(Received xx; revised xx; accepted xx)

The effect on dynamo action of an anisotropic electrical conductivity conjugated to an anisotropic magnetic permeability is considered. Not only is the dynamo fully axisymmetric, but it requires only a simple differential rotation, which twice challenges the well-established dynamo theory. Stability analysis is conducted entirely analytically, leading to an explicit expression of the dynamo threshold. The results show a competition between the anisotropy of electrical conductivity and that of magnetic permeability, the dynamo effect becoming impossible if the two anisotropies are identical. For isotropic electrical conductivity, Cowling’s neutral point argument does imply the absence of an azimuthal component of current density, but does not prevent the dynamo effect as long as the magnetic permeability is anisotropic.

Key words: Magnetohydrodynamics, Dynamo effect, Anisotropy

1. Introduction

The dynamo effect is a magnetic instability produced by the displacement of an electrically conducting medium, without the aid of a magnet or a remanent magnetic field. A part of the kinetic energy of the moving medium is thus transferred into magnetic energy. This process is the most likely candidate to explain the ubiquity of magnetic fields observed in astrophysical objects (Rincon 2019). The increasing resolution of numerical simulations of dynamo equations makes it possible to reproduce, ever better, the magnetic features measured in natural objects (Schaeffer et al. 2017). Experiments have also successfully demonstrated the possibility of dynamo action (Gailitis et al. 2001; Stieglitz & Müller 2001; Monchaux et al. 2007), although it remains difficult to replicate in the laboratory processes occurring on a geophysical or astrophysical scale (Alboussière et al. 2011; Tigrine et al. 2019). This is why, since the very first dynamo experiments (Lowes & Wilkinson 1963; 1968), the use of materials with the highest product of electrical conductivity and magnetic permeability, has been favoured. In most cases it led to the choice of solid iron alloys (high permeability) or liquid sodium (high conductivity) for the moving parts. In the VKS experiment, in which liquid sodium was driven by impellers, the high magnetic permeability of the impellers was revealed to be crucial to achieve a

F. Plunian, T. Alboussi`ere

dynamo effect (Miralles et al. 2013; Kreuzhler et al. 2017; Nore et al. 2018). The choice
of materials for the static parts, like the walls of the container, has also been proved to
be crucial in relation to the electromagnetic boundary conditions (Avalos-Zuñiga et al.
2003; Avalos-Zuñiga & Plunian 2005), leading for example to the use of copper walls
(Monchaux et al. 2007).

The role in the dynamo effect of an anisotropic electrical conductivity has been studied
for different geometries: Cartesian (Ruderman & Ruzmaikin 1984; Alboussi`ere et al.
2020), cylindrical (Plunian & Alboussi`ere 2020) and toroidal (Lortz 1989). Although at
first glance it is difficult to imagine such an anisotropic electrical conductivity in natural
objects, it is far from impossible. For example, in a plasma subjected to a magnetic field,
it is known that the electrical conductivity in the direction parallel to the magnetic field
is twice that in the direction perpendicular to the magnetic field (Braginskii 1965). In the
case of the Earth, seismic observations provide strong evidence that the elastic response of
the solid inner core is anisotropic. This is most likely due to the alignment of hexagonal
close-packed iron crystals, occurring during the solidification of the inner core (Deuss
2014). Incidentally it has been shown that, in hexagonal close-packed iron, the thermal
conductivity and the electrical conductivity, which are directly related, are anisotropic
(Ohta et al. 2018). Eventually, this suggests that the electrical conductivity of the inner
core is anisotropic. Finally, in a turbulent electrically conducting fluid, the interaction
between the small scales of the velocity field and those of the magnetic field can generate
a large-scale magnetic field by dynamo action. Such a process can be modeled using the
so-called mean-field approach (Krause & R¨ Adler 1980), possibly leading to a large-scale
anisotropic electrical conductivity (Brandenburg 2018).

From a theoretical point of view, an interesting consequence of considering an
anisotropic conductivity is the possibility of obtaining an axisymmetric dynamo effect
(Plunian & Alboussi`ere 2020), allowing one to bypass the well-known Cowling’s
antidynamo theorem (Cowling 1934; Kaiser & Tilgner 2014). Indeed, if it is anisotropic,
then the electrical conductivity becomes a tensor, instead of being a scalar, which defeats
Cowling’s neutral point argument. In addition, the use of an anisotropic conductivity
leads to dynamo action for a motion as simple as shear (Ruderman & Ruzmaikin 1984;
Alboussi`ere et al. 2020; Plunian & Alboussi`ere 2020), which is otherwise impossible to
achieve.

Here we investigate the role of an anisotropic electrical conductivity conjugated to an
anisotropic magnetic permeability. An anisotropic magnetic permeability is not expected
in natural objects. However, as explained above, this may be of interest for dynamo
experiments, in order to reduce the dynamo threshold. In contrast to previous dynamo
studies (Busse & Wicht 1992; Kaiser & Tilgner 1999), here the electrical conductivity
and magnetic permeability do not depend on time or space coordinates. In addition, they
are stationary and axisymmetric.

2. Conductivity and permeability anisotropy

We consider a material such that the electrical conductivity and magnetic perme-
ability are denoted $\sigma^\parallel$ and $\mu^\parallel$ in a given direction $\mathbf{q}$, and $\sigma^\perp$ and $\mu^\perp$ in the directions
perpendicular to $\mathbf{q}$.

Writing Ohm’s law, $\mathbf{J} = \sigma^\parallel \mathbf{E}$ in the direction of $\mathbf{q}$ and $\mathbf{J} = \sigma^\perp \mathbf{E}$ in the directions
perpendicular to $\mathbf{q}$, leads to the following conductivity tensor:

$$[\sigma_{ij}] = \sigma^\perp \delta_{ij} + (\sigma^\parallel - \sigma^\perp)q_i q_j.$$ (2.1)
Dynamo action with anisotropic conductivity and permeability

Figure 1. Left: The inner-cylinder of radius $R$ rotates as a solid-body within an outer cylinder at rest. The radius $R'$ of the outer cylinder is taken as infinite. Right: The curved lines are perpendicular to $q$ and describe logarithmic spirals. They correspond to the directions along which $\sigma = \sigma^\perp$ and $\mu = \mu^\perp$.

Inverting (2.1) leads to the resistivity tensor: [Ruderman & Ruzmaikin 1984]

$$[\sigma_{ij}]^{-1} = \frac{1}{\sigma^\perp} \delta_{ij} + \left( \frac{1}{\sigma^\parallel} - \frac{1}{\sigma^\perp} \right) q_i q_j.$$ (2.2)

Similarly, a magnetic permeability tensor can be defined as

$$[\mu_{ij}] = \mu^\perp \delta_{ij} + (\mu^\parallel - \mu^\perp) q_i q_j,$$ (2.3)

with the inverse tensor

$$[\mu_{ij}]^{-1} = \frac{1}{\mu^\perp} \delta_{ij} + \left( \frac{1}{\mu^\parallel} - \frac{1}{\mu^\perp} \right) q_i q_j.$$ (2.4)

We choose $q$ as a unit vector in the horizontal plane:

$$q = c \, e_r + s \, e_\theta,$$ (2.5)

where $(e_r, e_\theta, e_z)$ is a cylindrical coordinate system, with $c = \cos \alpha$ and $s = \sin \alpha$, $\alpha$ being a prescribed angle.

In figure 1 the curved lines are perpendicular to $q$ and describe logarithmic spirals. They correspond to the directions along which $\sigma = \sigma^\perp$ and $\mu = \mu^\perp$. We consider the solid-body rotation $U$ of a cylinder of radius $R$ embedded in an infinite medium at rest. Both regions are made of the same material, with therefore identical conductivity tensors and identical permeability tensors.
3. Induction equation

In the magnetohydrodynamic approximation, the Maxwell equations and Ohm’s law take the form

\[ H = [\mu_{ij}]^{-1} B, \]  
\[ J = \nabla \times H, \]  
\[ \partial_t B = -\nabla \times E, \]  
\[ \nabla \cdot B = 0, \]  
\[ J = [\sigma_{ij}] (E + U \times B), \]

where \( H, B, J, E \) and \( U \) are the magnetic field, the induction field, the current density, the electric field and the velocity field. The induction equation then takes the form

\[ \partial_t B = \nabla \times (U \times B) - \nabla \times ([\sigma_{ij}]^{-1} \nabla \times ([\mu_{ij}]^{-1} B)). \]  

Renormalizing the distance, electrical conductivity, magnetic permeability and time by respectively \( R, \mu^\perp, \sigma^\perp \) and \( \mu^\perp \sigma^\perp R^2 \), the dimensionless form of the induction equation is identical to (3.6), but with

\[ [\sigma_{ij}]^{-1} = \delta_{ij} + \sigma q_i q_j, \quad \sigma = \frac{\sigma^\perp}{\sigma^\parallel} - 1, \]  
\[ [\mu_{ij}]^{-1} = \delta_{ij} + \mu q_i q_j, \quad \mu = \frac{\mu^\perp}{\mu^\parallel} - 1, \]

and

\[ U = \begin{cases} r \Omega \Theta, & r < 1 \\ 0, & r > 1 \end{cases}, \]

where \( \Theta \) is the dimensionless angular velocity of the inner cylinder. We note that \((\sigma, \mu) \in [-1, +\infty]^2\), with \( \sigma = 0 \) and \( \mu = 0 \) corresponding to respectively isotropic conductivity and isotropic permeability.

Provided the velocity is stationary and \( z \)-independent, an axisymmetric magnetic induction can be searched in the form

\[ B(r, z, t) = \tilde{B}e_\theta + \nabla \times \left( \tilde{A} e_\theta \right), \]

with \((\tilde{A}, \tilde{B}) = (A(r), B(r)) \exp(\gamma t + i k z)\), where \( \gamma \) is the instability growth rate and \( k \) the vertical wavenumber of the corresponding eigenmode, and where \( A \) and \( B \) depend only on the radial coordinate \( r \). Thus the magnetic induction takes the form

\[ B = \left( -i k A, B, \frac{1}{r} \partial_r (r A) \right) \exp(\gamma t + i k z), \]

with dynamo action corresponding to \( \Re\{\gamma\} > 0 \).

From (3.9) and (3.11), it can be shown that \( \nabla \times (U \times B) = 0 \) in each region \( r < 1 \) and \( r > 1 \) (see appendix A). Replacing (3.7), (3.8) and (3.11) into the induction equation (3.6) leads to

\[ \gamma A + (1 + \sigma s^2) D_k(A) + \mu c^2 k^2 A = i csk(\sigma - \mu) B, \]  
\[ \gamma B + (1 + \mu s^2) D_k(B) + \sigma c^2 k^2 B = -icsk(\sigma - \mu) D_k(A), \]

where \( D_k(X) = \nu^2 X - \partial_r (\frac{1}{r} \partial_r (r X)) \). The derivation of (3.12) and (3.13) is given in appendix B. For \( \sigma = \mu = 0 \), corresponding to isotropy of both conductivity and permeability, (3.12) and (3.13) are diffusion equations, leading to a free decaying solution.
Thus, taking $\gamma(\nu I)$ solutions of (4.1) are a linear combination of $A$ and $B$. For an isotropic permeability, $\mu(\text{no dynamo action})$. For an isotropic permeability, $\mu = 0$, (3.12) and (3.13) are identical to the equations derived in Plunian & Alboussi`ere (2020).

4. Dynamo threshold

4.1. General form of the solutions

Looking for non-oscillating solutions, the dynamo threshold then corresponds to $\gamma = 0$. Thus, taking $\gamma = 0$ in (3.12) and (3.13), it can be shown (Appendix C) that

$$(D_{k\mu} \circ D_{k\sigma})(A) = (D_{k\sigma} \circ D_{k\mu})(B) = 0,$$

(4.1)

where

$$k_{\sigma} = k \left( \frac{1 + \sigma}{1 + \sigma s^2} \right)^{1/2}, \quad k_{\mu} = k \left( \frac{1 + \mu}{1 + \mu s^2} \right)^{1/2}.$$  

(4.2)

We note that the two operators $D_{k\sigma}$ and $D_{k\mu}$ are commutative. Therefore in (4.1) we can apply the two operators in the order we want, $D_{k\mu} \circ D_{k\sigma}$ or $D_{k\sigma} \circ D_{k\mu}$, to both $A$ and $B$. The set of functions $X(r)$, satisfying the fourth-order differential equation $(D_{k\mu} \circ D_{k\sigma})(X) = 0$, is a vector space of dimension 4. Now, we know that, whatever $\nu$, the solutions of $D_{\nu}(X) = 0$ are a linear combination of $I_1(\nu r)$ and $K_1(\nu r)$, where $I_1$ and $K_1$ are modified Bessel functions of first and second kind, of order 1. Therefore the solutions of (4.1) are a linear combination of $I_1(k_{\sigma} r)$, $K_1(k_{\sigma} r)$, $I_1(k_{\mu} r)$ and $K_1(k_{\mu} r)$.

Looking for $A$ in the form

$$A = \alpha_{\sigma} I_1(k_{\sigma} r) + \beta_{\sigma} K_1(k_{\sigma} r) + \alpha_{\mu} I_1(k_{\mu} r) + \beta_{\mu} K_1(k_{\mu} r),$$

(4.3)

and specifying that $A$ must be finite at $r = 0$ and that $\lim_{r \to \infty} A = 0$, leads to

$$A = \begin{cases} 
    r < 1, & \alpha_{\sigma} I_1(k_{\sigma} r) + \alpha_{\mu} I_1(k_{\mu} r) \\
    r > 1, & \beta_{\sigma} K_1(k_{\sigma} r) + \beta_{\mu} K_1(k_{\mu} r)
\end{cases},$$

(4.4)

where $\alpha_{\sigma}$, $\beta_{\sigma}$, $\alpha_{\mu}$ and $\beta_{\mu}$ are free parameters that will be constrained by additional boundary conditions at $r = 1$. Replacing (4.4) in (3.12) for $\gamma = 0$ leads to the following expression for $B$

$$B = \begin{cases} 
    r < 1, & \frac{ick}{s} \left( \alpha_{\sigma} I_1(k_{\sigma} r) + \frac{\mu s^2}{1 + \mu s^2} \alpha_{\mu} I_1(k_{\mu} r) \right) \\
    r > 1, & \frac{ick}{s} \left( \beta_{\sigma} K_1(k_{\sigma} r) + \frac{\mu s^2}{1 + \mu s^2} \beta_{\mu} K_1(k_{\mu} r) \right)
\end{cases},$$

(4.5)

the derivation of which being given in Appendix D.

4.2. Boundary conditions at $r = 1$

From the Maxwell equations and Green-Ostrogradski and Stokes theorems, the radial component of $B$ and the tangential components of $H = [\mu_{ij}]^{-1} B$ must be continuous at $r = 1$. Taking the expression of $B$ and $H$ given in (3.11) and (B.1), these continuity conditions can be written in terms of $A$ and $B$ as

$$A(r = 1^-) = A(r = 1^+),$$

(4.6)

$$B(r = 1^-) = B(r = 1^+),$$

(4.7)

$$\partial_r A(r = 1^-) = \partial_r A(r = 1^+).$$

(4.8)
Taking $A$ and $B$ given in (4.4) and (4.5) and replacing them in (4.6), (4.7) and (4.8) leads to (Appendix F)

\[
\alpha_\sigma I_1(k_\sigma) - \beta_\sigma K_1(k_\sigma) = 0 \quad (4.9)
\]
\[
\alpha_\mu I_1(k_\mu) - \beta_\mu K_1(k_\mu) = 0 \quad (4.10)
\]
\[
\alpha_\sigma k_\sigma I_0(k_\sigma) + \alpha_\mu k_\mu I_0(k_\mu) + \beta_\sigma k_\sigma K_0(k_\sigma) + \beta_\mu k_\mu K_0(k_\mu) = 0, \quad (4.11)
\]

where $I_0$ and $K_0$ are modified Bessel functions of first and second kind, of order 0. It is convenient to introduce the parameters $\lambda_\sigma = \alpha_\sigma I_1(k_\sigma)k/s$ and $\lambda_\mu = \alpha_\mu I_1(k_\mu)k/s$. Then, using (4.9) and (4.10), we can rewrite $A$ and $B$ in the following form:

\[
i kA = \begin{cases} 
   r < 1, & s \left( \frac{\lambda_\sigma I_1(k_\sigma r)}{I_1(k_\sigma)} + \frac{\lambda_\mu I_1(k_\mu r)}{I_1(k_\mu)} \right) \\
   r > 1, & s \left( \frac{\lambda_\sigma K_1(k_\sigma r)}{K_1(k_\sigma)} + \frac{\lambda_\mu K_1(k_\mu r)}{K_1(k_\mu)} \right)
\end{cases} \quad (4.12)
\]

\[
B = \begin{cases} 
   r < 1, & c \left( \frac{\lambda_\sigma I_1(k_\sigma r)}{I_1(k_\sigma)} + \frac{\mu s^2}{1 + \mu s^2} \frac{\lambda_\mu I_1(k_\mu r)}{I_1(k_\mu)} \right) \\
   r > 1, & c \left( \frac{\lambda_\sigma K_1(k_\sigma r)}{K_1(k_\sigma)} + \frac{\mu s^2}{1 + \mu s^2} \frac{\lambda_\mu K_1(k_\mu r)}{K_1(k_\mu)} \right)
\end{cases} \quad (4.13)
\]

The continuity of $\partial_r A$ at $r = 1$, given by (4.11), then leads to the following identity between $\lambda_\sigma$ and $\lambda_\mu$

\[
\lambda_\sigma \Gamma(k_\sigma) + \lambda_\mu \Gamma(k_\mu) = 0, \quad (4.14)
\]

with

\[
\Gamma(x) = x \left( \frac{I_0(x)}{I_1(x)} + \frac{K_0(x)}{K_1(x)} \right) \equiv (I_1(x)K_1(x))^{-1}, \quad (4.15)
\]

the last equality coming from the Wronskian relation

\[
I_m(x)K_{m+1}(x) + I_{m+1}(x)K_m(x) = 1/x. \quad (4.16)
\]

In figure 2 the eigenmodes $i kA$ and $B$ are plotted versus $r$ for $\lambda_\sigma = \Gamma(k_\sigma)$ and $\lambda_\mu = -\Gamma(k_\sigma)$ such that (4.14) is satisfied.

Finally, the tangential components $E_\theta$ and $E_z$ of the electric field

\[
E = -U \times B + [\sigma_{ij}]^{-1}J \quad (4.17)
\]

have to be continuous at $r = 1$. The expression of the current density $J$, which is derived in Appendix F, is given by

\[
J_r = -i c k \lambda_\sigma \begin{cases} 
   r < 1, & I_1(k_\sigma r)/I_1(k_\sigma) \\
   r > 1, & K_1(k_\sigma r)/K_1(k_\sigma)
\end{cases} \quad (4.18)
\]

\[
J_\theta = -\frac{\sigma sc}{1 + \sigma sc^2} J_r, \quad (4.19)
\]

\[
J_z = c k \lambda_\sigma \begin{cases} 
   r < 1, & I_0(k_\sigma r)/I_1(k_\sigma) \\
   r > 1, & -K_0(k_\sigma r)/K_1(k_\sigma)
\end{cases} \quad (4.20)
\]

where the coefficient $\exp(ikz)$ has been dropped for convenience.

From (3.7), (3.9) and (4.19), we find that $E_\theta = 0$, which is in agreement with
Dynamo action with anisotropic conductivity and permeability

Figure 2. Eigenmodes \( i k A \) (dashed lines) and \( B \) (solid lines) versus \( r \), for \( \sigma = 10^6, k = 1.1, \alpha = 0.16 \pi, \lambda_\sigma = \Gamma(k_\mu), \lambda_\mu = -\Gamma(k_\sigma) \) and for \( \mu \in \{-0.99, 0, 0.5\} \).

axisymmetric solutions. Indeed, Maxwell equation (3.3) taken at the threshold implies \( \nabla \times \mathbf{E} = 0 \). Applying the Stokes theorem to the integral of \( \nabla \times \mathbf{E} \) on a disc of radius \( r \), and assuming axisymmetry, then leads to \( \mathbf{E}_\theta(r) = 0. \)

The continuity of \( \mathbf{E}_z \) implies the following identity:

\[
(J_z + r \Omega B_r)(r = 1^-) = J_z(r = 1^+). \tag{4.21}
\]

Replacing (4.12) and (4.20) in (4.21), and using (4.14), leads to the dynamo threshold

\[
\Omega^c = \frac{C}{s} \left( I_1(k_\sigma)K_1(k_\sigma) - I_1(k_\mu)K_1(k_\mu) \right)^{-1}. \tag{4.22}
\]

5. Analysis of the results

5.1. Dispersion relation

A striking consequence of (4.22) is that \( \Omega^c(\sigma, \mu) \) is antisymmetric, satisfying

\[
\Omega^c(\sigma, \mu) = -\Omega^c(\mu, \sigma). \tag{5.1}
\]

In addition for identical anisotropies of conductivity and permeability, \( \mu = \sigma \), the threshold is infinite, leading to the impossibility of an axisymmetric dynamo,

\[
\lim_{|\sigma - \mu| \to 0} |\Omega^c(\sigma, \mu)| \to +\infty. \tag{5.2}
\]

This is illustrated in figure 3 in which the curves of a few isovalues of \( \Omega^c \) are plotted versus \( k_\sigma \) and \( k_\mu \). In particular, having both \( \sigma \gg 1 \) and \( \mu \gg 1 \) is detrimental for dynamo action, as in this case, from (4.2), \( k_\sigma \approx k_\mu \approx k/s. \)

The antisymmetry property (5.1) of \( \Omega^c(\sigma, \mu) \) can also be derived directly from the set
Figure 3. Isovalues of $\Omega^c \in \{\pm 5, \pm 10, \pm 20, \pm 40, \pm 100\}$ in the $(k_\sigma, k_\mu)$ map, for $\alpha = 0.16\pi$. The diagonal $k_\sigma = k_\mu$ corresponds to $\Omega^c \to \pm \infty$.

Figure 4. Curves of the dynamo threshold $\Omega^c$ versus $k$, for $\mu = 0$, $\alpha = 0.16\pi$ and $\sigma \in \{-0.99, -0.8, -0.6, -0.5, 1, 2, 4, +\infty\}$.
Figure 5. Curves of the dynamo threshold $\Omega^c$ versus $k$, for $\sigma = 10^5$, $\alpha = 0.16\pi$ and $\mu \in \{-0.99, -0.9, -0.5, 0, 1, 2, 5\}$.

of equations (3.12-3.13) taken for $\gamma = 0$, the boundary conditions (4.6-4.8) and (4.21), without deriving explicitly the expressions of $A$ and $B$. This is shown in Appendix G.

Alternatively, changing $\alpha$ to $-\alpha$ in (4.22) also changes $\Omega^c$ to $-\Omega^c$. This can be also derived directly from (3.12-3.13), taken for $\gamma = 0$, the boundary conditions (4.6-4.8), and (4.21), by changing $A$ to $-A$ (or $B$ to $-B$).

We check that for an isotropic permeability, $\mu = 0$, $\Omega^c$ is the same as that given in Plunian & Alboussières (2020). In figure 4 the curves of the dynamo threshold $\Omega^c$ versus $k$ are plotted for $\mu = 0$ (isotropic magnetic permeability), $\alpha = 0.16\pi$ and different values of $\sigma$. The negative values of $\sigma$ correspond to an electrical conductivity that is the highest in the direction parallel to $q$.

In figure 5 the curves of the dynamo threshold $\Omega^c$ versus $k$ are plotted for $\sigma = 10^5$, $\alpha = 0.16\pi$ and different values of $\mu$. For $\mu = 0$, the minimum value of $|\Omega^c|$ is obtained for $k = 1.1$ and $\alpha = 0.16\pi$, and is equal to $\min_{k,\alpha} |\Omega^c| = 14.61$ (Plunian & Alboussières 2020). For positive values of $\mu$, $|\Omega^c|$ increases with $\mu$, showing the detrimental effect of having both a high $\sigma$ and a high $\mu$. For negative values of $\mu$, $|\Omega^c|$ decreases with $|\mu|$, showing that the dynamo effect is favoured if the permeability is higher in the direction parallel to $q$.

For $s = 0$ (radial $q$) or $c = 0$ (azimuthal $q$), the dynamo is impossible. This is obvious for $s = 0$ as the threshold given by (4.22) is infinite. For $c = 0$, (4.13) implies that $B = 0$. In addition, as $s^2 = 1$, (4.2) implies that $k_\sigma = k_\mu = k$. Then, from (4.12) and (4.14), we find that $A = 0$.

5.2. Current density

Concerning the current density $\mathbf{J}$, given at the threshold by (4.18-4.20), we note that it only depends on $\sigma$, and not on $\mu$. In other words, taking an anisotropic magnetic
permeability \( \mu \neq 0 \) does not change the geometry of the current density with respect to the isotropic case \( \mu = 0 \).

For an isotropic conductivity \( \sigma = 0 \), we find that \( \mathbf{J}_\theta = 0 \). This corresponds to the neutral point argument of Cowling (1934), after which a toroidal current density cannot be produced if axisymmetry is assumed. However, and although such a neutral point argument is satisfied for \( \sigma = 0 \), this does not exclude the possibility of dynamo action for an anisotropic magnetic permeability \( \mu \neq 0 \).

From (4.19), we note that the projection in the \((r,\theta)\) plane of the current density \( \mathbf{J} \) describes spiralling trajectories. In the limit \( \sigma \to +\infty \), we find that \( \mathbf{J} \cdot \mathbf{q} = 0 \).

### 5.3. Magnetic induction

From the expression of \( \mathbf{B} \) given in (3.11), and applying (4.12), (4.13) and (E.5), leads to the following expressions for the magnetic induction components

\[
\mathbf{B}_r = -s \begin{cases} 
  r < 1, & \lambda_\sigma I_1(k_\sigma r) + \lambda_\mu I_0(k_\mu r) \\
  r > 1, & \lambda_\sigma K_1(k_\sigma r) + \lambda_\mu K_0(k_\mu r)
\end{cases},
\]

(5.3)

\[
\mathbf{B}_\theta = c \begin{cases} 
  r < 1, & \lambda_\sigma I_1(k_\sigma r) + \lambda_\mu \left( \frac{\mu s^2}{1 + \mu s^2} \right) I_0(k_\mu r) \\
  r > 1, & \lambda_\sigma K_1(k_\sigma r) + \lambda_\mu \left( \frac{\mu s^2}{1 + \mu s^2} \right) K_0(k_\mu r)
\end{cases},
\]

(5.4)

\[
\mathbf{B}_z = -\frac{is}{k} \begin{cases} 
  r < 1, & \lambda_\sigma k_\sigma I_0(k_\sigma r) + \lambda_\mu k_\mu I_1(k_\mu r) \\
  r > 1, & -\lambda_\sigma k_\sigma K_0(k_\sigma r) - \lambda_\mu k_\mu K_1(k_\mu r)
\end{cases},
\]

(5.5)

where, again, the coefficient \( \exp(ikz) \) has been dropped for convenience. In contrast to \( \mathbf{J} \), the induction field depends not only on \( \sigma \), but also on \( \mu \), implying the following remarks.

In the case of identical anisotropic conductivity and permeability, \( \sigma = \mu \), as mentioned earlier the dynamo is impossible. From (4.2) and (4.14) we have \( k_\sigma = k_\mu \) and \( \lambda_\sigma + \lambda_\mu = 0 \), implying that \( \mathbf{B}_r = \mathbf{B}_z = 0 \). In that case the induction field \( \mathbf{B} \) is then purely toroidal. This is in agreement with the antidynamo theorem of Kaiser et al. (1994), after which an invisible dynamo, with a purely toroidal magnetic field, is impossible.

In the limit \( \mu \to \infty \), from (5.3) and (5.4) we have \( c\mathbf{B}_r = -s\mathbf{B}_\theta \), implying that \( \mathbf{B} \cdot \mathbf{q} = 0 \). The projection in the \((r,\theta)\) plane of the induction field \( \mathbf{B} \) thus describes spiralling trajectories perpendicular to \( \mathbf{q} \).

In figure 6 the current lines of \( \mathbf{B} \) and \( \mathbf{J} \) are plotted in the horizontal plane for different values of \((\sigma, \mu)\). In figures 6a, 6b and 6c, \( \sigma = 10^5 \) and \( \mu \in \{-0.99; 0; 5\} \). The current lines of \( \mathbf{J} \) are identical because, as previously seen, \( \mathbf{J} \) does not depend on \( \mu \). From 6a to 6c, increasing \( \mu \) has the effect of distorting the \( \mathbf{B} \) current lines in the outer cylinder, such that the current lines of \( \mathbf{B} \) reach the same curvature as the current lines of \( \mathbf{J} \), which eventually is detrimental to dynamo action. In figures 6d, 6e and 6f, \( \mu = 10^5 \) and \( \sigma \in \{-0.99; 0; 10\} \). From 6d to 6f, increasing \( \sigma \) has the effect of distorting the \( \mathbf{J} \) current lines in both inner and outer cylinders, such that the current lines of \( \mathbf{J} \) reach the same curvature direction as the current lines of \( \mathbf{B} \), which ultimately is again detrimental to the dynamo action. We note that the \( \mathbf{J} \) current lines in figures 6a, 6b and 6c: and the \( \mathbf{B} \)
Figure 6. Current lines of $B$ (solid lines) and $J$ (dashed lines) in the horizontal plane for $\alpha = 0.16\pi$, $k = 1.1$, and for (a) $(\sigma, \mu) = (10^5, -0.99)$, (b) $(\sigma, \mu) = (10^7, 0)$, (c) $(\sigma, \mu) = (10^5, 5)$, (d) $(\sigma, \mu) = (-0.99, 10^5)$, (e) $(\sigma, \mu) = (0, 10^5)$, (f) $(\sigma, \mu) = (10, 10^5)$.

Current lines in figures 6d, 6e and 6f are identical. This is because $\sigma \gg 1$ in figures 6a, 6b and 6c, implying $J \cdot q \approx 0$, and $\mu \gg 1$ in figures 6d, 6e and 6f, implying $B \cdot q \approx 0$.

6. Dynamo mechanism

The set of equations (3.12-3.13) can be rewritten in terms of $B_r$ and $B_\theta$ as

$$\gamma B_r = c_\sigma (\sigma - \mu) k^2 B_\theta - (1 + \sigma s^2) D_{\tilde{k}^{\sigma\mu}} (B_r)$$  \hspace{1cm} (6.1)

$$\gamma B_\theta = c_\sigma (\sigma - \mu) D_k (B_r) - (1 + \mu s^2) D_{\tilde{k}^{\mu\sigma}} (B_\theta),$$  \hspace{1cm} (6.2)

with

$$\tilde{k}^{\sigma\mu} = k \left( 1 + \frac{\mu c^2}{1 + \sigma s^2} \right)^{1/2}, \hspace{0.5cm} \tilde{k}^{\mu\sigma} = k \left( 1 + \frac{\sigma c^2}{1 + \mu s^2} \right)^{1/2}.$$  \hspace{1cm} (6.3)

On the right hand side of each equation (6.1) and (6.2), the first term is a source term for the dynamo effect, while the second term is a decay term. In (6.1), resp. (6.2), the term...
**7. Conclusions**

For an anisotropic electrical conductivity ($\sigma^\perp \neq \sigma^\parallel$) conjugated to an anisotropic magnetic permeability ($\mu^\perp \neq \mu^\parallel$), we could think that maximizing the ratio $\sigma^\perp / \sigma^\parallel \gg 1$ and $\mu^\perp / \mu^\parallel \gg 1$ is in fact highly detrimental to the dynamo effect, these two conditions having the effect of aligning the current lines of respectively the current density $J$ and magnetic induction $B$ in the same direction $q^\perp$. In contrast, having $\sigma^\perp / \sigma^\parallel \gg 1$ and $\mu^\perp / \mu^\parallel = 1$, or $\sigma^\perp / \sigma^\parallel = 1$ and $\mu^\perp / \mu^\parallel \gg 1$ leads to the same dynamo threshold $|\Omega^c| = 14.61$, for $k = 1.1$ and $\alpha = 0.16\pi$.

As an application let us consider an experimental demonstration of the dynamo effect based on such conductivity and permeability spiral anisotropy, with differential rotation between two cylinders, as sketched in figure 4. An anisotropic conductivity, resp. permeability, can be manufactured by alternating thin layers of two materials with different conductivities, resp. permeabilities. Although the resulting medium is no longer axisymmetric, our model is still a good approximation of such an experiment. To realize the first case $\sigma^\perp / \sigma^\parallel \gg 1$ and $\mu^\perp / \mu^\parallel = 1$, we can alternate spiral layers of a high electrical conductivity material, e.g. copper, and a material which is electrically insulating, e.g. epoxy resin, both having a relative magnetic permeability equal to unity. To realize the second case $\sigma^\perp / \sigma^\parallel = 1$ and $\mu^\perp / \mu^\parallel \gg 1$, we can alternate spiral layers of a high magnetic permeability material, e.g. $\mu$-metal (permalloy), and a material with a relative magnetic permeability equal to unity, e.g. stainless steel, both having approximately the same electrical conductivity. The current lines of $B$ and $J$ of these two cases are illustrated in figure 6(b) and 6(e). For the second case, a crucial issue will be to guarantee a good electrical contact between both materials, $\mu$-metal and stainless steel. Indeed, if this is
not the case, this would correspond to having $\sigma^\perp/\sigma^\parallel \gg 1$ and $\mu^\perp/\mu^\parallel \gg 1$ which, again, would be highly detrimental to the dynamo effect.

In the case of an isotropic electrical conductivity, $\sigma^\perp/\sigma^\parallel = 1$, and as illustrated in figure 6e, the azimuthal current density is null, $J_\theta = 0$, which is in agreement with the neutral point argument of Cowling. As $J = \nabla \times \mathbf{H}$, this implies that the circulation of the poloidal component of $\mathbf{H}$ on a closed current line is zero (Cowling 1934). However, as shown in (B 1), in the case of an anisotropic magnetic permeability this does not imply that the poloidal component of $\mathbf{B}$ is zero. Therefore, although the neutral point argument of Cowling still holds, it does not imply the impossibility of a dynamo effect.

Acknowledgements

We thank R. Deguen for fruitful discussions on Earth’s inner core anisotropy.

Appendix A. Derivation of $\nabla \times (\mathbf{U} \times \mathbf{B}) = 0$

Assuming axisymmetry ($\partial_\theta = 0$), the curl of the cross product of $\mathbf{U} = r\Omega\mathbf{e}_\theta$ and $\mathbf{B} = (B_r, B_\theta, B_z)$ is given by $\nabla \times (\mathbf{U} \times \mathbf{B}) = (\partial_z(r\Omega B_z) + \partial_r(r\Omega B_r)) \mathbf{e}_\theta$. Assuming that $\Omega$ is constant in space and using the solenoidality of $\mathbf{B}$, $\nabla \cdot \mathbf{B} = 0$, leads to $\nabla \times (\mathbf{U} \times \mathbf{B}) = 0$.

Appendix B. Derivation of (3.12) and (3.13)

The product of $[\mu_{ij}]^{-1} = \begin{pmatrix} 1 + \mu c^2 & \mu c s & 0 \\ \mu c s & 1 + \mu s^2 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ given by (3.8), and the induction field $\mathbf{B} = \begin{pmatrix} -ikA \\ B \\ \frac{1}{r}\partial_r(rA) \end{pmatrix} \exp(\gamma t + ikz)$ given by (3.11), leads to the magnetic field

$$\mathbf{H} = [\mu_{ij}]^{-1} \mathbf{B} = \begin{pmatrix} -ik(1 + \mu c^2)A + \mu c s B \\ -ik\mu c s A + (1 + \mu s^2)B \\ \frac{1}{r}\partial_r(rA) \end{pmatrix},$$

(B 1)

where, from now, the exponential term is dropped for convenience. Assuming axisymmetry, the curl of $\mathbf{H}$ takes the form $\nabla \times \mathbf{H} = \begin{pmatrix} i k H_\theta - \partial_r H_z \\ i k H_\theta - \partial_r(rH_\theta) \\ \frac{1}{r}\partial_r(rH_\theta) \end{pmatrix}$, leading to the current density

$$\mathbf{J} = \nabla \times \mathbf{H} = \begin{pmatrix} -k^2 \mu c s A - ik(1 + \mu s^2)B \\ D_k(A) + \mu c s k^2 A + i\mu c s k B \\ -i\mu c s k \frac{1}{r}\partial_r(rA) + (1 + \mu s^2)\frac{1}{r}\partial_r(rB) \end{pmatrix},$$

(B 2)

where $D_\nu(X) = \nu^2 X - \partial_r \left( \frac{1}{r}\partial_r(rX) \right)$. The product of $[\sigma_{ij}]^{-1} = \begin{pmatrix} 1 + \sigma c^2 & \sigma c s & 0 \\ \sigma c s & 1 + \sigma s^2 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ given by (3.7), and $\mathbf{J}$ given by (B 2), leads to

$$[\sigma_{ij}]^{-1} \mathbf{J} = \begin{pmatrix} -k^2 \mu c s A + \sigma c s D_k(A) - ik(1 + \sigma c^2 + \mu s^2)B \\ \mu c s k^2 A + (1 + \sigma s^2)D_k(A) - i\sigma c s k(\sigma - \mu)B \\ -i\mu c s k \frac{1}{r}\partial_r(rA) + (1 + \mu s^2)\frac{1}{r}\partial_r(rB) \end{pmatrix}. $$

(B 3)
Taking the curl leads to $\nabla \times [\sigma_{ij}]^{-1} \mathbf{J} = \left( \begin{array}{c} -ikF \\ G \\ \frac{1}{r} \partial_r(rF) \end{array} \right)$, with

$$F = \mu c^2 k^2 A + (1 + \sigma s^2) D_k(A) - i c k s (\sigma - \mu) B,$$

$$G = i c k s (\sigma - \mu) D_k(A) + \sigma c^2 k^2 B + (1 + \mu s^2) D_k(B).$$

As $\nabla \times (\mathbf{U} \times \mathbf{B}) = 0$, the induction equation (3.6) is reduced to $\partial_t \mathbf{B} = -\nabla \times [\sigma_{ij}]^{-1} \mathbf{J}$, leading to

$$\gamma A = -F,$$

$$\gamma B = -G,$$

$$\frac{\gamma}{r} \partial_r(rA) = -\frac{1}{r} \partial_r(rF),$$

and then to (3.12) and (3.13).

**Appendix C. Derivation of the fourth-order differential equation**

(4.1) satisfied by $A$ and $B$ at the dynamo threshold

Replacing $\gamma = 0$ in (3.12) and (3.13) leads to the following system

$$(1 + \sigma s^2) D_k(A) + \mu c^2 k^2 A = i c k s (\sigma - \mu) B,$$  \hspace{1cm} (C 1)

$$(1 + \mu s^2) D_k(B) + \sigma c^2 k^2 B = -i c k s (\sigma - \mu) D_k(A),$$  \hspace{1cm} (C 2)

where, again, $D_k(X) = \nu^2 X - \partial_r \left( \frac{1}{r} \partial_r(rX) \right)$.

It is straightforward to show that

$$(1 + \sigma s^2) D_k(X) = (1 + \sigma s^2) D_{k,\sigma}(X) - \sigma c^2 k^2 X,$$

$$(1 + \mu s^2) D_k(X) = (1 + \mu s^2) D_{k,\mu}(X) - \mu c^2 k^2 X,$$  \hspace{1cm} (C 3, C 4)

where $k_{\sigma}$ and $k_{\mu}$ are defined in (4.2) and that we rewrite here for convenience

$$k_{\sigma} = k \left( \frac{1 + \sigma}{1 + \sigma s^2} \right)^{1/2}, \quad k_{\mu} = k \left( \frac{1 + \mu}{1 + \mu s^2} \right)^{1/2}.$$

Using (C 3) and (C 4) in (C 1) and (C 2) then leads to

$$(1 + \sigma s^2) D_{k,\sigma}(A) = c k (\sigma - \mu) (c k A + i s B),$$  \hspace{1cm} (C 5)

$$(1 + \mu s^2) D_{k,\mu}(B) = -c k (\sigma - \mu) (c k B + i s D_k(A)).$$  \hspace{1cm} (C 6)

Then to obtain (4.1), we need to demonstrate that $D_{k,\sigma}(c k A + i s B) = 0$ and $D_{k,\mu}(c k B + i s D_k(A)) = 0$. For that, we rewrite (C 1) and (C 2) as

$$D_k(A) = \sigma \left( -s^2 D_k(A) + i c k s B \right) - \mu \left( c^2 k^2 A + i c k s B \right),$$

$$D_k(B) = -\sigma \left( c^2 k^2 B + i c k s D_k(A) \right) + \mu D_k \left( -s^2 B + i c k s A \right).$$  \hspace{1cm} (C 7, C 8)

Multiplying (C 7) by $c k$, (C 8) by $i s$, and adding both quantities leads to

$$(1 + \mu s^2) D_k(c k A + i s B) = -\mu c^2 k^2 (c k A + i s B),$$  \hspace{1cm} (C 9)

which, from (C 4) with $X = c k A + i s B$, is equivalent to

$$D_{k,\mu}(c k A + i s B) = 0.$$  \hspace{1cm} (C 10)

Applying (C 10) to (C 5) then leads to

$$\left( D_{k,\mu} \circ D_{k,\sigma} \right)(A) = 0.$$  \hspace{1cm} (C 11)
Dynamo action with anisotropic conductivity and permeability

Taking $D_k$ of (C7) multiplied by is on the one hand, and (C8) multiplied by $ck$ on the other hand, and adding both quantities leads to

$$ (1 + \sigma s^2)D_k(ckB + isD_k(A)) = -\sigma c^2 k^2 (ckB + isD_k(A)), \quad (C12) $$

which, from (C3) with $X = ckB + isD_k(A)$, is equivalent to

$$ D_{ks} (ckB + isD_k(A)) = 0. \quad (C13) $$

Applying (C13) to (C6) leads to

$$ (D_{k\sigma} \circ D_{k\nu})(B) = 0, \quad (C14) $$

which, together with (C11), corresponds to (4.1).

Appendix D. Derivation of $B$, given in (4.5), at the dynamo threshold

Starting from (4.4), which we rewrite here as

$$ A = \begin{cases} r < 1, & \alpha_\sigma I_1(k_\sigma r) + \alpha_\mu I_1(k_\mu r) \\ r > 1, & \beta_\sigma K_1(k_\sigma r) + \beta_\mu K_1(k_\mu r) \end{cases}, $$

we will derive $B$ from (3.12), which we write here for $A$ values

$$ B = ((1 + \sigma s^2)D_k(A) + \mu c^2 k^2 A) / (icsk(\sigma - \mu)). \quad (D1) $$

Using the relations (C3) and (C4), and knowing that, whatever $\nu$, $D_\nu(I_1(k_\nu r)) = D_\nu(K_1(k_\nu r)) = 0$ we find that

$$ D_k(A) = \begin{cases} r < 1, & -\frac{\sigma c^2 k^2}{1 + \sigma s^2} \alpha_\sigma I_1(k_\sigma r) - \frac{\mu c^2 k^2}{1 + \mu s^2} \alpha_\mu I_1(k_\mu r) \\ r > 1, & -\frac{\sigma c^2 k^2}{1 + \sigma s^2} \beta_\sigma K_1(k_\sigma r) - \frac{\mu c^2 k^2}{1 + \mu s^2} \beta_\mu K_1(k_\mu r) \end{cases}. \quad (D2) $$

Then, replacing in (D1) the expressions of $A$ and $D_k(A)$ given by (4.4) and (D2) leads to the following expression for $B$, which is also given in (4.5):

$$ B = \begin{cases} r < 1, & -\frac{ick}{s} \left( \alpha_\sigma I_1(k_\sigma r) + \frac{\mu s^2}{1 + \mu s^2} \alpha_\mu I_1(k_\mu r) \right) \\ r > 1, & -\frac{ick}{s} \left( \beta_\sigma K_1(k_\sigma r) + \frac{\mu s^2}{1 + \mu s^2} \beta_\mu K_1(k_\mu r) \right) \end{cases}. $$

Appendix E. Derivation of the boundary conditions (4.9), (4.10) and (4.11) at the dynamo threshold

The continuity of $A$ and $B$ at $r = 1$, taken from their expressions (4.4) and (4.5), takes the following form:

$$ \alpha_\sigma I_1(k_\sigma) + \alpha_\mu I_1(k_\mu) = \beta_\sigma K_1(k_\sigma) + \beta_\mu K_1(k_\mu) \quad (E1) $$

$$ \alpha_\sigma I_1(k_\sigma) + \frac{\mu s^2}{1 + \mu s^2} \alpha_\mu I_1(k_\mu) = \beta_\sigma K_1(k_\sigma) + \frac{\mu s^2}{1 + \mu s^2} \beta_\mu K_1(k_\mu) \quad (E2) $$

leading to (4.9) and (4.10), which we rewrite here as

$$ \alpha_\sigma I_1(k_\sigma) - \beta_\sigma K_1(k_\sigma) = 0 $$

$$ \alpha_\mu I_1(k_\mu) - \beta_\mu K_1(k_\mu) = 0. $$
To write the continuity of $\partial_r A$ at $r = 1$ we first need to calculate the expression of $\partial_r A$ at any $r$. Using the following relations satisfied whatever $\nu$:

$$\partial_r (I_1(\nu r)) = \nu I_0(\nu r) - \frac{1}{r} I_1(\nu r), \quad (E\, 3)$$
$$\partial_r (K_1(\nu r)) = -\nu K_0(\nu r) - \frac{1}{r} K_1(\nu r), \quad (E\, 4)$$

the expression of $\partial_r A$ is obtained by deriving (4.4):

$$\partial_r A = \begin{cases} r < 1, & \alpha_\sigma \left( k_\sigma I_0(k_\sigma r) - \frac{1}{r} I_1(k_\sigma r) \right) + \alpha_\mu \left( k_\mu I_0(k_\mu r) - \frac{1}{r} I_1(k_\mu r) \right) \\ r > 1, & \beta_\sigma \left( -k_\sigma K_0(k_\sigma r) - \frac{1}{r} K_1(k_\sigma r) \right) + \beta_\mu \left( -k_\mu K_0(k_\mu r) - \frac{1}{r} K_1(k_\mu r) \right) \end{cases} \quad (E\, 5)$$

Then, the continuity of $\partial_r A$ at $r = 1$ leads to

$$\alpha_\sigma (k_\sigma I_0(k_\sigma) - I_1(k_\sigma)) + \alpha_\mu (k_\mu I_0(k_\mu) - I_1(k_\mu)) = \beta_\sigma (-k_\sigma K_0(k_\sigma) - K_1(k_\sigma)) + \beta_\mu (-k_\mu K_0(k_\mu) - K_1(k_\mu)). \quad (E\, 6)$$

Then, taking advantage of (4.9) and (4.10), (E\, 6) can be simplified to

$$\alpha_\sigma k_\sigma I_0(k_\sigma) + \alpha_\mu k_\mu I_0(k_\mu) + \beta_\sigma k_\sigma K_0(k_\sigma) + \beta_\mu k_\mu K_0(k_\mu) = 0,$$

which is (4.11).

**Appendix F. Derivation of the current density $J$ at the dynamo threshold**

We rewrite the current density $J$ which is given in (B2) as

$$J = \nabla \times H = \begin{pmatrix} -ik\phi \\ D_k(A) + \mu c^2 k^2 A + i\mu cs k B \\ \frac{1}{r} \partial_r (r\phi) \end{pmatrix},$$

with $\phi = -ik\mu cs A + (1 + \mu s^2) B$. At the dynamo threshold $A$ and $B$ can be replaced by their expressions (4.4) and (4.5), leading to

$$\phi = \begin{cases} r < 1, & \frac{ick}{s} \alpha_\sigma I_1(k_\sigma r) \\ r > 1, & \frac{ick}{s} \beta_\sigma K_1(k_\sigma r) \end{cases} \quad (F\, 1)$$

Using the relations (E\, 3) and (E\, 4) leads to

$$\frac{1}{r} \partial_r (r\phi) = \begin{cases} r < 1, & \frac{ick}{s} \alpha_\sigma k_\sigma I_0(k_\sigma r) \\ r > 1, & -\frac{ick}{s} \beta_\sigma k_\sigma K_0(k_\sigma r) \end{cases} \quad (F\, 2)$$

Using (C4), we find that

$$D_k(A) + \mu c^2 k^2 A + i\mu cs k B = D_{k\mu}(A) + \frac{i\mu cs k}{1 + \mu s^2} \phi. \quad (F\, 3)$$

Then from the expression of $A$ given at the threshold by (4.4), we have

$$D_{k\mu}(A) = \begin{cases} r < 1, & \alpha_\sigma D_{k\mu}(I_1(k_\sigma r)) \\ r > 1, & \beta_\sigma D_{k\mu}(K_1(k_\sigma r)) \end{cases} \quad (F\, 4)$$
Combining (C3) and (C4) we have

\[ D_{k_\nu}(X) = D_{k_\sigma}(X) + c^2 k^2 \left( \frac{\mu}{1 + \mu s^2} - \frac{\sigma}{1 + \sigma s^2} \right) X, \]  

(F 5)

implying that

\[ D_{k_\nu}(A) = \begin{cases} 
  r < 1, & \alpha_\sigma c^2 k^2 \left( \frac{\mu}{1 + \mu s^2} - \frac{\sigma}{1 + \sigma s^2} \right) I_1(k_\sigma r) \\
  r > 1, & \beta_\sigma c^2 k^2 \left( \frac{\mu}{1 + \mu s^2} - \frac{\sigma}{1 + \sigma s^2} \right) K_1(k_\sigma r)
\end{cases}, \]  

(F 6)

where, again, we used the property that, whatever \( \nu \), \( D_\nu(I_1(k_\nu r)) = D_\nu(K_1(k_\nu r)) = 0 \). Therefore we find that

\[ D_{k_\nu}(A) + \frac{i \mu c s k}{1 + \mu s^2} \phi = \begin{cases} 
  r < 1, & -\frac{\sigma c^2 k^2}{1 + \sigma s^2} \alpha_\sigma I_1(k_\sigma r) \\
  r > 1, & -\frac{\sigma c^2 k^2}{1 + \sigma s^2} \beta_\sigma K_1(k_\sigma r)
\end{cases}. \]  

(F 7)

Then the current density takes the following form

\[ \text{for } r < 1, \quad J = \begin{pmatrix} 
  \frac{c k^2}{s} \alpha_\sigma I_1(k_\sigma r) \\
  -\frac{s c^2 k^2}{s + \sigma s^2} \alpha_\sigma I_1(k_\sigma r) \\
  \frac{i c k}{s} \alpha_\sigma k_\sigma I_0(k_\sigma r)
\end{pmatrix}, \]  

(F 8)

\[ \text{for } r > 1, \quad J = \begin{pmatrix} 
  \frac{c k^2}{s} \beta_\sigma K_1(k_\sigma r) \\
  -\frac{s c^2 k^2}{s + \sigma s^2} \beta_\sigma K_1(k_\sigma r) \\
  \frac{i c k}{s} \beta_\sigma k_\sigma K_0(k_\sigma r)
\end{pmatrix}. \]  

(F 9)

Then, substituting \( \alpha_\sigma \) and \( \beta_\sigma \) by their expressions in terms of \( \lambda_\sigma, \alpha_\sigma = -i s \lambda_\sigma / (k I_1(k_\nu r)) \) and \( \beta_\sigma = -i s \lambda_\sigma / (k K_1(k_\nu r)) \), leads to (4.18-4.20).

**Appendix G. Derivation of the antisymmetric relation (5.1)**

Let us rewrite the set of equations (3.12-3.13) for \( \gamma = 0 \), the boundary conditions (4.6-4.8) and (4.21):

\[ (1 + \sigma s^2) D_k(A) + \mu c^2 k^2 A = i c s k (\sigma - \mu) B, \]  

(G 1)

\[ (1 + \mu s^2) D_k(B) + \sigma c^2 k^2 B = -i c s k (\sigma - \mu) D_k(A), \]  

(G 2)

\[ [A]_{r=1}^{r=1^+} = [B]_{r=1}^{r=1^+} = [\partial_r A]_{r=1}^{r=1^+} = 0, \]  

(G 3)

\[ (1 + \mu s^2) [\partial_r B]_{r=1}^{r=1^+} = -i k \Omega A(r = 1^-), \]  

(G 4)

where \( [X]_{r=1}^{r=1^+} = X(r = 1^+) - X(r = 1^-) \), and (G 4) being derived from (4.21) using (B 2). The system (G 1-G 4) is the complete system of equations leading to the dynamo threshold (4.22).

Now, defining the new variables \( A' \) and \( B' \) as

\[ A' = -\frac{1 + \sigma s^2}{1 + \mu s^2} A, \]  

(G 5)

\[ B' = B - i k \frac{c}{s} \left( \frac{1 + \sigma s^2 + \mu s^2}{1 + \sigma s^2} \right) A, \]  

(G 6)
and replacing them into (G 1-G 4) leads to

\[(1 + \mu s^2)D_k(A') + \sigma c^2 k^2 A' = icsk(\mu - \sigma)B', \quad (G 7)\]
\[(1 + \sigma s^2)D_k(B') + \mu c^2 k^2 B' = -icsk(\mu - \sigma)D_k(A'), \quad (G 8)\]

\[ [A']_r^{1-1} = [B']_r^{1-1} = [\partial_r A']_r^{1-1} = 0, \quad (G 9)\]
\[(1 + \sigma s^2)[\partial_r B']_r^{1-1} = i k \Omega A'(r = 1^-). \quad (G 10)\]

It shows that the new variables \(A'\) and \(B'\) obey to the same equations as \(A\) and \(B\), in which \(\sigma\) and \(\mu\) have been changed to \(\mu\) and \(\sigma\), and \(\Omega\) to \(-\Omega\).
