspace coefficient         | 0.188          | 0.188       |
| Face width [mm]               | 9.75           | 9.75        |
| Gear center hole [mm]         | 7.0275         | 10          |

The alveolar surface is established by the spherical involute equation and the basic geometrical data of the sample straight bevel gear, and the alveolar entity is constructed by solidifying, as shown in Figure 1. The gear hub and cogging are imported into the assembly environment and the gear hub is cut by the cogging, as shown in Figure 2. Through rotation copying the tooth spaces, the full gear geometry model is accomplished. Figure 3 shows an assembly of two full 3D straight bevel gears’ geometry.
3. Establishment of Finite Element Models

The finite element model of a straight bevel gear pair is performed with Solid45 (8-node isoparametric hexahedron element). The material is 40 Cr steel with the properties of Young’s modulus $E = 2.1 \times 10^5$ MPa and Poisson’s ratio $\mu = 0.3$. The friction coefficient between two gears is 0.2 and the applied torque $T = 50$ Nm.

The developed approach for the finite element models is established as follows:

Step 1: The 3D geometrical models with the format of IGES are imported into ANSYS. Each tooth is divided into five subvolumes by auxiliary intermediate surfaces, as shown in Figure 4.
Step 2: In the three gear teeth in contact analysis, there are 30 elements in profile direction and 20 elements in longitudinal direction. In the other gear teeth, there are only 5 elements in profile direction and 20 elements in longitudinal direction, as shown in Figure 5.

![Mesh-dividing model of meshing tooth pairs.](image)

**Figure 5.** Mesh-dividing model of meshing tooth pairs.

Step 3: Setting contact pairs for the gears. Contact pairs (a contact pair consists of a target surface and a contact surface) are defined in the contact position. Generally, the surface which has larger curvature will be chosen as the contact surface, thus the tooth surface of the pinion is picked as the contact surface and the tooth surface of the gear is defined as the target surface. In Figure 6, two contact pairs are shown when two pairs of teeth are in contact at the same time. By deleting or adding a contact pair, the simulation of single-tooth pair meshing or multi-tooth pairs meshing can be achieved.

![Definition of contact pairs when two tooth pairs are in contact.](image)

**Figure 6.** Definition of contact pairs when two tooth pairs are in contact.

Step 4: Setting of boundary conditions and loads is achieved in the two local cylindrical coordinate systems, as shown in Figure 7. The following ideas are approved:

(i) Nodes on the bottom rim of the driven gear are fixed.

(ii) For the nodes on the bottom rim of the driving pinion, the radial and axial degrees of freedom are considered as fixed, and only the rational degree of freedom is set as free and coupled.

(iii) The effect of force $F$ at every node on the bottom rim of the driving pinion in the rotational direction on the pinion is equal to that of working torque $T$ on the pinion. The force $F$ is defined as the following:

$$ F = \frac{T}{n \times r_d} $$

where: the applied torque $T = 50$ Nm; $n = 2100$ is the number of nodes on the bottom rim of the driving pinion; $r_d = 7.0275$ mm is the radius of the bottom rim of the driving pinion.
Figure 7. The boundary conditions and loads of the driving pinion and the driven gear.

Step 5: The simulation in the whole meshing cycle can be achieved through rotating the straight bevel gears.

4. Determination of the Meshing Interval for Investigation

The basic meshing characteristic of loaded straight bevel gear drives is the periodical change of the meshing tooth pairs, as shown in Figure 8. In Figure 8, three pairs of teeth, named tooth pair −1, 0, +1, respectively, are defined to describe the meshing process. At the beginning, tooth pair −1 bears all load in the single pair tooth contact zone I. When reaching the transferring point $P_1$, tooth pair 0 enters mesh so that the total load is shared by both tooth pair −1 and tooth pair 0 in the double pair tooth contact zone II. When transferring point $P_2$ is reached, tooth pair −1 exits out of mesh. At the same time, the total load is suddenly transmitted to tooth pair 0 and the single pair tooth contact zone I for tooth pair 0 begins. As with the cycle, the load and motion will be transmitted from tooth pair 0 to tooth pair +1.

Figure 8. Illustration of gear mesh.

As a result, a whole meshing cycle contains a single pair tooth contact zone I and a double pair tooth contact zone II. In this paper, a whole meshing cycle (A and B in Figure 8) is chosen for investigation. The transferring points $P_1$ and $P_3$ are selected as the critical points at the beginning and the end of a meshing cycle in the analysis, respectively.
5. Selection of Alignment Errors

As shown in Figure 9, four basic types of alignment errors can be defined as follows:

(i) \( \Delta \gamma \) is defined as the change of crossing angle.
(ii) \( \Delta P \) is defined as the axial displacement of the pinion.
(iii) \( \Delta G \) is defined as the axial displacement of the gear.
(iv) \( \Delta E \) is defined as the change center distance of the assembling straight bevel gears.

Figure 9. Illustration of alignment errors.

The values of alignment errors are shown in Tables 2 and 3. The principles of choosing the values of alignment errors are as follows: when the value of alignment errors is less than zero, the large negative value will cause the occurrence of tooth surface interference. Therefore, the negative values of alignment errors should not be too large. When the value of alignment errors is larger than zero, the large positive value will make the contact ratio of the gear decrease greatly. Especially when \( \Delta G = 0.1 \) or \( \Delta P = 0.1 \), ends engaging between the teeth of straight bevel gears will occur, which causes contact stress on tooth surfaces to increase significantly. Furthermore, there are combined alignment errors existing in the practical assembly of gears which will produce greater influence on the meshing performance of the straight bevel gear pair. Therefore, we chose the values of alignment errors in Tables 2 and 3 to discuss the influence of alignment errors on the gear drives. When the gears are in standard installation, the values of alignment errors are zero.

Table 2. The values of single alignment error.

| Basic Type of Alignment Error | \( \Delta \gamma \) (deg) | \( \Delta P \) (mm) | \( \Delta G \) (mm) | \( \Delta E \) (mm) |
|------------------------------|--------------------------|---------------------|---------------------|---------------------|
| Value                        | \(-0.01\)                | \(-0.01\)           | \(-0.01\)           | \(-0.02\)           |
|                              | 0.1                      | 0.01                | 0.01                | \(-0.01\)           |
|                              | 0.2                      | 0.05                | 0.05                | 0.01                |
|                              | 0.5                      | 0.1                 | 0.1                 | 0.02                |
|                              | 1                        |                      |                     |                     |
Table 3. The values of combined alignment errors.

| Combined Alignment Errors | $\Delta P\Delta G\Delta \gamma$ | $\Delta P\Delta \gamma\Delta \gamma$ | $\Delta P\gamma\Delta \gamma$ | $\Delta P\gamma\Delta E$ | $\Delta P\gamma\Delta E\Delta \gamma$ |
|---------------------------|-------------------------------|----------------------------------|-------------------------------|-------------------------|----------------------------------|
| Value                     | 0.1 0.1                       | 0.1 $-0.02$                      | 0.1 $-0.02$                   | 0.1 0.1                 | 0.1 0.1 $-0.02$ 0.5              |
|                           | 0.1 0.1 0.5                   | 0.1 0.02                         | 0.1 0.02                      | 0.1 0.1                 | 0.1 $-0.02$ 0.5 0.1 0.02          |
|                           | 0.1 $-0.02$ 0.5               | 0.1 $-0.02$ 0.5                  | 0.1 0.02                      | 0.1 0.1                 | 0.1 0.02 0.5                     |
|                           | 0.1 0.02 0.5                  | 0.1 0.02                         | 0.1 0.02                      | 0.1 0.1                 | 0.1 0.02 0.5                     |

6. Results and Discussion

6.1. Influence of Single Alignment Error on the Gear Mesh

6.1.1. Influence of Single Alignment Error on the Contact Area

In this paper, the contact area of the working tooth pair at the pitch cone is investigated. Figure 10 presents the distribution of contact stress on the tooth surface for the straight bevel gears with the different single alignment error. As shown in Figure 10a, the contact stress along the longitudinal direction of the contact tooth pair is linear when the gears are in standard installation. Furthermore, contact stress is higher at the heel of the tooth. In Figure 10b, when $\Delta P = 0.1$, the contact position moves to the heel of the tooth and the length of contact line along the longitudinal direction decreases. From Figure 10c, it can be seen that the contact position moves to the heel of the tooth and the length of contact line decreases when $\Delta G = 0.1$. By comparing Figure 10d with Figure 10e, it can be seen that the contact position moves to the heel of the tooth when $\Delta E = -0.02$ and it moves to the toe of the tooth when $\Delta E = 0.02$. Moreover, the length of contact line decreases when $\Delta E = -0.02$ or $\Delta E = 0.02$. As shown in Figure 10f, when $\Delta \gamma = 0.5$, the contact area of the tooth pair is basically the same as that in the standard installation. Therefore, it can be concluded that the length of contact line decreases under the single alignment error $\Delta P$, $\Delta G$, and $\Delta E$, and the contact area of the tooth pair is not sensitive to the alignment error $\Delta \gamma$.

6.1.2. Influence of the Single Alignment Error on the Transmission Error

The transmission error is the difference between the angle displacement of gears in reality and that in theory. Since the nodes on the bottom rim of the driven gear are fixed and the rational degree of freedom of the nodes on the bottom rim of the driving pinion is set as free, so the angle displacement of the bottom rim of the driven gear is zero. Therefore, the angle displacement of the bottom rim of the pinion is used to represent the transmission error in this paper. The angle displacement of the bottom rim of the pinion can be calculated using Equation (3) [17]:

$$\Delta \phi_1 = \delta / r_d$$  \hspace{1cm} (3)

where: $\delta$ is the circumferential displacement of the nodes on the bottom rim of the pinion under load, $r_d$ is the radius of the bottom rim of the pinion, and $\phi_1$ is the rotation angle of the driving pinion.

Figures 11–14 show the variation of transmission errors in the meshing cycle with four basic types of alignment errors. It can be seen from Figures 11 and 12 that the transmission error gradually increases with the increasing of $\Delta P$ or $\Delta G$ in the meshing cycle. This is because the length of contact line gradually decreases with the increasing of $\Delta P$ or $\Delta G$, as shown in Figure 10b,c, respectively. It can be also seen from Figures 11 and 12 that $\Delta P$ has a more significant effect on the transmission error at the transferring point $P_3$ and $\Delta G$ has a more significant effect on the transmission error at the transferring point $P_2$.

From Figure 13, it can be seen that the transmission errors increase with the increasing of $\Delta E$. Furthermore, the influence of $\Delta E > 0$ on the transmission error is larger than that, when $\Delta E < 0$. The main reason for this is that, when $\Delta E > 0$, the stress concentration at the toe is more serious than that at the heel of the straight bevel gear tooth, when $\Delta E < 0$, as shown in Figure 10d,e, respectively.

It can be seen from Figure 14 that the transmission errors increase slowly with the increasing of $\Delta \gamma$, i.e., the transmission error is not sensitive to $\Delta \gamma$. The main reason for this is that the length of contact line decreases slowly with the increasing of $\Delta \gamma$, as shown in Figure 10f.
In short, the transmission error is sensitive to the single alignment error \( \Delta P \), \( \Delta G \), and \( \Delta E \). Therefore, the single alignment error \( \Delta P \), \( \Delta G \), and \( \Delta E \) should be controlled in the practical assembly of straight bevel gears to ensure the straight bevel gear pair meshing smoothly.

**Figure 10.** Distribution of contact stress on tooth surface for the pinion (top) and the gear (bottom) with the different single alignment error. (a) \( \Delta P = 0 \), (b) \( \Delta P = 0.1 \), (c) \( \Delta G = 0.1 \), (d) \( \Delta E = -0.02 \), (e) \( \Delta E = 0.02 \), (f) \( \Delta \gamma = 0.5 \).
This is because the length of contact line gradually decreases with the increasing of $\Delta P$ or $\Delta G$, as shown in Figure 10b,c, respectively. It can be also seen from Figures 11 and 12 that $\Delta P$ has a more significant effect on the transmission error at the transferring point $P_3$ and $\Delta G$ has a more significant effect on the transmission error at the transferring point $P_2$.

**Figure 11.** Variation of transmission error in the meshing cycle with different $\Delta P$.

From Figure 13, it can be seen that the transmission errors increase with the increasing of $\Delta E$. Furthermore, the influence of $\Delta E > 0$ on the transmission error is larger than that, when $\Delta E < 0$. The main reason for this is that, when $\Delta E > 0$, the stress concentration at the toe is more serious than that at the heel of the straight bevel gear tooth, when $\Delta E < 0$, as shown in Figure 10d,e, respectively.
6.1.3. Influence of Single Alignment Error on the Vibration and Noise of Gear Drives

In this paper, the maximum fluctuation of transmission errors (MFTE) of the gear pair is used to assess the vibration level of gear drives, as shown in Figure 15. The higher the MFTE of the gear pair, the more dramatic the vibration of gear drives. Meanwhile, Equation (4) [10] is used to evaluate the relative size of noise of gear drives with different types of alignment errors qualitatively.

\[
\frac{\omega_{(e)}^2 \text{rms}}{\omega_{(0)}^2 \text{rms}} = \frac{\sum_{i=2}^n [(\Delta \phi_{1(e)})_i - (\Delta \phi_{1(e)})_{i-1}]^2}{\sum_{i=2}^n [(\Delta \phi_{1(0)})_i - (\Delta \phi_{1(0)})_{i-1}]^2}
\]  

(4)
where: $\omega_{2(0)\text{rms}}^2$ is the root mean square of the signals (in rms) caused by the transmission errors with some kind of alignment error, while $\omega_{0\text{rms}}^2$ is the root mean square of the signals (in rms) caused by the transmission errors under standard installation; $(\Delta \Phi_{1i(0)})_{i}$ is the value of transmission error at the engagement position $i$ with some kind of alignment error; $(\Delta \Phi_{1i(0)})_{i}$ is the value of transmission error at the engagement position $i$ under standard installation; engagement position $i$ and engagement position $i - 1$ are two successive engagement positions.

\[
\Delta P, \Delta G, \Delta E, \Delta \gamma
\]

Figure 15. Variation of transmission error in the meshing cycle under standard installation.

Figure 16 presents the variation of MFTE of straight bevel gear drives with different alignment errors. From Figure 16, it can be seen that MFTE increases dramatically with the increasing of $\Delta P$, $\Delta G$, and $\Delta E$ ($\Delta E < 0$), but it increases slowly with the increasing of $\Delta E$ ($\Delta E < 0$). It can be also seen from Figure 16 that MFTE increases slowly, when $0 < \Delta \gamma < 0.1$ or $\Delta \gamma > 0.2$, but it increases sharply, when $0.1 < \Delta \gamma < 0.2$. Therefore, it can be concluded that the alignment errors $\Delta P$, $\Delta G$, $\Delta E$ ($\Delta E < 0$), and $\Delta \gamma$ have great influence on MFTE. That is to say, the vibration of straight bevel gear drives is sensitive to the four basic types of alignment errors.

Figure 16. Variation of MFTE with different alignment errors.
Figure 17 presents the variation of noise of straight bevel gear drives with different alignment errors. As shown in Figure 17, it can be concluded that the variation of noise of gear drives is basically in accordance with the variation of MFTE of gear drives with different alignment errors. The noise of straight bevel gear drives is sensitive to the four basic types of alignment errors $\Delta P$, $\Delta G$, $\Delta E$ ($\Delta E < 0$), and $\Delta \gamma$. Therefore, it is important to control the alignment errors $\Delta P$, $\Delta G$, $\Delta E$ ($\Delta E < 0$), and $\Delta \gamma$ in the practical assembly of straight bevel gears to weaken the vibration and noise of the straight bevel gear drives.

![Figure 17. Variation of noise of gear drives with different alignment errors.](image)

6.2. Influence of Combined Alignment Errors on the Gear Mesh

6.2.1. Influence of Combined Alignment Errors on the Contact Zone

Figures 18 and 19 show the distribution of contact stress on the tooth surface for the straight bevel gears with combined alignment errors. As shown in Figure 18a,e,g, it can be seen that the length of contact line along the longitudinal direction decreases significantly and the contact stress concentrates on each heel of the pinion tooth and the gear tooth, when $\Delta P = 0.1$ and $\Delta G = 0.1$, $\Delta P = 0.1$ and $\Delta E = -0.02$, $\Delta G = 0.1$ and $\Delta E = -0.02$. Therefore, the gear transmission will be less smooth when those combined alignment errors exist. As shown in Figure 18b,c,h,i, it can be seen that, when $\Delta \gamma$ and one of $\Delta P$, $\Delta G$, $\Delta E$ combines, the teeth contact zone has little change compared with that in the single $\Delta P$, $\Delta G$, $\Delta E$. By comparing Figure 18d,f with Figure 10b,c, it can be seen that the length of contact line along the longitudinal direction increases, when $\Delta P = 0.1$ and $\Delta E = 0.02$ or $\Delta G = 0.1$ and $\Delta E = 0.02$, which will make the transmission of straight bevel gears smooth.

By comparing Figure 19a,b with Figure 18a, it can be seen that the length of contact line along the longitudinal direction decreases dramatically when $\Delta P = 0.1$, $\Delta G = 0.1$, and $\Delta E = -0.02$ compared with when $\Delta P = 0.1$ and $\Delta G = 0.1$. However, the length of contact line along the longitudinal direction increases when $\Delta P = 0.1$, $\Delta G = 0.1$, and $\Delta E = 0.02$ compared with when $\Delta P = 0.1$ and $\Delta G = 0.1$. Lastly, it can be seen from Figure 19i that the most dangerous type of alignment errors is when $\Delta P$, $\Delta G$, $\Delta E < 0$, and $\Delta \gamma$, because the length of contact line along the longitudinal direction decreases dramatically. By comparing Figures 18 and 19 with Figure 10, it can be concluded that the alignment errors have a cumulative effect on the length of contact line. Furthermore, it has proven that the contact zone is not sensitive to the alignment error $\Delta \gamma$ again from Figures 18a,d–g and 19c–g with Figure 10.
Figure 18. Distribution of contact stress on tooth surface for the pinion (top) and the gear (bottom) with combined alignment errors. (a) $\Delta P = 0.1$ and $\Delta G = 0.1$, (b) $\Delta \gamma = 0.5$ and $\Delta G = 0.1$, (c) $\Delta \gamma = 0.5$ and $\Delta P = 0.1$, (d) $\Delta G = 0.1$ and $\Delta E = 0.02$, (e) $\Delta G = 0.1$ and $\Delta E = -0.02$, (f) $\Delta P = 0.1$ and $\Delta E = 0.02$, (g) $\Delta P = 0.1$ and $\Delta E = -0.02$, (h) $\Delta \gamma = 0.5$ and $\Delta E = 0.02$, (i) $\Delta \gamma = 0.5$ and $\Delta E = -0.02$. 

Therefore, the gear transmission will be less smooth when those combined alignment errors. (g) and 19c–g with Figure 10.

6.2.2. Influence of Combined Alignment Errors on the Transmission Error

The transmission errors of the gear drive in the meshing cycle with combined alignment errors are presented in Figure 20. The results of the investigation are as follows:

1. As shown in Figure 20a, it can be seen that, when $\Delta P$ and $\Delta G$ combine, the transmission error increases greatly in the whole meshing circle, compared with that in the single $\Delta P$ or $\Delta G$.

2. As shown in Figure 20b, it can be seen that, when $\Delta P$ and $\Delta E$ ($\Delta E < 0$) combine, the transmission error increases greatly in the whole meshing circle compared with that in the single $\Delta P$. However, when $\Delta P$ and $\Delta E$ ($\Delta E > 0$) combine, the transmission error decreases dramatically in the single pair tooth contact zone, compared with that in the single $\Delta P$. However, the transmission error in the double pair tooth contact zone is basically in accordance with the single $\Delta P$.

3. As shown in Figure 20c, it can be obtained that, when $\Delta G$ and $\Delta E < 0$ combine transmission error increases greatly in the whole meshing circle compared with that in single $\Delta G$. However, when $\Delta G$ and $\Delta E > 0$ combine, the transmission error decreases dramatically in the whole meshing circle compared with that in single $\Delta G$.

4. As shown in Figure 20d,e,f, it can be seen that, when $\Delta \gamma$ and one of $\Delta P$, $\Delta G$, $\Delta E$ combines, the transmission errors are basically consistent compared with that in single $\Delta P$, $\Delta G$ or $\Delta E$. Therefore, it can be concluded that the transmission error is not sensitive to $\Delta \gamma$.

5. It can be seen from Figure 20 that it is the most dangerous type of alignment errors for increasing the transmission error dramatically, when $\Delta P$, $\Delta G$, $\Delta E$ ($\Delta E < 0$) and $\Delta \gamma$.

6. The alignment errors have a cumulative effect on the length of contact line and the contact zone causing the change of gear stiffness. The reduction of the length of contact line will cause the decrease of gear stiffness. The transmission errors increase with the decreasing of gear stiffness.

6.2.3. Influence of Combined Alignment Errors on the Vibration and Noise of Gear Drives

Figures 21–24 present the vibration and noise of gear drives with combined alignment errors. As shown in Figure 21, it can be seen that the vibration and noise of gear drives with $\Delta P$ and $\Delta G$ decreases greatly compared with that with single $\Delta P$ or $\Delta G$. Comparing Figure 18a with Figure 20a, it can be seen that, when $\Delta P$ and $\Delta G$ combine, the transmission error increases more in the double pair tooth contact zone, resulting in the reduction of the fluctuation of transmission error at the transferring point $P_2$, and the reduction of the fluctuation of transmission error at the transferring point $P_2$ leads to the decrease of the vibration and noise of gear drives.

From Figure 22, it can be seen that the changing trend of vibration and noise of gear drives with $\Delta P$, $\Delta E$, and $\Delta \gamma$ is approximately consistent. Furthermore, the vibration and noise of gear drives with $\Delta P$ and $\Delta E$ ($\Delta E > 0$) decreases dramatically, because the increase of the length of contact line along the longitudinal direction results in the increase of gear stiffness. As shown in Figure 23, it can be seen that the changing trend of vibration and noise of gear drives with $\Delta G$, $\Delta E$, and $\Delta \gamma$ is basically consistent. Furthermore, the vibration and noise of gear drives with $\Delta G$, $\Delta E$, and $\Delta \gamma$ decrease slightly compared with that with single $\Delta G$.

As shown in Figure 24, it can be seen that the changing trend of vibration and noise of gear drives with $\Delta E$ and $\Delta \gamma$ is almost consistent. Furthermore, the vibration of gear drives increases slightly, but the noise of gear drives with $\Delta E$ ($\Delta E < 0$) and $\Delta \gamma$ increases dramatically compared with that with single $\Delta E$ ($\Delta E < 0$). From Figures 21–24, it can be concluded that the most dangerous type of alignment errors for increasing the vibration and noise of gear drives dramatically is when $\Delta P$, $\Delta G$, $\Delta E$ ($\Delta E < 0$), and $\Delta \gamma$. 
(4) As shown in Figure 20d,e,f, it can be seen that, when Δγ and one of ΔP, ΔG, ΔE combines, the transmission errors are basically consistent compared with that in single ΔP, ΔG or ΔE. Therefore, it can be concluded that the transmission error is not sensitive to Δγ.

(5) It can be seen from Figure 20 that it is the most dangerous type of alignment errors for increasing the transmission error dramatically, when ΔP, ΔG, ΔE (ΔE < 0) and Δγ.

(6) The alignment errors have a cumulative effect on the length of contact line and the contact zone causing the change of gear stiffness. The reduction of the length of contact line will cause the decrease of gear stiffness. The transmission errors increase with the decreasing of gear stiffness.

6.2.3. Influence of Combined Alignment Errors on the Vibration and Noise of Gear Drives

Figures 21–24 present the vibration and noise of gear drives with combined alignment errors. As shown in Figure 21, it can be seen that the vibration and noise of gear drives with $\Delta P$ and $\Delta G$ decreases greatly compared with that with single $\Delta P$ or $\Delta G$.

Comparing Figure 18a with Figure 20a, it can be seen that, when $\Delta P$ and $\Delta G$ combine, the transmission error increases more in the double pair tooth contact zone, resulting in the reduction of the fluctuation of transmission error at the transferring point $P_2$, and the reduction of the fluctuation of transmission error at the transferring point $P_2$ leads to the decrease of the vibration and noise of gear drives.
Furthermore, the vibration and noise of gear drives with increase of gear stiffness. As shown in Figure 23, it can be seen that the changing trend of vibration and noise of gear drives with increase of the length of contact line along the longitudinal direction results in the noise of gear drives with alignment errors based on $ΔP$, $ΔE$, and $Δγ$, respectively.

The most dangerous type of alignment error is

Since the combined alignment errors have great influence on the meshing perfor-

The alignment errors will cause the straight bevel gear pair contacting at one end and

gaping at the other end of the teeth and make the contact zone and the contact line
of the straight bevel gear pair change greatly. Furthermore, this change has a direct
effect on the transmission error, vibration, and noise of the drives.

The contact zone and the contact line of the straight bevel gear pair are sensitive to

ΔP, ΔG, and ΔE, resulting in the uneven load distribution and stress concentration on
the tooth pair. However, the contact zone and the contact line of the straight bevel
gear pair are not sensitive to the alignment error Δγ.

The single alignment error ΔP, ΔG or ΔE has great influence on the transmission error,

vibration, and noise of the straight bevel gear drives, and the single alignment error
Δγ has great influence on the vibration and noise of the straight bevel gear drives,
but it does not have a great effect on the transmission error of the straight bevel gear

Since the combined alignment errors have great influence on the meshing performance of the straight bevel gear, it is important to control the combined alignment errors to ensure the straight bevel gear drives with low vibration and noise. In the practical assembly of the straight bevel gear pair, it is feasible to improve the meshing performance of the straight bevel gear through a better combination of the alignment errors such as the combination of ΔP and ΔE (ΔE > 0) or the combination of ΔG and ΔE (ΔE > 0).

The most dangerous type of alignment error is ΔP, ΔG, ΔE (ΔE < 0) and Δγ. Under
