SELF-DUAL MAPS I : ANTIPODALITY

LUI S MONTEJANO¹, JORGE L. RAMÍREZ ALFONSÍN², AND IVAN RASSKIN

ABSTRACT. A self-dual map $G$ is said to be antipodally self-dual if the dual map $G^*$ is antipodal embedded in $S^2$ with respect to $G$. In this paper, we investigate necessary and/or sufficient conditions for a map to be antipodally self-dual. In particular, we present a combinatorial characterization for map $G$ to be antipodally self-dual in terms of certain involutive labelings. The latter lead us to obtain necessary conditions for a map to be strongly involutive (a notion relevant for its connection with convex geometric problems). We also investigate the relation of antipodally self-dual maps and the notion of antipodally symmetric maps. It turns out that the latter is a very helpful tool to study questions concerning the symmetry as well as the amphicheirality of links.

1. Introduction

Let $G$ be a map, that is, a graph cellularly embedded in the sphere. Then $G = (V, E, F)$ has a natural geometric dual $G^* = (V^*, E^*, F^*)$ where each face in $F$ correspond to a vertex in $V^*$ and two vertices in $V^*$ are adjacent if the corresponding faces in $G$ share an edge. A map $G$ is called self-dual if there is a bijection from $V$ and $F$ to $V^*$ and $F^*$ which reverses inclusion.

Self-dual maps have been the subject of numerous investigations in different fronts: self-dual polyhedra and ranks [3], isometries in $S^2$ [8], eigenvalues of $h$-graphs [11], rigidity [7], tilings [9], etc.

A self-dual map $G$ is said to be antipodally self-dual if the dual map $G^*$ is antipodally embedded with respect to $G$. In other words, the map $G$ is antipodally self-dual if the following holds for any $x \in S^2$

1) if $x \in V(G)$ then $-x \in V(G^*)$ and

2) if $x \in e \in E(G)$ then $-x \in e^* \in E(G^*)$, that is, $e^*$ is antipodally embedded in $S^2$ with respect to the embedding of $e$.

Antipodally self-dual maps are closely related with the notion of strongly involutive maps (see beginning of Section 3.1) and thus relevant for their connection with convex geometric problems as the well-known Vázsonyi’s problem on ball polyhedra (as reported in [2], see also [10]), the chromatic number of distance graphs on the sphere [4] and Reuleaux polyhedra [5]. As we will see, antipodally self-dual maps are also closely related with the notion of antipodally symmetric maps. The latter turns out very useful to study questions concerning the symmetry as well as the amphicheirality of links, see [6].

The main goal of this paper is to investigate necessary and/or sufficient conditions for a map to be antipodally self-dual.

The paper is organized as follows. In the next section, we give a brief overview of some notions on self-dual maps needed for the rest of the paper. Given a map $G$, we recall three special close related maps (medial graph $\text{med}(G)$, square graph $G^\square$ and vertex-face incidence graph $I(G)$) that turn out to be very useful for our propose.

In Section 3, we first recall some classical results between isometries in $S^2$ and maps. We then present a result giving necessary conditions of an antipodally self-dual map $G$ in terms of symmetric cycles in $I(G)$ (Theorem 1). Afterwards, we discuss the connection between antipodally self-dual maps and strongly involutive maps and give a combinatorial characterization for a map $G$ to be antipodally self-dual in terms of certain involutive labelings of $I(G)^\square$ (Theorem 2). As a consequence, we obtain necessary conditions for a map $G$ to be strongly involutive in terms of $I(G)^\square$ (Corollary 2).

In Section 4, we characterize three different infinite families of antipodally self-dual maps (Propositions 1, 2 and 3). We also present a more general construction (Theorem 3).

In Section 5, we study antipodally symmetric maps. Besides many properties, we show that if $G$ is an antipodally self-dual map then both $\text{med}(G)$ and $I(G)$ are antipodally symmetric maps (Lemma 3).

2. Maps preliminaries

Let $G$ be a planar graph. A map of $G = (V, E, F)$ is the image of an embedding of $G$ into $S^2$ where the set of vertices are a collection of distinct points in $S^2$ and the set of edges are a collection of Jordan curves joining two points in $V$ satisfying that $\alpha \cap \alpha'$ is either empty or a point in the endpoints for any pair of Jordan curves $\alpha$ and $\alpha'$. Any embedding of the topological realization of $G$ into $S^2$ partitions the 2-sphere into simply connected regions of $S^2 \setminus G$ called the faces $F$ of the embedding.

Given a map $G$, we may construct the dual map $G^* = (V^*, E^*, F^*)$ by placing a vertex $f^*$ in the interior of each face $f$ of $G$, and for each edge $e$ of $M$ draw a dual edge $e^*$ connecting the vertices $f_1^*$ and $f_2^*$ (corresponding to the two faces $f_1$ and $f_2$ sharing edge $e$) by crossing $e$ transversely. We denote by $X(G, G^*)$ the set of intersection points of map $G$ and map $G^*$.

Two maps $G_1 = (V_1, E_1, F_1)$ and $G_2 = (V_2, E_2, F_2)$ of the same graph are isomorphic if there is an isomorphism $\phi : (V_1, E_1, F_1) \rightarrow (V_2, E_2, F_2)$ preserving incidences. We say that a map $G = (V, E, F)$ is a self-dual map if the maps $G = (V, E, F)$ and $G^* = (V^*, E^*, F^*)$ are isomorphic, that is, there is an isomorphism $\phi : (V, E, F) \rightarrow (F^*, E^*, V^*)$ preserving incidences.

Given maps $G = (V, E, F)$ and $G^* = (V^*, E^*, F^*)$ we define the following auxiliaries maps:

- The squares graph of $G$ is the map $G^\square$ obtained by the simultaneous drawing of $G \cup G^*$ with all the edges split at the intersection points of an edge $e$ with its dual edge $e^*$. We thus have that every face of $G^\square$ is a square formed by half-edges of $G$ and $G^*$.

For each square face in $G^\square$, we define two types of diagonals: the intersecting diagonal which is the edge joining the intersections points and the incidence diagonal which is the edge joining a vertex in $V(G)$ to a vertex in $V(G^*)$. 

- The *vertex-face incidence graph* is the map $I(G)$ having as vertices $V \cup V^*$ and as edges are all the incidence diagonals of $G^\square$.

- The *medial of $G$* is the map $med(G)$ having as vertices the set of intersections points of $E \cap E^*$ and as edges the set of all the intersecting diagonals of $G^\square$.

Figure 1. A map and its dual, the squares graph, the vertex-face incidence graph and the medial.

Throughout the paper, we will represent the vertices of $G$ with black circles, the vertices of $G^*$ with white circles and the intersection points with white squares and the vertices of the medial with transparent squares.

Notice that $I(G)$ and $med(G)$ are dual from each other for any map $G$. Hence, we can construct the squares graph of the vertex-face incidence graph which it turns out to be very useful for our propose.

Figure 2. (Right) $I(G)$ (straight edges and black and vertices in white circles) and $med(G)$ (dashed edges and vertices in transparent squares) (Left) Graph $I(G)^\square$. 
3. ANTIPODALLY SELF-DUAL MAPS

We recall that $\text{Aut}(G)$ is the group formed by the set of all automorphism of $G$ (i.e., the set of isomorphisms of $G$ into itself). We will denote by $\text{Iso}(G)$ the set of all duality isomorphisms of $G$ into $G^*$. We notice that $\text{Iso}(G)$ is not a group since the composition of any two of them is an automorphism.

Let us suppose that $G = (V,E,F)$ is a self-dual map so that there is a bijection $\phi : (V,E,F) \rightarrow (F^*,E^*,V^*)$. Following $\phi$ with the correspondence $\ast$ gives a permutation on $V \cup E \cup F$ which preserve incidences but reverses dimension of the elements. The collection of all such permutations or self-dualities generate a group $\text{Dual}(G) = \text{Aut}(G) \cup \text{Iso}(G)$ in which the automorphisms $\text{Aut}(G)$ are contained as a subgroup of index 2.

It is known [8, Lemma 1] that for a given map $G$ there is an homeomorphism $\rho$ of $S^2$ to itself such that for every $\sigma \in \text{Aut}(G)$ we have that $\rho \sigma \in \text{Isom}(S^2)$ where $\text{Isom}(S^2)$ is the group of isometries of the 2-sphere. In other words, any planar graph $G$ can be drawn on the 2-sphere such that any automorphism of $G$ act as an isometry of the sphere. This was extended in [8] by showing that given any self-dual graph $G$ there are maps $G$ and $G^*$ so that $\text{Dual}(G)$ is realized as a group of spherical isometries.

From now on, we will denote by $\widehat{G} = \rho(G)$ and $\widehat{\sigma} = \rho \sigma$ for a certain homeomorphism $\rho$ satisfying the above property.

A self-dual map $G$ is antipodally self-dual if $-\widehat{G} = \widehat{G}^*$ where $-G$ is the map consisting of the set of points $\{-x \in S^2 \mid x \in G\}$.

Let us present a result giving necessary combinatorial conditions for a map to be antipodally self-dual. By a symmetric cycle $C$ of a planar graph $G$ we mean there is an automorphism $\sigma(G)$ such that $\sigma(C) = C$ and $\sigma(\text{int}(C)) = \text{ext}(C)$, that is, the induced graph in the interior of $C$ is isomorphic to the induced graph in the exterior of $C$.

**Theorem 1.** Let $G$ be antipodally self-dual. Then, $I(G)$ always admit at least one symmetric cycle. Moreover, all symmetric cycles in $I(G)$ are of length $2n$ with $n \geq 1$ odd.

We will prove Theorem 1 at the end of Section 3 where the notion of antipodally symmetric is discussed (and needed for the proof).

**Remark 1.** An antipodally self-dual map $G$ induces an involutive self-dual isomorphism $\sigma : V(G) \rightarrow V^*(G)$. The converse is not necessarily true, there are self-dual graphs not admitting an antipodally self-dual map. For instance, the graph $G'$ illustrated in Figure 3 is self-dual but it is not antipodally self-dual. Indeed, it can be easily checked that $I(G')$ admits a symmetric cycle of length 8 (implying that $G'$ is not antipodally self-dual, by Theorem 7), see Figure 3.
3.1. **Strongly involutive maps and involutive labelings.** Let $G$ be a self-dual graph with duality isomorphism $\sigma : G \rightarrow G^*$. We say that $G$ is **strongly involutive** if the following conditions are satisfied:

a) for each pair of vertices $u, v \in V(G)$, $u \in \sigma(v)$ if and only if $v \in \sigma(u)$ and

b) for every vertex $v \in V(G)$, we have that $v \notin \sigma(v)$.

We notice that a) is equivalent to say that $\sigma^2 = id$.

The above conditions are the combinatorial counterpart (in the 3-dimensional case) of a more general geometric object called strong self-dual polytopes, first introduced by Lovász in [4]. Antipodally self-dual maps are closely related with strongly involutive isomorphism. Indeed, in [1, Theorem 9], it was proved that if $G$ is strongly involutive then $G$ is antipodally self-dual. As we will see below, the latter is a straightforward consequence of Theorem 2 (see Corollary 2).

Let $G = (V, E, F)$ be a map and let $X^+ = \{x_1, \ldots, x_m\}$ and $X^- = \{\overline{x}_1, \ldots, \overline{x}_m\}$ be two sets with $1 \leq m \leq |V|$ and the property $\overline{x}_i = x_i$. Let $\mathcal{P}(X^+ \cup X^-)$ be the set of subsets of $X^+ \cup X^-$. An **involutive labeling** of $G$ is a function $\Lambda : V \rightarrow \mathcal{P}(X^+ \cup X^-)$ satisfying the following properties:

(i) $|\Lambda(v)| = 1, 2$ for every $v \in V$.

(ii) If $|\Lambda(v)| = 2$ then $\Lambda(v) = \{x_i, \overline{x}_i\}$ for some $1 \leq i \leq m$. In this case, we say that $v$ is a **fixed vertex** of $\Lambda$ and we write $x_i = \overline{x}_i$ (instead of $\{x_i, \overline{x}_i\}$).

(iii) $\Lambda(u) \cap \Lambda(v) \neq \emptyset$ if and only if $u = v$.

(iv) $\{\Lambda^{-1}(x_i), \Lambda^{-1}(\overline{x}_j)\} \in E$ if and only if $\{\Lambda^{-1}(x_i), \Lambda^{-1}(\overline{x}_j)\} \in E$ where $\Lambda^{-1}(x_i) := \{v \in V : x_i \in \Lambda(v)\}$.

Let $G^\square = (V^\square, E^\square, F^\square)$ be the square graph associated to a map $G = (V, E, F)$. Recall that $V^\square = V_V \cup V_E \cup V_F$ where $V_V$ are the vertices of $G$, $V_E$ are the vertices on the edges of $G$ and $V_F$ are the vertices of $G^*$ (one for each face of $G$).
Remark 2. An involutive labeling of $I(G)^\square$ naturally induces an automorphism of $I(G)$

$$\sigma_\Lambda : V \cup V^* \to V \cup V^*$$
$$v \mapsto \Lambda(v)$$

where $\Lambda(u) = \overline{\Lambda(v)}$ (the adjacency preserving property of $\sigma_\Lambda$ is obtained from (ii)).

a) If vertex $v$ was assigned labels $k$ and $\bar{k}$ (and thus $k = \bar{k}$) then it will be a fixed vertex under $\sigma_\Lambda$.

b) $\sigma_\Lambda^2 = \text{Id}$.

c) $\sigma_\Lambda$ corresponds to an involutive duality isomorphism $\sigma : G \to G^*$ if and only if the labels of the black vertices are the opposite to those of the white vertices in $I(G)^\square$.

Remark 3. Let $G$ be a self-dual map. We have that $G$ is strongly involutive if and only if $I(G)$ admits an involutive labeling without edges which extremes are labeled by $k$ and $\bar{k}$.

3.2. Characterizing antipodally self-dual maps. We are interested in giving necessary and sufficient combinatorial conditions for a map to be antipodally self-dual.

Remark 4. We have that any $\sigma \in \text{Aut}(G)$ naturally induces $\sigma^\square \in \text{Aut}(G^\square)$ with $\sigma^\square$ preserving incidences, that is, if $v_V \in V_V$ is adjacent to $v_E \in V_E$ (resp. $v_E \in V_E$ is adjacent to $v_F \in V_F$) then $\sigma^\square(v_V)$ is adjacent to $\sigma^\square(v_E)$ (resp. $\sigma^\square(v_E)$ is adjacent to $\sigma^\square(v_F)$) and where $V_V, V_E$ and $V_F$ are mapped to $V_V, V_E$ and $V_F$ respectively. We finally notice that there might exist $\gamma \in \text{Aut}(G^\square)$ not necessarily arising from an automorphism of $G$.

Lemma 1. Let $H$ be a map and let $\sigma \in \text{Aut}(H)$. Then, $\hat{\sigma}$ has a fixed point in $S^2$ if and only if $\sigma^\square$ has a fixed vertex in $H^\square$.

Proof. Let $x \in S^2$. A point $x$ corresponds to a vertex on $H^\square$, say $x^\square$, which lies properly on either $V, E$ or $F$. If $\hat{\sigma}(x) = x$ then $\sigma^\square(x^\square) = x^\square$.

Conversely, let $v \in V^\square = \{V_V \cup V_E \cup V_F\}$ such that $\sigma^\square(v) = v$. We have three cases.

Case 1) $v \in V_V$. Then, the point $v \in S^2$ is such that $\hat{\sigma}(v) = v$.

Case 2) $v \in V_E$. Suppose $v$ lies properly on an edge $e$. We know that the isometry $\hat{\sigma}$ maps $e$ into itself. Since $e$ is topologically equivalent to $\mathbb{B}^1$ then $\hat{\sigma}$ is a continuous function sending $\mathbb{B}^1$ to itself. Therefore, by the Brouwer fixed-point theorem there is $x \in e$ such that $\hat{\sigma}(x) = x$.

Case 3) $v \in V_F$. Suppose $v$ lies properly on a face $f$. We proceed as in the Case 2. The isometry $\hat{\sigma}$ maps $f$ into itself. Since $f$ is topologically equivalent to $\mathbb{B}^2$ then $\hat{\sigma}$ is a continuous function sending $\mathbb{B}^2$ to itself. Therefore, by the Brouwer fixed-point theorem there is $x \in f$ such that $\hat{\sigma}(x) = x$. \qed

Theorem 2. Let $G = (V, E, F)$ be a self-dual map. Then, $G$ is antipodally self-dual if and only if $I(G)^\square$ admits an involutive labeling without fixed vertices.

Proof. Suppose that $G$ is antipodally self-dual. Therefore, there is $\hat{G}$ isomorphic to $G$ such that $-\hat{G} = \hat{G}^*$. Let $a : x \mapsto -x$ be the antipodal mapping of $S^2$. We have that $a$ naturally induces the automorphisms $a_I \in \text{Aut}(I(\hat{G}))$ and $a^\square \in \text{Aut}(I(\hat{G})^\square)$ . Furthermore, since $a$ is the antipodal mapping then

- $a_I^2 = \text{Id}$ (implying that $I(G)^\square$ admits an involutive labeling on its vertices) and
• $a_I$ has no fixed points of $S^2$. Therefore, by Lemma 1, $a^\square$ has no fixed vertices and thus the above involutive labeling of $I(G)^\square$ has no fixed vertices.

We finally notice that an involutive labeling of $I(\hat{G})^\square$ is also an involutive labeling of $I(G)^\square$.

Conversely, suppose that $I(G)^\square$ admits an involutive labeling without fixed vertices. By Lemma 1, $\hat{\sigma}(I(G))$ has not a fixed point in $S^2$. Now, there are three sphere isometries such that $\sigma^2 = Id$: rotation of $\pi$ degree, reflexion on a hyperplane and the antipodal function. Among them, it is the antipodal function the only without fixed points. Moreover, since $\sigma: G \to G^*$ then $\sigma$ sends vertices of $G$ to vertices of $G^*$. Therefore, $G$ is antipodally self-dual.

For the involutive labelings of squares graphs, we shall use integers (and their opposites) for vertices of type $V_V$, letters (and their opposites) for vertices of type $V_E$ and greek letters (and their opposites) for vertices of type $V_E$. On one hand Figure 4 illustrates a self-dual map $G$ and $I(G)^\square$ together with an involutive labeling without fixed vertices. Therefore, as a consequence of Theorem 2, $G$ is antipodally self-dual. On the other hand, Figure 5 illustrates an involutive labeling of the 4-wheel $W_4$ with $I(W_4)^\square$ admitting two fixed vertices. In fact, it can be checked that any involutive labeling of $I(W_4)^\square$ admits at least one fixed vertex since $W_4$ is not antipodally self-dual (see Proposition 1).

![Figure 4](image-url)

**Figure 4.** (Left) A self-dual map $G$ (straight edges and black vertices) and $G^*$ (dashed edges and white vertices). It can easily be checked that $G$ do not admit a strongly involutive isomorphism. (Right) An involutive labeling of $I(G)^\square$ without fixed vertices.
Corollary 1. Let $G$ be a self-dual map. If there is a black vertex of $I(G)$ connected to each white vertex of $I(G)$ by an odd number of edges then $G$ is not antipodally self-dual.

Proof. Let $v$ be such a black vertex. Since $v$ is connected to all the white vertices then for any involutive labeling $\Lambda$ of $I(G)$ there is an edge in $I(G)$ with ends labeled with $k$ and $\overline{k}$. By Remark 2, the automorphism $\sigma_{\Lambda}(G)$ maps an edge with ends labeled $\{k, \overline{k}\}$ to an edge with ends labeled $\{k, \overline{k}\}$. Since, by hypothesis, there is an odd number of edges then there must be an edge mapped to itself which correspond to a fixed vertex in $V(I(G))$. Therefore, by Theorem 2, $G$ is not antipodally self-dual. \qed

Figure 6 illustrates a graph in which $I(G)$ has a vertex in $V(G)$ adjacent to each vertex of $G^*$ by an odd number of edges (and thus, by Corollary 1, $G$ is not antipodally self-dual).
**Corollary 2.** Let $G$ be a self-dual map. If $G$ is strongly involutive then $G$ is antipodally self-dual.

Proof. We shall show that $I(G)^\sqsubset$ admits an involutive labeling without fixed vertices. The result then follows by Theorem 2.

Let $\sigma : G \rightarrow G^*$ be a duality isomorphism. We thus have that $\sigma$ does not fix vertices. Recall that if $G$ is strongly involutive then $\sigma$ verifies

a) for each pair of vertices $u, v \in V(G), u \in \sigma(v)$ if and only if $v \in \sigma(u)$ and

b) for every vertex $v \in V(G)$, we have that $v \notin \sigma(v)$.

As remarked above, a) is equivalent to say that $\sigma^2 = id$. We clearly have that $\sigma$ does not fix vertices since it maps vertices of $G$ to vertices of $G^*$. The latter implies that $\sigma_I$ does not fix vertices in $I(G)$ and thus neither $\sigma^\sqsubset$ in $I(G)^\sqsubset$.

Now, by combining conditions (a) and (b) we obtain that $u \notin \sigma(u)$ for every vertex $u$ in $G^*$. The latter implies that $I(G)$ does not admit an edge with extremes labeled with $k$ and $\bar{k}$ and so $\sigma^\sqsubset$ does not fix vertices of type $V_E$ (i.e., arising from edges of $I(G)$) in $I(G)^\sqsubset$.

We finally claim that $\sigma^\sqsubset$ does not fix vertices of type $V_F$ (i.e., arising from faces of $I(G)$) in $I(G)^\sqsubset$. We proceed by contradiction, suppose that $\sigma^\sqsubset$ fixes a vertex $u_f$ arising from a face $f$ of $I(G)$. Let $f$ be the face in $I(G)$ corresponding to $\sigma(u_f)$. Recall that all the faces in $I(G)$ are squares, suppose that $f = \{w, x, y, z\}$ with $w, y \in V(G)$ and $x, z \in V(G^*)$ and $f' = \{w', x', y', z'\}$ with $w', y' \in V(G)$ and $x', z' \in V(G^*)$.

Since $\sigma^\sqsubset$ fixes $u_f$ then $\sigma(u_f) = u_f$ but this happen only if $\{\sigma(w), \sigma(y)\} = \{w', y'\}$ and $\{\sigma(x), \sigma(z)\} = \{x', z'\}$. The latter implies the existence of an edge with extremes labeled $k$ and $\bar{k}$, which is not possible. \hfill \Box

We notice that the converse of Corollary 2 is not necessarily true. Indeed, there might be a non strongly involutive map $G$ with $I(G)^\sqsubset$ admitting an involutive labeling without fixed vertices (and thus $G$ antipodally self-dual, by Theorem 2), see Figure 4.

4. Infinite families

We give below some infinite families having antipodally self-dual maps. For, it is given an appropriate strongly involutive duality-isomorphism. We will present a result giving sufficient and necessary conditions for a map to be antipodally self-dual in Section 3.2 (Theorem 2) which can also be used to verify that the below families are antipodally self-dual. The latter is based on involutive isometries in $S^2$ without fixed points.

4.1. The wheel. Let $n \geq 3$ be an integer. The $n$-wheel, denoted by $W_n$, is the graph consisting of an $n$-cycle with a center joined to each vertex of the cycle.

**Proposition 1.** The $n$-wheel is antipodally self-dual if and only if $n \geq 3$ is odd.

Proof. It can be easily checked that $W_n$ admits a strongly involutive duality-isomorphism for any odd integer $n \geq 3$, see Figure 7. Moreover, if $n$ is even then $I(W_n)$ admits a symmetric cycle of length $2k$ with $k$ even, see Figure 8. Thus, by Theorem 1, $W_n$ is not antipodally self-dual. \hfill \Box
Figure 7. 3-wheel and 5-wheel together with a strongly involutive duality-isomorphism given by $\sigma(k) = \bar{k}$.

Figure 8. $I(W_4)$ admitting a symmetric cycle (bold edges) of length 8.

Figure 9 (a) shows that $W_3$ admits an antipodally self-dual map. One can easily mimic this embedding for any odd integer $n \geq 3$. Figure 9 illustrates the case $n = 5$.

Figure 9. A antipodally self-dual map of $W_5$ (straight edges and black vertices) and its dual (dashed edges and white vertices). Antipodal vertices are given by $k$ and $\bar{k}$.
4.2. The \( n \)-ear. Let \( n \geq 3 \) be an integer. The \( n \)-ear, denoted by \( E_n \) is the graph consisting of a \( n \)-cycle with an ear added on each edge and a center is joined to each ear, see Figure 10.

**Proposition 2.** The \( n \)-ear is antipodally self-dual if and only if \( n \geq 4 \) is even.

**Proof.** It can be easily checked that \( E_n \) admits a strongly involutive duality-isomorphism for any even integer \( n \geq 4 \), see Figure 10. Moreover, if \( n \) is odd then \( I(E_n) \) admits a symmetric cycle of length \( 2k \) with \( k \) even, see Figure 11. Thus, by Theorem 1, \( W_n \) is not antipodally self-dual. □

![Figure 10](image1.png)

**Figure 10.** The 4-ear and 6-ear graphs together with strongly involutive duality-isomorphisms given by \( \sigma(k) = \bar{k} \).

![Figure 11](image2.png)

**Figure 11.** \( I(3\text{-ear}) \) admitting a symmetric cycle (bold edges) of length 12.

The map \( E_4 \) given in Figure 12 shows that 4-ear graph is antipodally self-dual. One can easily mimic this embedding for any even integer \( n \geq 4 \).
4.3. The \((n, \ell)\)-pancake. Let \(n \geq 3\) and \(\ell \geq 1\) be integers. The \((n, \ell)\)-pancake, denoted by \(P_{n}^{\ell}\), is the graph consisting of \(\ell\) cycles \(\{v_1^1, \ldots, v_n^1\}, \ldots, \{v_1^\ell, \ldots, v_n^\ell\}\), a vertex \(v_0^\ell\) and edges \(\{v_{i}^{j-1}, v_i^j\}\) for each \(j = 1, \ldots, n\) and all \(i\), see Figure 13.

**Proposition 3.** The \((n, \ell)\)-pancake is antipodally self-dual if and only if \(n \geq 3\) is odd for all \(\ell \geq 1\).

**Proof.** It can be easily checked that \((n, \ell)\)-pancake admits a strongly involutive duality-isomorphism for all integers \(n \geq 3, \ell \geq 1\) with \(n\) odd, see Figure 13. Moreover, if \(n\) is even then \(I((n, \ell)\text{pancake})\) admits a symmetric cycle of length \(2k\) with \(k\) even, see Figure 14. Thus, by Theorem 1, \((n, \ell)\)-pancake is not antipodally self-dual. \(\square\)
Figure 13. $P_2^2$ and $P_5^3$ together with a strongly involutive duality-isomorphism given by $\sigma(k) = \overline{k}$.

Figure 14. $I(P_4^2)$ admitting a symmetric cycle (bold edges) of length 8.

The map of $P_5^2$ given in Figure 15 shows that $(3, 2)$-pancake is self-dual antipodal. One can easily mimic this embedding for any odd integer $n \geq 3$ and any $\ell \geq 1$. 
4.4. Adhesion construction. Let us give a way to construct infinite families of antipodally self-dual graphs. The latter is based on a procedure to construct self-dual graphs called the adhesion, given in [7]. Let $G$ be a planar connected graph and let $G^*$ be its geometric dual. Let $x$ (resp. $x^*$) be the vertex corresponding to the exterior face of $G^*$ (resp. exterior face of $G^{**} = G$). We define the graph $G \diamond G^*$ obtained by identifying $x$ and $x^*$, see Figure 16.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure16.png}
\caption{(Left) Draw of $G$ and its dual. (Right) The adhesion of $G$.}
\end{figure}

Lemma 2. [7] Let $G$ be a planar connected graph. Then, the graph $G \diamond G^*$ is self-dual.

Proof. $H = G \diamond G^*$ is clearly self-dual since $H^* = (G \diamond G^*)^* = G^* \diamond G = G \diamond G^*$. \hfill \Box

Notice that in the construction of $G \diamond G^*$ the couple $x$ and $x^*$ cannot be replaced by any pair of vertices since we may end up with a not self-dual graph, see Figure 17.

\end{figure}
Theorem 3. Let $G$ be a planar connected graph. Then, $G \diamond G^*$ is antipodally self-dual.

Proof. By Lemma 2 $H = G \diamond G^*$ is self-dual. Let us show that $H$ admits an antipodal map. Let $x$ (resp. $x^*$) be the vertex corresponding to the exterior face of $G^*$ (resp. exterior face of $G = G^{**}$). We first draw $G$ and its dual within a circle $C$ such that $x$ and $x^*$ are antipodal points on $C$ and no other edge or vertex (of $G$ or $G^*$) lie on $C$, see Figure 18.

We shall construct two embeddings (one in the Northern hemisphere and the other in the Southern one) that will be glued together giving the desired antipodally self-dual embedding of $H$. For, we consider $C$ as the equator of $S^2$ and project our drawing perpendicularly to the Northern hemisphere of $S^2$. We then take the antipodal of the latter embedding, obtaining and embedding in the Southern hemisphere.

We finally glue together both embeddings along the equator ($x$ and $x^*$ are the only vertices that are identified twice on the equator). By construction, this is an antipodal map of $H$, see Figure 19.
Figure 19. (a) Embedding of the draws of $G$ and $G^*$ in the Northern hemisphere (b) Antipodal embedding of the draw of the Northern hemisphere (c) Antipodal embedding of $H = G \odot G^*$ (bold edges) and $H^*$ (dashed edges).

Question 1. Let $H$ be a antipodally self-dual graph with a cut-vertex. Is it true that $H = G \odot G^*$ where $G$ is a planar connected graph and $G^*$ its geometric dual?

5. ANTIPODALLY SYMMETRIC MAPS

A map $G$ is said to be antipodally symmetric if $-\hat{G} = \hat{G}$ where $-G$ is the map consisting of points $\{ -x \in S^2 \mid x \in G \}$.

Remark 5. (a) $med(G) = med(G^*)$.

(b) If $G$ is self-dual then $|V(med(G))|$ is even. Indeed, by Euler’s formula we have $|V(G)| + |F(G)| = 2 + |E(G)|$ where $F(G)$ denote the set of faces of $G$. Since $G$ is self-dual then $|V(G)| = |V(G^*)| = |F(G)|$ and thus $2|V(G)| = 2 + |E(G)|$ implying that $|E(G)| = |V(med(G))|$ is even.
Lemma 3. Let $G$ be an antipodally self-dual map. Then, $\text{med}(G)$ and $I(G)$ are antipodally symmetric.

Proof. We first show that $\text{med}(G)$ is self-dual. For, let us consider a antipodally self-dual map $G$, that is, the dual map $G^*$ is antipodally embedded with respect to the map $G$. The latter induces a map $G^\square$ in which square faces of $G^\square$ are partitioned into pairs that are antipodally embedded in $S^2$. Indeed, let $F = \{e_1, e_2, e_1^*, e_2^*\}$ be a face of $G^\square$ where $e_1, e_2$ (resp. $e_1^*, e_2^*$) are the two half-edge induced by $e \in E(G)$ (resp. induced by $e^* \in E(G^*)$). Since $G$ is antipodally self-dual then there is an edge $f^* \in G^*$ (resp. an edge $f \in G$) which is antipodally embedded to $e \in G$ (resp. to $e^* \in G^*$). We thus have that the corresponding half-edges $f_1^*, f_2^*$ (resp. $f_1, f_2$) are also antipodally embedded with respect to $e_1, e_2$ (resp. to $e_1^*, e_2^*$). Obtaining an other face $F^* = \{f_1, f_2, f_1^*, f_2^*\}$ which is antipodally embedded with respect to $F$.

We thus have that the intersecting diagonals corresponding to faces $F$ and $F^*$ can also be antipodally embedded. The results follows by recalling that $\text{med}(G)$ is given by all the intersecting diagonals of $G^\square$, see Figure 20.

![Figure 20](image)

**Figure 20.** (a) Embedding of $K_4$ (black vertices and straight edges), its dual (white vertices and dashed edges) and the vertices of the medial graph (little squares vertices) (b) $K_4$ (dashed edges) and its medial graph (in bold dashed edges) with two antipodal faces (in bold).

For $I(G)$, the proof goes in the same way as above but, this time, by considering the incidence diagonals instead of the intersecting diagonals. □

We end this section by proving Theorem 1.

**Proof of Theorem 1.** Let $G$ be a antipodally self-dual map. Let $\widehat{\text{med}}(G)$ be the drawing of $\text{med}(G)$ where all the automorphisms are isometries and let $E$ be the equator of $S^2$.

Suppose that $E$ does not contain any vertex of $\widehat{\text{med}}(G)$; Then, $E$ passes from a face $f$ of $\widehat{\text{med}}(G)$ to another face $f'$ that shares and edge with $f$. Since $\text{med}(G)^* = I(G)$ the pair faces $\{f, f'\}$ corresponds to a pair of adjacent vertices $\{v, v'\}$ in $V(I(G))$. Thus, the sequence
of faces \((f_1, \ldots, f_n = f_1)\) intersected by \(E\) (with the order induced by \(E\)) corresponds to a cycle \(C\) in \(I(G)\). Let \(\text{int}(C)\) (resp. \(\text{ext}(G)\)) be the subgraph of \(I(G)\) corresponding to the faces of \(\text{med}(G)\) lying on the northern (resp. southern) hemisphere. By Lemma 3, \(\text{med}(G)\) is antipodally symmetric so the northern faces and the southern faces of \(\text{med}(G)\) are antipodally drawn. Thus, \(\text{int}(C)\) is map isomorphic to \(\text{ext}(C)\) and thus \(C\) is a symmetric cycle of \(I(G)\).

Now, let us suppose that \(E\) passes through a vertex of \(\text{med}(G)\). Since the set of vertices of \(\text{med}(G)\) is finite there exists a point \(x \in \text{med}(G)\) such that \(x\) and \(-x\) are not vertices of \(\text{med}(G)\). Let \(E_\alpha\) be the the rotation of \(E\) of angle \(\alpha\) on the line passing through \(x\) and \(-x\). Let
\[
\beta = \min_{\alpha > 0} \{E_\alpha\text{ contains a vertex of }\hat{\text{med}}(G)\}.
\]
Then, \(E_{\beta/2}\) is a great circle of \(S^2\) which does not contain any vertex of \(\text{med}(G)\). By taking \(E_{\beta/2}\) as equator we can apply the above arguments to show that there exists a symmetric cycle of \(I(G)\).

Finally, if \(C\) is a symmetric cycle of \(I(G)\) then we can draw \(\hat{I}(G)\) with \(C\) being the equator of \(S^2\). Since \(G\) is antipodally self-dual, a black vertex \(v\) of \(\hat{I}(G)\) is antipodal to a white vertex \(-v\). Thus, the length of \(C\) must be \(2n\) with \(n \geq 1\) odd. \(\square\)
