Abstract

Background: mTOR signaling pathway and its downstream serine/threonine kinase p70S6K were frequently activated in human cancers. The dysregulation of the mTOR pathway has been found to be a contributing factor of a variety of different cancer. To investigate the role of mTOR signal pathway in the stepwise development of gastric carcinomas, we analyzed the correlations between the mTOR and P70S6K expression and clinic pathological factors and studied its prognostic role in gastric carcinomas.

Methods: mTOR and phospho-p70S6K proteins were examined by immunohistochemistry on tissue microarray containing gastric carcinomas (n = 412), adenomas (n = 47) and non-neoplastic mucosa (NNM, n = 197) with a comparison of their expression with clinicopathological parameters of carcinomas.

Results: There was no difference of mTOR expression between these three tissues (p > 0.05). Cytoplasmic phospho(p)-P706SK was highly expressed in adenoma, compared with ANNMs (p < 0.05), whereas its nuclear expression was lower in gastric carcinomas than gastric adenoma and ANNMs (p < 0.05). These three markers were preferably expressed in the older patients with gastric cancer and intestinal-type carcinoma (p < 0.05). mTOR expression was positively correlated with the cytoplasmic and nuclear expression of p-P70S6K (p < 0.05). Nuclear P70S6K was inversely linked to tumor size, depth of invasion, lymph node metastasis and UICC staging (p < 0.05). Univariate analysis indicated that expression of mTOR and nuclear p-P70S6K was closely linked to favorable prognosis of the carcinoma patients (p < 0.05). Multivariate analysis showed that age, depth of invasion, lymphatic invasion, lymph node metastasis, Lauren's classification and mTOR expression were independent prognostic factors for overall gastric carcinomas (p < 0.05).

Conclusion: Aberrant expression of p-P70S6K possibly contributes to pathogenesis, growth, invasion and metastasis of gastric carcinomas. It was considered as a promising marker to indicate the aggressive behaviors and prognosis of gastric carcinomas.
**Introduction**

Gastric carcinoma ranks as the world's second leading cause of cancer mortality behind lung cancer despite a sharp worldwide decline in both its incidence and mortality since the second half of the 20th century. It continues to be a major health problem because of the slow decrease in incidence in Asia and high mortality of diagnosed gastric carcinoma in West [1]. Therefore, it is of much significance for the prevention, treatment and prognosis evaluation of gastric cancer to clarify its molecular mechanisms and find out a good biomarker to indicate its carcinogenesis and subsequent progression.

The mammalian target of rapamycin (mTOR) also known as FK506 binding protein 12-rapamycin associated protein 1 is a serine/threonine protein kinase that supports cell growth, cellular metabolism, cell proliferation, cell motility, cell survival, protein synthesis, and transcription such as angiogenesis and autophagy. mTOR that is an evolutionarily conserved serine/threonine kinase of a 289-kDa in length belongs to the phosphoinositide 3-kinase (PI3K)-related kinase family. mTOR is composed of an N-term; 20 tandem repeats-HEAT which are implicated in protein-protein interactions; and a C-term which includes a FAT domain, a FBR domain, a kinase domain, a NDR domain and a FATC domain. The FATC domain is essential to mTOR activity and the deletion of a single amino acid from this domain abrogates the activity. mTOR can be autophosphorylated via its intrinsic serine/threonine kinase activity. mTOR exerts its multiple functions in the context of two different multiprotein complexes: mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2). mTORC1 is composed of mTOR, Raptor, mLST8, and PRAS40, and importantly activates p70 ribosomal protein S6 kinase and inactivates eIF4E binding protein 1, which promotes protein translation and cell growth. Conversely, mTORC2 is composed of mTOR, Rictor, Sin1, and mLST8, phosphorylates and activates another member of the AGC kinase family, Akt. Current research indicates that mTOR integrates the input from multiple upstream pathways, including insulin, growth factors (such as IGF-1 and IGF-2), and mitogens. mTOR also functions as a sensor of cellular nutrient and energy levels and redox status [2-5].

**Materials and methods**

**Subjects**

Gastric carcinomas (n = 421) were collected from the surgical resection, adenoma (n = 45) from endoscopic biopsy or polypectomy, and gastritis (n = 49) from the endoscopic biopsy in Shengjing Hospital of China Medical University and the First Affiliated Hospital of China Medical University between 1993 and 2006. All carcinomas were adenocarcinomas and the adenoma group was free from non-neoplastic polyp types, leiomyomas and benign GIST's. The patients with gastric carcinoma were 293 men and 126 women (29-91 years, mean = 65.4 years). Among them, 156 cases have carcinomas accompanied with lymph node metastasis. None of the patients underwent chemotherapy or radiotherapy before surgery. They all provided consent for use of tumour tissue for clinical research and our University Ethical Committee approved the research protocol. We followed up all patients by consulting their case documents or through telephone.

**Pathology**

All tissues were fixed in 4% neutralised formaldehyde, embedded in paraffin and incised into 4 mm sections. These sections were stained by haematoxylin-and-eosin (HE) to confirm their histological diagnosis and other microscopic characteristics. The staging for each gastric carcinoma was evaluated according to the Union Internationale Contre le Cancer (UICC) system for the extent of tumour spread [12]. Histological architecture of gastric...
carcinoma was expressed in terms of Lauren's classification [13,14]. Furthermore, tumour size, depth of invasion, lymphatic and venous invasion were determined.

**Tissue microarray (TMA)**
Prior to TMA construction, all tissue slides were histopathologically re-evaluated by one pathologist and. Two 2.0-mm tissue cores were taken from representative areas of gastric samples using a manual arraying device (MTA-1; Beecher Inc., Sun Prairie, WI, USA) and mounted in a new recipient block. Four-μm-thick sections were consecutively incised from the recipient block and transferred to poly-lysine-coated glass slides. HE staining was performed on TMA for confirmation of tumor tissue.

**Immunohistochemistry**
For the immunohistochemical procedure, 4-μm-thick sections were deparaffinized with xylene and rehydrated through an alcohol gradient. The sections were quenched with 3% hydrogen peroxide in absolute methanol for 20 min to block endogenous peroxidase activity, and heated in a microwave for 15 min in citrate buffer (0.01 mol/L, pH 6.0) to retrieve the antigen. The sections were incubated with rabbit anti-mTOR antibody (Clone ID: Y392, 1612-1, Epitomics, USA; 1:250) and anti-phospho-p70 s6 kinase (pT389. Clone ID: E175, 1175-1, Epitomics, USA; 1:50) for 60 min, followed by exposure to the anti-rabbit Envison-PO (DAKO, USA) antibody for 60 min. Binding sites were visualized with 3, 3′-diaminobenzidine (DAB) with the 5-min reaction. After each treatment, the slides were washed with TBST (10 mM Tris-HCl, 150 mM NaCl, 0.1% Tween 20) three times for 1 min. After counterstained with Mayer’s haematoxylin, the sections were dehydrated, cleared and mounted. Omission of the primary antibody was used as a negative control. As indicated in Figure 1, mTOR was positively localized in the cytoplasm, whereas P70S6K in the cytoplasm and nucleus. One hundred cells were randomly selected and counted from 5 representative fields of each section blindly by three independent observers. The positive percentage of counted cells was graded semi-quantitatively according to a four-tier scoring system: negative (-), 0~5%; weakly positive (+), 6~25%; moderately positive (++), 26~50%; and strongly positive (+++), 51~100%.

**Statistical Analysis**
Statistical evaluation was performed using Spearman correlation test to analyze the rank data. Kaplan-Meier survival plots were generated and comparisons between survival curves were made with the log-rank statistic. The Cox’s proportional hazards model was employed for mul-

**Figure 1**
**Immunohistochemical staining in gastritis, gastric adenoma and carcinoma.** Note mTOR positivity was strongly observed in the cytoplasm, while P70S6K in the cytoplasm and nucleus. mTOR expression was observed in non-cancerous mucosa (a, +++), adenoma (b, ++++) and carcinoma(c, ++). P70S6K protein was immunoreactive in non-neoplastic mucosa (d, ++), adenoma (e, ++++) and carcinoma (f, +++).
tivariate analysis. p < 0.05 was considered as statistically significant. SPSS 10.0 software was employed to analyze all data.

Results
mTOR and p70 S6 kinase expression in gastric carcinomas
As showed in Figure 1, mTOR was positively immunostained in the cytoplasm of gastric epithelial cells, adenomas and carcinomas. Overall, mTOR expression was detected respectively in 66.3% of NNM (n = 197), 47 out of 67 adenoma patients (70.1%), and 255 out of total 412 gastric carcinoma patients (61.2%). Statistically, there was no significance between these three groups (p > 0.05, Table 1). As summarized in Table 2, cytoplasmic P70S6K was highly expressed in adenoma (53.7%, 37/67), compared with NNM (34.5%, 68/197, p < 0.05). However, nuclear p70S6K expression was positive in 216 cases of 404 gastric carcinomas (59.5%), lower than gastric adenoma (83.6%, 56/67) and ANTMs (78.2%, 154/197, p < 0.05, Table 3).

These three markers were preferably expressed in the older patients with gastric cancer and intestinal-type carcinoma (p < 0.05, Table 4, Table 5 and Table 6). mTOR expression was positively correlated with the cytoplasmic and nuclear expression of P70S6K (p < 0.05, Table 4). mTOR expression was inversely correlated with tumour size, depth of invasion, lymphatic invasion, lymph node metastasis and UICC staging (p < 0.05, but not sex, tumor size, UICC staging, cytoplasmic or nuclear P70S6K expression were independent prognostic factors for overall gastric carcinomas (p > 0.05, Table 7).

Discussion
Mammalian target of rapamycin (mTOR) is also known as FKBP-rapamycin-associated protein or rapamycin and FKBP target and functions as a serine/threonine protein kinase to sense adenosine triphosphate and amino acids to balance nutrient availability and cell growth. When sufficient nutrients are available, mTOR is phosphorylated via the phosphoinositide 3-kinase (PI3K)/AKT signaling pathway, transmits a positive signal to p70 S6 kinase (p70S6K), and participates in the inactivation of the eukaryotic translation initiation factor 4E inhibitor, 4EBP1. Therefore, mTOR plays a key role in cellular growth and homeostasis, and its regulation is frequently altered in tumors [8,15].

Although mTOR protein can shuttle between the nucleus and cytoplasm [16,17], we only observed its cytoplasmic distribution in line with the figure of its antibody data sheet. The phenomenon might be due to cell specificity and different antibody. In the present study, the antibody was produced with a synthetic peptide corresponding to residues near the C-term of PI3K/P44K domain of human mTOR/FRAP as an immunogen. In addition, we found no

difference in mTOR expression between gastric ANTC, adenoma and carcinoma, which suggested its role of growth-regulating in all gastric epithelial and lesion cells. However, its active form, phosphorylated mTOR might contribute to the carcinogenesis according to the literature [18-23]. In contrast, its down-stream target, the aberrant expression of cytoplasmic and nuclear phosphor-P70S6K occurred in gastric adenoma-adenocarcinoma sequence. For instance, adenoma displayed higher cytoplasmic expression of active p70S6K than NNM group, whereas nuclear counterpart was less expressed in carcinoma than NNM and adenoma. It was speculated that different subcellular distribution of phospho-p70S6K might have distinct biological function in the malignant transformation of gastric epithelial cells.

The 70-kDa S6 kinase (p70S6K) is a cytoplasmic Ser/Thr kinase that is mainly known to regulate protein translation through phosphorylation of the 40S ribosomal protein S6. Activation of p70S6K is achieved through phosphorylation on multiple Ser/Thr residues by stimulation with growth factors such as epidermal growth factor (EGF), thrombin, and lysophosphatidic acid (LPA)[23,24]. To the role of phospho-p0S6K protein in the progression of gastric carcinoma, its expression was compared with the aggressive behaviors of carcinoma and for the first time found that nuclear phosphor-P70S6K expression was inversely linked to tumor size, depth of invasion, lymph node metastasis and UICC staging. It was suggested that down-regulated expression of nuclear phospho-P70S6K was involved in the growth, invasion and metastasis of gastric carcinoma and might be employed to indicate the biological behaviors of gastric carcinoma in clinicopathological practice.

PR = positive rate; T1 = carcinoma in situ; T2 = lamina propria and submucosa; T3 = muscularis propria and subserosa; T4 = exposure to serosa; T4 = invasion into serosa; UICC = Union Internationale Contre le Cancer

Although gastric cancer is malignant tumor originating from the same gastric epithelium, its morphological features vary substantially with the individual patients [13].
According to Lauren’s classification, intestinal-type carcinomas are characterized by cohesive carcinoma cells forming gland-like tubular structures with expanding or infiltrative growth pattern. The cell cohesion is less apparent or absent in diffuse-type carcinoma and cancer cells diffusely spread in the gastric wall lesions. Tumors that contain approximately equal quantities of intestinal and diffuse components are called mixed carcinoma [13,14].

These three markers were preferably expressed in the older patients with gastric cancer and intestinal-type carcinoma. Here, it was noted that mTOR, cytoplasmic and nuclear P70S6K expression was higher in intestinal-than diffuse-type carcinomas, indicating that these three markers might play an important role in intestinal-type carcinogenesis, but less in de novo carcinogenic pathway and underlie the molecular basis for differentiation of both carcinomas.

To clarify the prognostic significance of mTOR, cytoplasmic or nuclear P70S6K expression, we here analyzed their relation with the survival of 412 patients with gastric carcinoma and found a close relationship link between the positivity of mTOR and nuclear phospho-P70S6K expression and favorable survival. Multivariate analysis demonstrated six independent prognostic factors such as age, depth of invasion, lymphatic invasion, lymph node metastasis, Lauren’s classification and mTOR expression were independent prognostic factors for overall gastric carcinomas. However, several evidences indicated that phosphor-mTOR expression was closely linked to the poor prognosis of the patients with cervical adenocarcinoma or hepatocellular carcinoma [18,25]. PS6K overexpression was reported to correlate with worse distant disease-free survival of early-stage breast cancer patients. The paradoxical phenomenon might be attributed to the different mTOR types or different subcellular distribution of p70S6K protein. Here, nuclear p70S6K was inversely related to the tumor size, depth of invasion, lymph node metastasis and UICC staging, which are aggressive appearances of gastric cancer. The finding indicated p70 S6 phos-

phorylation in the nucleus might play some inhibitory role in gastric cancer and subsequent progression distinct from that in the cytoplasm.

**Conclusion**

Aberrant expression of p-P70S6K might play an important role of malignant transformation of gastric epithelial cells and was closely related to growth, invasion, metastasis and prognosis of gastric carcinomas and was considered as a promising marker to indicate the pathobiological behaviors. The distinct expression of mTOR and p-P70S6K could be employed to differentiate the intestinal- and diffuse-type carcinomas and underlay the molecular mechanism about the differentiation of both carcinomas.

**Table 6: Relationship between nuclear P70S6K expression and clinicopathological features of gastric carcinomas**

| Clinicopathological features | N | Nuclear P70S6K expression | PR(%) | P value |
|-----------------------------|---|--------------------------|-------|---------|
| Age(years)                  |   | - | + | ++ | +++ | | | 0.042 |
| <65                         | 165 | 86 | 49 | 20 | 10 | 47.9 |
| ≥65                         | 39  | 102 | 74 | 53 | 10 | 57.3 |
| Sex                         |   |   |   |   |   | 0.172 |
| Male                        | 282 | 127 | 85 | 54 | 16 | 55.0 |
| Female                      | 122 | 61  | 38 | 19 | 4  | 50  |
| Tumor size(cm)              |   |   |   |   |   | 0.001 |
| <4                          | 210 | 86  | 59 | 52 | 13 | 59.0 |

**Table 7: Multivariate analysis of clinicopathological variables for survival with gastric carcinomas**

| Clinicopathological parameters | Relative risk (95%CI) | p value |
|--------------------------------|-----------------------|---------|
| Age(≥ 65 years)                | 1.857(1.206-2.859)    | 0.005   |
| Sex(male)                      | 1.587(0.977-2.577)    | 0.062   |
| Tumor size(≥ 4)                | 1.372(0.776-2.426)    | 0.277   |
| Depth of invasion (T<sub>2-4</sub>) | 2.793(1.323-5.898)    | 0.007   |
| Lymphatic invasion(+)          | 2.086(1.230-3.538)    | 0.006   |
| Venous invasion(+)             | 1.080(0.663-1.758)    | 0.758   |
| Lymph node metastasis(+)       | 2.842(1.463-5.523)    | 0.002   |
| Lauren’s classification (diffuse-tape) | 1.914(1.178-3.110)    | 0.009   |
| mTOR (+-+++                   | 0.737(0.547-0.992)    | 0.044   |
| Cytoplasmic P70S6K expression (+-+++ | 1.061(0.765-1.472)    | 0.724   |
| Nuclear P70S6K expression (+-+++ | 0.854(0.625-1.166)    | 0.320   |

CI = confidence interval.
Nuclear p-p70S6K was a good marker to indicate the favorable prognosis of gastric carcinoma patients, albeit dependent on other parameters, but mTOR expression was an independent factor for the prognosis.

**Competing interests**
The authors declare that they have no competing interests.

**Authors’ contributions**
LX designed the research and wrote the paper. WSL and YCW carried out the the immunoassays and collected the gastric cancer tissues. LX and WSL carried out the pathological diagnosis and data analysis. YD prepared the Tissue microarray. All authors have read and approved the manuscript.

**Figure 2**
Correlation between mTOR or p70S6K status and prognosis of the gastric carcinoma patients. Kaplan-Meier curves for cumulative survival rate of patients with gastric carcinomas according to the mTOR(A) and cytoplasmic(B) or nuclear (C) p70S6K expression in gastric carcinomas.
