Abstract. Biochars were prepared via the pyrolysis of sewage sludge at temperatures ranging from 350–550 °C. The properties and behaviors of heavy metals in the biochars were investigated. The results indicated that the pH values and ash contents of the biochars increased, while biochar yield and C, H, and N contents decreased with the increasing temperature. A high pyrolysis temperature contributed to a developed biochar pore structure. The specific surface area and pore volume of the biochars increased, while the average pore width decreased, with the increasing temperature. Heavy metals in the biochars were further enriched with the increasing temperature. TCLP tests demonstrated that the leaching potential of heavy metals from the biochars significantly decreased with the increasing temperature, indicating the decrease of potential ecological risks of heavy metals to the environment. Additionally, BCR tests confirmed the transformation of heavy metals from mobile fractions (F1 and F2) to stable fractions (F3 and F4). The evaluation results showed that a high pyrolysis temperature can effectively inhibit the ecological risks of heavy metals in the biochars. Thus, the conversion of sewage sludge into biochar via pyrolysis is a promising method for the safe disposal of sewage sludge.

1 Introduction

Sewage sludge is a by-product of municipal wastewater treatment plants. With continuous urbanization worldwide, many municipal sewage treatment plants have been constructed, and the amount of discharged sewage sludge is increasing dramatically. Sewage sludge contains a large amount of heavy metals and pathogenic microbes that can cause serious environmental pollution and even threaten human health once directly discharged into the environment [1]. The proper disposal of sewage sludge has attracted great interest, and the organic composition in sewage sludge is also considered as an important biological resource. Therefore, it is necessary to develop appropriate disposal technology to both reuse resources and safely dispose of sewage sludge.

Pyrolysis may provide a feasible and attractive strategy for sludge recycling [2], since it can reduce sludge volume, kill pathogens and parasites [3], and convert the organic matter in sewage sludge into bio-oil, pyrolysis gas, and biochar [4]. Sludge-derived biochar is a kind of porous material with an abundance of nutrients including N, P, and K [5]. It is also a potential amendment to contaminated soil, and its application to soils may decrease soil bulk density [6], increase soil porosity [7], enhance soil water holding capacity [8-10], increase soil nutrient retention capacity [10], adsorb soil pollutants [11], improve the nutrient supply for plants [12], and enhance plant growth [13].

The characteristics of sludge-derived biochars have an important influence on their improvement to degraded soils. Detailed research is required on the elemental compositions, physicochemical properties, and pore structures of sludge-derived biochars. Moreover, sludge-derived biochars are enriched in heavy metals [14], and the behaviors of those heavy metals require further research to minimize the risks of their release into the environment. Pyrolysis temperature is the key factor that determines the characteristics of biochar [15-16]. Therefore, the aims of this study are (1) to investigate the effect of pyrolysis temperature on the properties of sludge-derived biochar, (2) to explore the effects of pyrolysis temperature on the transformations of heavy metals during the pyrolysis process, and (3) to reduce the potential ecological risks of heavy metals in biochar.

2 Materials and methods
2.1 Pyrolysis feedstocks

The sewage sludge used in this study was collected from the sludge dehydrating unit of a municipal wastewater treatment plant in Urumqi, Xinjiang Province, China, and was air dried outdoors. The sludge was dried to constant weight at 85 °C in a laboratory oven, ground through a 60-mesh sieve, and packed in sealed plastic bags for further use. The sludge is labeled as SS. The properties of the sludge are listed in Table 1.

2.2 Pyrolysis experiments

The pyrolysis experiments were conducted at a pyrolysis temperature ranging from 350 to 550 °C [17] and a heating rate of 20 °C/min in an electric heating furnace. Figure 1 presents a schematic diagram of the furnace consisting of a nitrogen conveyor, a pyrolysis reactor, and a liquid separator.

Before and during the pyrolysis process, a continuous inflow of N\(_2\) at 0.5 L/min was sent to the furnace to achieve an oxygen-free environment. A total of 30 g of dry SS was placed in the quartz tube, fed into the middle portion of the furnace, and heated for 2 h after reaching the target temperature. The solid products (biochars) were cooled to room temperature and weighed, and the biochar yield was determined according to equation (1).

\[ Y_b = \frac{M_b}{M_s} \]  

where \(Y_b\) represents the yield of the biochar, and \(M_b\) and \(M_s\) represent the dry weights of the biochar and sludge, respectively.

2.3 Characterization of the sludge and biochars

The C, H, and N contents of the sludge and biochars were determined simultaneously by using an elemental analyzer (Flash, Ea11121, USA). The pH values of the samples (sample/water, 1:20, w/v) were measured with a digital pH meter (PHS-3C, China). The BET (Brunauer–Emmett–Teller) surface area, pore volume, and pore size of the samples were determined with an automated surface area and pore size analyzer (ASAP2020; Micrometrics, USA). The ash contents of the samples were measured according to the methods listed in the standard procedures of the Chinese standard GB/T212-2008 [18].

2.4 Analytical methods for heavy metals

Before the total contents of heavy metals in the sludge and biochars were tested, these samples were first digested according to Wang et al [19]. The BCR (the European Community Bureau of Reference) sequential extraction method was used to analyze the chemical form distributions of heavy metals in the samples [20]. The TCLP (toxicity characteristic leaching procedure) was used to analyze the leachable toxicities of heavy metals in the samples [21]. The concentrations of heavy metals in the solutions were determined by using inductively coupled plasma optical emission spectrometry (ICP-OES, Optima5300, Perkin Elmer, USA). The ecological risks of heavy metals in the sludge and biochars were assessed according to Wang et al [19].

2.5 Statistical analyses

Statistical analyses were performed by using the SPSS statistical package (v. 19.0, IBM Corp., Armonk, NY, USA). The data were subjected to variance analysis. The means were separated by using the protected least significant difference test at \(p < 0.05\).

3 Results and Discussions

3.1 General Properties

The general properties of the samples (the sludge and biochars) are listed in Table 1. The biochar yield decreased from 73.33% to 61.28% with the increase of pyrolysis temperature from 350 to 550 °C. Moreover, compared with the sludge, the contents of C, H, and N of biochar SSB350 obviously decreased after pyrolysis at 350 °C. The decomposition of organic matter into volatile substances during the pyrolysis process was the

---

**Table 1. General properties of the sludge and biochars.**

| Samples  | Yield (%) | pH (±) | C (%) | H (%) | N (%) | H/C | Ash (%) |
|----------|-----------|--------|-------|-------|-------|-----|---------|
| SS       | -         | 7.03 ± 0.05 | 26.15 | 3.86  | 4.57  | 0.15 | 46.66 ± 2.15 |
| SSB350   | 73.33 ± 1.20 | 7.42 ± 0.03 | 25.32 | 2.16  | 3.15  | 0.09 | 55.14 ± 2.39  |
| SSB450   | 67.13 ± 1.13 | 8.07 ± 0.02 | 24.28 | 1.71  | 2.98  | 0.07 | 64.36 ± 3.11   |
| SSB550   | 61.28 ± 0.92 | 8.54 ± 0.03 | 19.89 | 1.09  | 2.35  | 0.05 | 72.42 ± 2.84   |

*a*Not determined.

*b*On a dried base.
reason for these decreases [22]. Furthermore, the contents of these elements gradually decreased with the increase of pyrolysis temperature, indicating the increased thermal decomposition of organic matter at higher temperatures. These results were consistent with the research of Jin et al [23]. The H/C atomic ratio of the biochars obviously decreased with the increase of temperature, indicating that an elevated temperature can increase the aromatization degree of biochar [20], [24-25].

The ash content of biochar was positively correlated with pyrolysis temperature. When the pyrolysis temperature increased from 350 to 550 °C, the ash content of the biochar increased from 55.14% to 72.42%. In this study, higher pyrolysis temperatures resulted in higher alkalinity of the biochar. There were two main mechanisms to explain this phenomenon. First, more alkali salts were released from the organic structure at higher temperatures. Second, more organic amines were converted to pyridines with the increase of pyrolysis temperature, resulting in the decrease of acid functional groups on the biochar surface.

3.2 Characterization of the biochars

The pore structure characteristics of the sludge and biochars are exhibited in Table 2. The results suggest that pyrolysis of the sludge at higher temperatures promoted the development of the pore structures of biochars. When the temperature increased from 350 to 550 °C, the specific surface area and total pore volume of the biochars increased from 8.01 m²/g and 0.041 cm³/g to 10.23 m²/g and 0.062 cm³/g, respectively, while the average pore size decreased from 23.50 nm to 16.40 nm. The volatilization of organic matter in biochar is helpful to the development of pore structure [20].

| Pore structure       | SS  | SSB350 | SSB450 | SSB550 |
|----------------------|-----|--------|--------|--------|
| Surface area (m²/g)  | 4.35| 8.01   | 8.78   | 10.23  |
| Total pore volume (cm³/g) | 0.013 | 0.041 | 0.049 | 0.062 |
| Average pore width (nm) | 55.41 | 23.50 | 22.10 | 16.40 |

Table 2. Pore structures of the sludge and biochars.

In this study, the biochars prepared at different temperatures were mesoporous materials. As shown in Figure 2, the N₂ adsorption isotherms of these biochars corresponded to similar type IV adsorption isotherms according to IUPAC (International Union of Pure and Applied Chemistry) classification. As shown in Figure 3, the pore size distributions of the biochars were similar, and had similar peak horizontal positions.

**Fig. 2.** Nitrogen adsorption-desorption isotherms of biochars obtained at different pyrolysis temperatures.

**Fig. 3.** The pore size distribution of biochar obtained at different pyrolysis temperatures.

3.3 Metal analysis

3.3.1 Total concentrations of heavy metals

The total concentrations of metals in the sludge and biochars are presented in Figure 4. Of the six heavy metals, the total concentration of Zn in the sludge was the highest and reached 587.04 mg/kg, which may be due to the widespread use of galvanized drainage pipes in municipal drainage networks.

The total concentrations of the six heavy metals in biochar SSB350 increased significantly after pyrolysis at 350 °C, and, except for Cd, the higher the pyrolysis temperature was, the greater the total concentration of heavy metal was. This result indicates that higher...
pyrolysis temperatures caused the enrichment of heavy metals in the biochars.

**Fig. 4.** Total concentrations of heavy metals in the sludge and biochars.

### 3.3.2 Concentrations of BCR-extractable fractions

The BCR (European Community Bureau of Reference) method is always used to quantitatively analyze the chemical form distributions of heavy metals in sediment, soil, and biochars [4,26]. According to the BCR method, heavy metals are classified into four chemical forms: (1) acid soluble/exchangeable fraction (F1), (2) reducible fraction (F2), (3) oxidizable fraction (F3), and (4) residual fraction (F4), including residual and silicate-bound heavy metals [27]. The chemical form distributions of the six heavy metals in the sludge and biochars are presented in Figure 5.

**Fig. 5.** Chemical form distributions of heavy metals in the sludge and biochars.

For Pb, the percentages of F1, F2, F3, and F4 in the sludge were 1.36%, 27.90%, 7.92%, and 62.82%, respectively. Compared with the sludge, the percentages of Pb in F1 and F2 in biochar SSB350 decreased, while those in F3 and F4 obviously increased. Furthermore, when the temperature increased from 350 °C to 550 °C, the percentage of Pb in F1 decreased from 0.90% to 0%, and that in F2 decreased from 27.90% to 21.88%. In contrast, the percentages of Pb in F3 and F4 increased from 7.92% to 9.31% and 62.82% to 67.91%, respectively.
respectively. These results suggest that pyrolysis at a high temperature effectively promoted the transformation of Pb from F1 and F2 to F3 and F4. Meanwhile, the increase of temperature had similar effects on the chemical form distributions of the other five heavy metals (Cd, Cu, Cr, Zn, and Ni).

During the pyrolysis process, organic compounds in the sludge were decomposed into phenols, acids, and aromatic compounds, and heavy metals combined with organic functional groups, such as hydroxyl groups, to form stable coordination compounds [28]. Moreover, some metals combined with Si-O bonds [26]. These factors caused the transformations of those heavy metals from F1 and F2 to F3 to F4. Previous research has confirmed that metals presenting in F3 and F4 are more stable in the environment than those in F1 and F2 [29]. Therefore, pyrolysis can effectively stabilize heavy metals in sludge and reduce the possibility of their release into the environment.

### Table 3. Leaching toxicities of the heavy metals from the sludge and biochars.

| Samples   | Heavy metals (mg/g) |
|-----------|---------------------|
|           | Pb                  | Cr | Cd | Cu | Zn | Ni |
| SS        | 0.53(2.55)a         | 3.21(3.20) | 0.16(9.34) | 30.80(9.22) | 34.99(5.96) | 1.34(3.53) |
| SSB350    | 0.31(1.21)          | 1.73(1.52) | 0.14(4.78) | 20.13(5.56) | 22.83(2.34) | 0.51(1.75) |
| SSB450    | 0.29(1.07)          | 1.50(1.22) | 0.13(4.44) | 12.11(3.24) | 22.19(2.18) | 0.46(1.28) |
| SSB550    | 0.25(0.83)          | 1.05(0.78) | 0.10(3.27) | 10.65(2.63) | 15.07(1.39) | 0.43(1.03) |
| Standard  | 5.0                 | 5.0 | 1.0 | Not enlisted | Not enlisted | 5.0 |

3.3.3 Leachable toxicity of heavy metals

The leaching characteristics of the heavy metals in the sludge and biochars are exhibited in Table 3. In this study, the leaching contents of all six heavy metals from the sludge and biochars were below the permissible limits [18]. Compared with the sludge, the leaching contents of the six heavy metals in biochar SSB350 decreased significantly, and the increase in temperature further reduced the leaching contents of these heavy metals. For Pb, the leaching content decreased from 0.31 mg/g to 0.25 mg/g, and the leaching rate decreased from 1.21% to 0.83%. The leaching characteristics of the other five heavy metals exhibited similar trends. Thus, pyrolysis at a high temperature had a noticeable effect on the alleviation of the leaching toxicities of the six heavy metals in the sludge. This observation was in accordance with that obtained by Jin et al [23].

3.3.4 Ecological risk assessment of heavy metals

The ecological risk index (GRI) is always used to evaluate the ecological risks of single and multiple metals in water, sediment, soil, and biochars [18], [20]. In this study, this method was used to assess the ecological risks of heavy metals in the sludge and biochars prepared at different pyrolysis temperatures, and the values were computed by using the following formulas:

\[
ICF = \frac{C_{F1+F2+F3}}{C_{F4}}
\]

(2)

\[
GCF = \sum_{i=1}^{n} ICF_i
\]

(3)

\[
GRI = \sum_{i=1}^{n} Tr_i ICF_i
\]

(4)

where \(C_{F1+F2+F3}\) is the sum of the total concentrations of a single heavy metal presenting in fractions F1 + F2 + F3, \(C_{F4}\) is the total concentration of a single heavy metal in fraction F4, and \(Tr_i\) is the toxic response factor, which is the response factor for the ecological toxicity of a single heavy metal [30]. Furthermore, ICF and GCF are the contamination factors of a single heavy metal and multi-metals, respectively. GRI represents the ecological risks of heavy metals (Pb, Zn, Cd, Cr, Cu, and Ni) in the samples. The ICF, GCF, and GRI values of the samples are listed in Table 4.

### Table 4. Assessment of ecological risks of heavy metals in the sludge and biochars.

| Samples   | Pb   | Cr   | Cd   | Cu   | Zn   | Ni   | ICFa | GCFb | GRI  |
|-----------|------|------|------|------|------|------|------|------|------|
| SS        | 0.59 | 7.28 | 1.49 | 3.02 | 8.49 | 8.43 | 29.20| 137.43 |
| SSB350    | 0.47 | 6.84 | 2.36 | 2.30 | 6.47 | 5.45 | 23.89| 137.25 |
| SSB450    | 0.42 | 5.68 | 1.22 | 2.16 | 7.62 | 3.95 | 21.05| 94.20 |
| SSB550    | 0.39 | 3.94 | 0.95 | 1.69 | 5.66 | 2.49 | 15.12| 69.13 |

*ICF*: ≤1, 1–3, 3–6, and >6 denote low, moderate, considerable, and high contamination risks, respectively.
The assessment results reveal that the ICF value of Zn was the highest of the six heavy metals for both the sludge and the biochars. The GCF value of the sludge was 29.20. After pyrolysis at 350 °C, the GCF value of the biochar SCB350 decreased to 23.89. Moreover, the GCF values of the biochars obviously decreased with the increase of pyrolysis temperature (Table 4). In the GRI analysis, the GRI values of the sludge and SSB350 were 137.43 and 137.25, respectively, which are both at the low risk level. Additionally, the GRI values of the biochars decreased with the increase of pyrolysis temperature. These results suggest that the evaluated pyrolysis temperatures effectively reduced the ecological risks of both single and multiple heavy metals in the biochars.

This can be explained as follows. During the pyrolysis process, metals presenting in mobile fractions F1 and F2 were released from the organic structure of the sludge and transferred into stable fractions F3 and F4, resulting in the decrease of ecological risks of those heavy metals. Furthermore, the increase of pyrolysis temperature enhanced this process, as shown in Figure 5.

4 Conclusions

With the increase of pyrolysis temperature, the biochar yield decreased obviously, but the pH value and ash content increased. Additionally, the increase of pyrolysis temperature reduced the H/C ratio of the biochar, increased its specific surface area and total pore volume, and reduced its pore size. The total concentration of heavy metals in the biochars further increased with the increase of pyrolysis temperature. Elevated pyrolysis temperatures effectively inhibited the leaching potential of heavy metals from the biochars, contributed to the transformation of heavy metals from mobile fractions (F1 and F2) to stable ones (F3 and F4), and effectively reduced the potential ecological risks of heavy metals in the biochars. These results suggest that biochar prepared via the pyrolysis of sewage sludge at a high temperature is more suitable for soil improvement. However, the effects of pyrolysis residence time and heating rate on the characteristics of sewage sludge-derived biochar require further investigation.
