Safe Reachability Verification of Nonlinear Switched Systems via a Barrier Density

Ays¸egül Kılçım1, Özkan Karabacak1 and Rafael Wisniewski1

Abstract—We study temporal properties of dynamical systems; specifically, we strive to determine a set of initial states that leads the solutions to reach desired states avoiding a predetermined unsafe set. This property, which we call safe reachability, has been studied in literature for autonomous systems using barrier function and barrier densities [1]. In this paper, we generalize a sufficient condition for safe reachability of autonomous system to switched systems under arbitrary switching signals. The condition relies upon the existence of a common barrier density function for each subsystem. We apply the condition using the sum of squares method together with Putinar Positivstellensatz.

I. INTRODUCTION

In many control applications, one needs to ensure that a system with an initial state reaches to a desired state (reachability) avoiding some undesired states (safety). One of the widely used method for the verification of the safety and the reachability is the application of barrier functions which allows to analyze a system without knowing explicitly the solutions as done in the analysis with Lyapunov functions. To mention a few applications, barrier functions have been used for safety verification of unmanned aerial system to perform high speed in an environment with multiple obstacles [2], for model validation, i.e., checking the inconsistency of the measured data with the model [3], for detecting the faults in a system [4], for verification of safety and reachability of nonlinear autonomous systems and systems with disturbances [1], and for the computation of the reachable sets [5] (for more applications see [1], [4], [6], [7], [8], [9], [10], [11] and the references therein). As mentioned in the paper [1], one may not be able to find a barrier function to certify safety and reachability due to the fact that the solution trajectory for some initial state, which is in a negligible set - a set with measure zero, may enter an undesired set or may not reach a desired set. In [1], notions of “weak safety” and “weak reachability” are defined to indicate that the safety and reachability properties are satisfied except the set of (Lebesgue) measure zero. In the light of this, weak safe reachibility can be defined as follows: There exists a time such that for almost every initial state the solution enters a desired region without entering an undesired region. In [1], to certify the weak safety of nonlinear autonomous system barrier density is utilized. Density functions are also used for stability analysis [12], [13], [14], [15], [16], [17], [18], [19], [20], [21]. Leaning upon the results of [1], our main goal in this paper is to obtain a sufficient condition for the weak safe reachibility of nonlinear switched system under arbitrary switching.

Nonlinear switched systems appear in various applications (for instance [22] and the references therein). In particular, nonlinear switched systems with time dependent switching can be used to model switched control systems where switching is generated by an external system [23] (for more applications, see the references in [22], [23], [24]). Recently, using common and multiple Lyapunov densities, we have obtained sufficient conditions for the almost global stability of switched systems [25]. In [26], safety verification of nonlinear switched systems is studied by utilizing barrier functions and barrier densities. In contrast to [26], here, we have considered the safe reachability problem of nonlinear switched system via a common barrier density which can be seen as a generalization of the result of the paper [26].

Inspired by the common Lyapunov density approach in [25] and the dual Lyapunov analysis of weak safety and reachability in [1], we analyze the safe reachability of a nonlinear switched system. Leaning upon the existence of a common Barrier density, we present a sufficient condition for weak safe reachability under arbitrary switching.

The paper is structured as follows: In Section II, we present preliminaries about nonlinear switched systems under arbitrary switching. In Section III, we define safe reachability and weak safe reachability of a system and present a sufficient condition for the weak safe reachability of nonlinear switched systems with time-varying switching. In Section IV, we present an example by using the sum of squares algorithm to illustrate theoretical part of our paper and we present a brief summary about the usage of Sum of Squares (SoS) technique together with Putinar Positivstellensatz.

**Notation.** The following notations will be used in the remaining part of the paper.

- $m$ denotes the Lebesgue measure on $\mathbb{R}^n$, and $\mu_p(A) = \int_A \mu(x)\,dx$ denotes Lebesgue integral with respect to measure $\mu$, here we will define Lebesgue integral with respect to Lebesgue measure $m$ as $\int \,dx$.
- For a function $f : \mathbb{R}^n \to \mathbb{R}^n$, and $\nabla \cdot f$ denotes the divergence of $f$ and for a function $g : \mathbb{R}^n \to \mathbb{R}$, $\nabla g$ denotes the gradient of $g$.
- $\text{Int}(A)$, $\partial A$ and $\overline{A}$ denote the interior, the complement and the closure of a set $A$, respectively. Also, $\partial A = \overline{A} \setminus \text{Int}(A)$.

The notions “almost every” and “almost all” are used to indicate that the given property is satisfied everywhere except...
for a set with Lebesgue measure zero.

II. PRELIMINARIES

We have extended Corollary 3.11 [1] (rewritten as Proposition 1 below) to the nonlinear switched systems under arbitrary switching signals. In the next section, the conditions of the proposition will be generalized to nonlinear switched systems and reformulated. In [1], they have analyzed safety and reachability of the given sets by applying a bisection algorithm on the set of initial states, $X_0$ and SoS programming which is not computationally efficient since it requires to verify safety and reachability by solving SoS algorithm for each partition of $X_0$. In this paper, we will propose another method to verify the safety reachability which leans upon searching common barrier density via the sum of squares (SoS) programming together with Putinar positivstellensatz [27]. Specifically, SoS programming is used for determining whether a polynomial is non-negative on a compact set together with Putinar positivstellensatz is applied to determine $\phi^0_t(x)$. Specifically, SoS programming is used for determining whether a polynomial can be represented as a combination of sum of squares of polynomials. SoS programming together with Putinar positivstellensatz is applied to determine whether a polynomial is non-negative on a compact set which is defined semi-algebraically, i.e., the set is defined via polynomial inequalities.

For the sake of the completeness, let us restate Corollary 3.11 given in [1].

**Proposition 1:** [1, Corollary 3.11] Consider a system $\dot{x} = f(x)$, where $f$ is a continuously differentiable function on $\mathbb{R}^n$. Let $X$ be a bounded subset of $\mathbb{R}^n$, and $X_0 \subseteq X$ be a set with positive Lebesgue measure. Assume that a desired set $X_r \subseteq X$ and an unsafe set $X_u \subseteq X$ are given. If there exists a continuously differentiable function $\rho(x) \in \mathbb{R}^n$ satisfying

\[
\begin{align*}
\nabla \cdot (\rho f)(x) &> 0, \quad \forall x \in X_0, \quad (1a) \\
\rho(x) &\leq 0, \quad \forall x \in (\partial X \setminus \partial X_r) \cup X_u, \quad (1c)
\end{align*}
\]

then the weak safe reachability property holds; i.e. for almost every initial states $x_0 \in X_0$ the solution $x(t)$ starting at $x(0) = x_0$ satisfies, for some $T \geq 0$, $x(T) \in X_r$, $x(t) \notin X_u$, and $x(t) \in X$, for all $t \in [0, T]$.

Consider a continuous-time nonlinear switched system of the following form

\[
\dot{x}(t) = f_\sigma(x(t)), \quad \sigma \in S_{\text{nonchat}} \tag{2}
\]

where $\sigma$ is the switching signal. The switching signal, $\sigma(t) : [0, \infty) \rightarrow \{1, 2, \ldots, N\}$, is assumed to be a right continuous piece-wise constant function. The largest set for admissible switching signal is a set of switching signals which have finite number of discontinuities in a finite time interval and denoted by $S_{\text{nonchat}}$. Each system given by $\dot{x}(t) = f_p(x(t)), \quad p = 1, 2, \ldots, N$ is called the subsystem of the system (2). Assume that each subsystem $f_p : \mathbb{R}^n \rightarrow \mathbb{R}^n$, $i = 1, 2, \ldots, N$, is continuously differentiable on $\mathbb{R}^n$. Denote the constant value of the switching signal $\sigma(t)$ for $t \in [t_{i-1}, t_i]$ as $p_i$. By using these values switching signal can be defined as $\sigma(t) = \{ (\Delta_{t_1}, p_1), (\Delta_{t_2}, p_2), \ldots \}$, where $\Delta_{t_i}$ is the operation time of the subsystem $f_{p_i}$. Assume that solutions of (2) with $S_{\text{nonchat}}$ exist for all $t \in \mathbb{R}$. Denote a solution of system (2) for the switching signal $\sigma \in S_{\text{nonchat}}$ and for the initial state $x$ as $\phi_t^\sigma(x)$.

**Remark 1:** Since $f_p, \quad p = 1, 2, \ldots, N$ are continuously differentiable and $\sigma \in S_{\text{nonchat}}$, the existence of solutions of (2) can be guaranteed under some specific conditions [25]. However, the verification of the existence and uniqueness of solutions is not the concern of this paper for this reason, we skip the discussion on existence of solutions. For more details on the existence and uniqueness of solutions of autonomous differential equations, see [28] and references therein, since once the existence and uniqueness of each subsystem of (2) are guaranteed, the existence and uniqueness of solutions of (2) are guaranteed by verifying the existence and uniqueness exponential barrier function between each consecutive switching instants of the switching signal.

III. MAIN RESULT

The idea of the paper [1] about the safety and reachability verification by means of a barrier density is extended to the nonlinear switched systems under arbitrary switching signals and Proposition 1 is reformulated. Moreover, in the sequel, we have also mentioned that under which conditions weak safe reachibility results can be used to certify safe reachability of nonlinear switched system. Now, let us define safe reachability and weak safe reachability.

**Definition 1:** (Weak safe reachability) We say that the system (2) is (weakly) safely reachable on a domain $X$ from an initial set $X_0$ to a desired set $X_r$, avoiding an unsafe set $X_u$ if, for each switching signal $\sigma \in S_{\text{nonchat}}$, there exists a $T(x) > 0$ for (almost) every initial state $x \in X_0$ such that

\[
\phi_{T(x)}^\sigma(x) \in X_r,
\]

\[
\phi_t^\sigma(x) \notin X_u, \quad \text{for all } t \in [0, T(x)],
\]

\[
\phi_t^\sigma(x) \in X \quad \text{for all } t \in [0, T(x)],
\]

where $\phi_t^\sigma(x)$ denotes the solution of (2) for the switching signal $\sigma \in S_{\text{nonchat}}$ and for the initial state $x$.

(Weak) safe reachability from $X_0$ to $X_r$ avoiding $X_u$ is denoted as $X_0 \xrightarrow{\text{(a.c.)}} X_r$.

The following lemma is needed for the proof of Lemma 2, which is used to certify the change of volume with the change of density along the solutions of a system.

**Lemma 1:** [14] Assume that a set $D \subseteq \mathbb{R}^n$ is open, $\phi_t(x)$ is a solution of the system $\dot{x} = f(x)$ with an initial state $x$, $f(x), \rho(x)$ are continuously differentiable in $D$, and for a measurable set $A$, define $\phi_A(A) = \{ \phi_\sigma(x) | x \in A \}$. Assume that $\phi_A(A) \subseteq D$, for all $s \in [0, t]$. Then,

\[
\int_A \rho(x)dx - \int_A \rho(x)dx = \int_0^t \int_{\phi_\sigma(A)} |\nabla \cdot (f_\sigma)(\tau)|d\tau.
\]

One can see that $\frac{\partial \rho}{\partial t} = -\nabla \cdot (f u)$ is the continuity equation which is widely used for explaining the conservation of mass and it gives the evolution of density [29], [30] along the
solution $\phi_t(x)$ of $\dot{x} = f(x)$ with initial state $x$ by considering $u(x,t) := \rho((\phi_t(x)))^{-1} \left| \frac{\partial \rho((\phi_t(x)))^{-1}}{\partial x} \right|$. From (4), one can conclude that if $\frac{\partial \rho}{\partial t} = -\nabla \cdot (f \rho) = 0$, then the vector field is volume preserving. Moreover, if $\nabla \cdot (f \rho) > 0$, we can say that the volume along the flow of the vector field increases [31].

**Lemma 2:** [32] Assume that a set $D \subseteq \mathbb{R}^n$ is open, $\phi_t(x)$ is a solution of the system $\dot{x} = f(x)$ with an initial state $x$, and $f(x)$, $\rho(x)$ are continuously differentiable in $D$, and for a measurable set $A$, define $\phi_t(A) = \{ \phi_t(x) | x \in A \}$. Let $\rho$ is integrable in $D$ and $\nabla \cdot (f \rho) > 0$. Assume that $\phi_s(A) \subseteq D$, for all $s \in [0,t]$. Then, for a fixed $t > 0$, $\mu_\rho(\phi_t(A)) > \mu_\rho(A)$.

Next, we will give a way for verification of safe reachability properties of nonlinear switched systems with the aid of a Barrier density which is common for each subsystem (a common barrier density).

**Theorem 1:** Let $X \subseteq \mathbb{R}^n$ be bounded and $X_0$ be a set with positive Lebesgue measure. Assume that for the system (2), the sets $X_0 \subseteq X$, $X_u \subseteq X$ and $X_r \subseteq X$, are given and there exists a differentiable function $\rho$ in $\mathbb{R}^n$ satisfying the following properties

\[
\rho(x) > 0, \quad \forall x \in X_0, \quad (5a)
\]

\[
\nabla \cdot (f \rho_p)(x) > 0, \quad p = 1,2, \ldots, N, \forall x \in X \setminus X_r, \quad (5b)
\]

\[
\rho(x) < 0, \quad \forall x \in X \cap U_u, \quad (5c)
\]

Then, the system (2) is weakly safely reachable, $X_0 \xrightarrow{\text{sa}} X_r$.

**Proof:** Take an arbitrary switching signal $\sigma \in \mathcal{S}_\text{nonchatt}$. Let $\phi^\sigma_T(x)$ denotes the solution of (2) for the switching signal $\sigma \in \mathcal{S}_\text{nonchatt}$. Let $\phi^\sigma_T(A) = \{ \phi^\sigma_T(x) | x \in A \}$ for $t \geq 0$ be the set of solutions starting from an arbitrary set $A \subseteq X_0$ with positive measure. Assume that for some $T(x) > 0$ $\phi_{T(x)}(A) \subseteq X_0$ and $\phi^\sigma_T(A) \subseteq X_r$ and $\phi^\sigma_T(A) \subseteq X$ for all $t \in [0,T(x)]$. Utilizing Lemma 2 together with successive switching instants and considering condition (5a), we obtain $\mu_\rho(\phi^\sigma_T(x)) > \mu_\rho(A) > 0$. Therefore, there exists no set $A \subseteq X_0$ with positive measure such that for some $T(x) > 0$, $\phi_{T(x)}(A) \subseteq X$ and $\phi^\sigma_T(A) \subseteq X$ for all $t \in [0,T(x)]$.

Let us show reachability to the set $X_r$. Define $Z = \bigcup_{x \in X_0} \{ x \in X_0 | \phi^\sigma_T(x) \subseteq X \setminus X_r, \forall t \geq 0 \}$ and $\phi^\sigma_T(Z) \subseteq X \setminus X_r$, for all $t > 0$. By considering Lemma 2 together with $Z \subseteq X_0$ from 0 to $t$, we get $\mu_\rho(\phi^\sigma_T(Z)) > \mu_\rho(Z)$, for a fixed $t > 0$. The measure of all trajectories starting from $Z$ and lying in $X \setminus X_r$, can be computed as

\[
\mu_\rho(\phi^\sigma_T(Z)) = \sum_{i=1}^{\infty} \mu_\rho(\phi^\sigma_i(T))(Z). \quad (6)
\]

Applying the condition (5b) together with Lemma 1 between each switching instants, we get $\mu_\rho(\phi^\sigma_i(T)) > \mu_\rho(\phi^\sigma_{i-1}(T))$, $i \in \mathbb{Z}_{>0}$. Applying this iteratively together with condition (5a), it is obtained that

\[
\mu_\rho(\phi^\sigma_T(Z)) > \mu_\rho(Z), \quad i \in \mathbb{Z}_{>0}.
\]

Combining the previous sum with (6), we get $\mu_\rho(\phi^\sigma_T(Z)) > \sum_{i=1}^{\infty} \mu_\rho(Z)$. If $\mu_\rho(Z) > 0$, we have $\mu_\rho(\phi^\sigma_T(Z)) = \infty$, which contradicts to the assumption of the integrability of $\rho$ on $X$. Thus, the set $Z$ is included in a set with measure zero. Any solution which stays inside of the region $X \setminus X_r$ for all $t \geq 0$ is included in a set with measure zero. For almost every initial state, the solution $\phi^\sigma_t(x)$ leaves the region $X \setminus X_r$, i.e., either it leaves the domain $X$ or it enters the region $X_r$. From above discussion on safety, the set of solutions whose initial states are included in a set with positive measure cannot leave $X$ since $\rho$ is negative in $X^c$, so it reaches the set $X_r$ in a finite time. To conclude, there exists a time $T(x) > 0$, for almost every initial state $x$ in the set $X_0$, solution satisfy that $\phi^\sigma_T(x) \in X_r$. $\phi^\sigma_t(x) \notin X_u$ and $\phi^\sigma_t(x) \in X$ for all $t \in [0,T(x)]$.

If there exists a continuously differentiable function $\rho(x)$ on $\mathbb{R}^n$ satisfying the conditions (5a)-(5c) of Theorem 1, then we will call it a common barrier density.

When the set of initial states and the set of undesired states satisfy a certain topological properties, weak safe reachability implies safe reachability as shown in the next corollary.

**Corollary 1:** Let $X \subseteq \mathbb{R}^n$ be bounded and $X_0$ be a set with positive Lebesgue measure. Assume that the sets $X_0$ and $X_u$ satisfy the following property $\text{Int}(X_0) = X_0$ and $\text{Int}(X_u) = X_u$. If there exists a differentiable function $\rho$ in $\mathbb{R}^n$ satisfying the conditions (5a)-(5c) for a system (2) with the given sets $X_0 \subseteq X$, $X_u \subseteq X$, and $X_r \subseteq X$, then system (2) is safely reachable, $X_0 \xrightarrow{\text{sa}} X_r$.

**Proof:** Recall that if a non-empty set $A$ satisfies $\text{Int}(A) = A$, then for an arbitrary element $a \in A$, the intersection of any neighbourhood of $a$ with $A$ contains a non-empty open set. The conditions of (5a)-(5c) of Theorem 1 are satisfied with the given sets. Thus, (2) is weakly safely reachable. Let us assume that the system is not safely reachable, namely, for an arbitrary switching signal $\sigma \in \mathcal{S}_\text{nonchatt}$, (2) has a solution $\phi^\sigma_T(x)$ starting with an initial state $x$ from the set $X_0$ that reaches a point $\bar{x} := \phi^\sigma_T(x) \in X_u$. Then, there exists a sufficiently small neighbourhood $U_\delta$ of $\bar{x}$ and a non-empty open set $W$ such that $W \subseteq U_\delta \cap X_r$. Therefore, $\text{Int}(X_0) = X_0$ and continuity of the flow map $\phi^\sigma_T(x)$, we can say that there exists a non-empty open set $V$ such that $V \subseteq (\phi^\sigma_T(x) \setminus X_u)$ and $\mu_\rho(V) > 0$, which contradicts to the weak safety. Thus, for the given sets $X_0$ and $X_u$ the system is safe. Due to the fact that system is weak reachable, for almost every initial state $x$ in $X_0$ the solution of (2) reaches the set $X_r$ in a finite time. We can conclude that all solutions starting from the set $X_0$ reach the set $X_r$ due to continuous dependence of solutions with the initial state. Thus, system is safely reachable.

**Remark 2:** If there is a stable fixed point of the system in $X$, it should be removed from the domain. Otherwise, $\nabla \cdot (f \rho_p) > 0$ on $X$ implies that $\rho$ is not integrable on $X$.

**Remark 3:** If the condition (5b) is given as $\nabla \cdot (f \rho_p) \geq 0$, for all $p = 1,2, \ldots, N$, the safety property will be still valid since the solutions starting from $X_0$ will not reach the set $X_u$ since positivity of $\rho$ along the solutions starting in $X_0$ is still preserved. However, in this case, we cannot guarantee the reachability since under this condition the measure of the set
either increases or stays constant. To ensure reachability, one should show that the measure of a set is strictly increasing along the solutions.

IV. APPLICATION OF THE SUM OF SQUARES PROGRAMMING TO THE VERIFICATION OF SAFE REACHIBILITY

In this section, we will illustrate the theoretical results obtained in the previous section with the aid of an example, and we will give a brief summary of SoS programming with Putinar positivstellensatz. The Putinar positivstellensatz can be interpreted as follows: On a compact semi algebraically defined set \( K = \{x \in \mathbb{R}^n | p_1(x) \geq 0, p_2(x) \geq 0, \ldots, p_n(x) \geq 0\} \) to certify the non-negativity of a polynomial \( q \) is same as finding a sum of representation of \( q \) in the form \( q = s_0 + s_1p_1 + s_2p_2 + \ldots + s_n p_n \) for some sum of square polynomials \( s_0, s_1, \ldots, s_n \). Then, we can guarantee that the polynomial \( q \) is non-negative on the given sets. For this reason, in the example, we will use SoS together with Putinar Positivstellensatz [27] to search for a common Barrier density satisfying some non-negativity and non-positivity properties on the given sets since the given sets are semi algebraically defined and the vector fields are polynomials. The main advantage of using SoS with Putinar positivstellensatz is that it provides an algebraic formulation that is linear in unknown SOS polynomials. In other words, to certify if a polynomial is nonnegative boils down to finding a solution of a certain semi-definite programming problem.

In the example, the search of a Barrier density is done by means of SOSTOOLS, a sum of squares programming solver and SDPT3, a semi-definite programming solver.

In the following, we use a periodic switching signal as \( \{ (\Delta t_1, p_1), \ldots, (\Delta t_r, p_n) \} \), that is \( \{ (\Delta t_1, p_1), \ldots, (\Delta t_r, p_n), (\Delta t_1, p_1), \ldots \} \). Thus, the system has a switching signal with a period \( \Delta t_1 + \ldots + \Delta t_N \).

Example 1: (Example for a common Barrier density) Let us consider a nonlinear switched system (2) with the following subsystems:

\[
\begin{align*}
f_1(x) &= \begin{bmatrix} x_2 \\ -x_1 - x_2 + \frac{x_3^2}{27} \end{bmatrix}, \\
f_2(x) &= \begin{bmatrix} x_2 \\ -3x_1 - 2 - x_2 + \frac{x_3^2}{9} \end{bmatrix}.
\end{align*}
\]

A set of initial state, a set of undesired states (unsafe set), a set of desired states (reachable set) and a domain can be defined as

\[
\begin{align*}
X_0 &= \{x \in \mathbb{R}^2 | p_1(x) := -(x_1 - 1.5)^2 - x_2^2 + 0.5^2 \geq 0\}, \\
X_r &= \{x \in \mathbb{R}^2 | p_2(x) := -(x_1 - 1.5)^2 - x_2^2 + 0.5^2 \geq 0\}, \\
X_c &= \{x \in \mathbb{R}^2 | p_3(x) := -x_1^2 - x_2^2 + 0.5^2 \geq 0\},
\end{align*}
\]

respectively. To ensure that almost every solution starting from \( X_0 \) doesn’t leave \( X \) without entering \( X_r \), the following set

\[
X_d = \{x \in \mathbb{R}^2 | p_4(x) := -x_1^2 - x_2^2 + 3.5^2 \geq 0\},
\]

is needed. In the sequel, it will be discuss in details. Moreover, the set \( X_d \setminus X \) can be implemented to the conditions of Theorem 1 as a set of undesired states; i.e., by replacing the set \( X^c \) in condition (5b) with \( X_d \setminus X \).

Considering the above given sets, the conditions (5a)-(5c) of Theorem 1 can be converted to the following form:

- \( \rho(x) > 0 \), for all \( x \in X_0 \),
- \( \nabla \cdot (\rho(x)f_i(x)) > 0 \), \( i = 1, 2 \), for all \( x \in X \setminus X_r \), and
- \( \rho(x) \leq 0 \) for all \( x \in (X_d \setminus X) \cup X_r \).

The problem of finding such a function \( \rho \) as a polynomial can be interpreted as looking for an SoS representation by using Putinar positivstellensatz on the semi algebraically defined given sets with the polynomial vector fields.

By searching \( \rho \), as a polynomial and using SoS algorithm together with Putinar Positivstellensatz, we will verify the safely reachability of the system by using common Barrier density. The conditions (5a)-(5c) of Theorem 1 can be converted to SoS algorithm with the Putinar positivstellensatz as:

- \( \text{sos}(\rho - s_1p_1 - \epsilon) \),
- \( \text{sos}(-\rho - s_2p_2) \),
- \( \text{sos}(-\rho - s_3p_5 + p_4s_4) \),
- \( \text{sos}(\nabla \cdot (f_1)\rho + \nabla \rho \cdot f_1 - \epsilon - s_5p_4 + s_6p_3) \) and
- \( \text{sos}(\nabla \cdot (f_2)\rho + \nabla \rho \cdot f_2 - \epsilon - s_7p_4 + s_8p_3) \),

where \( s_i, i = 1, 2, \ldots, 8 \) are sum of square polynomials and \( \epsilon \) is a sufficiently small positive number. We have obtained a tenth degree polynomial \( \rho \) by applying the above SOS algorithm with a tolerance \( \epsilon = 0.005 \). We use such tolerance to guarantee that the density is positive on \( X_0 \) and \( \nabla \cdot (f \rho) > 0 \) on \( X \setminus X_r \). Thus, the existence of barrier density proves that the system is weak safely reachable from \( X_0 \) to \( X_r \), avoiding \( X_u \). Additionally, given sets \( X_0 \) and \( X_r \) satisfy the condition \( \text{Int}(X_0) = X_0 \) and \( \text{Int}(X_r) = X_r \) of Corollary 1, then we can say that the system is safely reachable from \( X_0 \) to \( X_r \), avoiding \( X_u \).

Figure 1 is obtained by using the given subsystems with a switching signal \( \{ (0.4, 1), (0.3, 2) \} \). The dashed curve in Figure 1 is drawn to indicate the places where \( \rho = 0 \). In the inside of the dashed curve where the measure of the set of solutions starting from \( X_0 \) is positive and at the outside of the curve where the undesired states present, the density \( \rho \) takes negative values. The undesired set is taken as close as possible to the barrier \( \rho(x) = 0 \) by checking feasibility of the SoS algorithm given above.

V. CONCLUSION

We have extended the idea of verification of safe reachability to switched nonlinear systems with time dependent switching via a common barrier density. We have shown that the safely reachability analysis can be carried out by means of SoS programming together with Putinar positivstellensatz.

As a further work, the proposed method for the verification of the safe reachability of nonlinear switched systems can
be extended for switched systems with state dependent switching. Furthermore, common barrier density approach can be used for model invalidation and for detection of the faults in a nonlinear switched system.
