On Takens’ last problem: tangencies and
time averages near heteroclinic networks

Abstract
We obtain a structurally stable family of smooth ordinary differential equations exhibiting heteroclinic tangencies for a dense subset of parameters. We use this to find vector fields $C^2$-close to an element of the family exhibiting a tangency, for which the set of solutions with historic behaviour contains an open set. This provides an affirmative answer to Takens’ last problem (Takens 2008 Nonlinearity 21 T33–6). A limited solution with historic behaviour is one for which the time averages do not converge as time goes to infinity. Takens’ problem asks for dynamical systems where historic behaviour occurs persistently for initial conditions in a set with positive Lebesgue measure.

The family appears in the unfolding of a degenerate differential equation whose flow has an asymptotically stable heteroclinic cycle involving two-dimensional connections of non-trivial periodic solutions. We show that the degenerate problem also has historic behaviour, since for an open set of initial conditions starting near the cycle, the time averages approach the boundary of a polygon whose vertices depend on the centres of gravity of the periodic solutions and their Floquet multipliers.

We illustrate our results with an explicit example where historic behaviour arises $C^2$-close of a $SO(2)$-equivariant vector field.

1. Introduction

Chaotic dynamics makes it difficult to give a geometric description of an attractor in many situations, when probabilistic and ergodic analysis becomes relevant. In a long record of a chaotic signal generated by a deterministic time evolution, for suitable initial conditions the expected time average exists—see [29, 30]. However, there are cases where the time averages do not converge no matter how long we wait. This historic behaviour is associated with intermittent dynamics, which happens typically near heteroclinic networks.

The aim of this article is to explore the persistence of this behaviour for a deterministic class of systems involving robust heteroclinic cycles, leading to an answer to Takens’ Last Problem [34]. More precisely, we study non-hyperbolic heteroclinic attractors such that the time averages of all solutions within their basin of attraction do not converge, and for which this holds persistently.

This is done by first studying a one-parameter family of vector fields having periodic solutions connected in a robust cycle. We show that under generic conditions there are parameter values for which the invariant manifolds of a pair of periodic solutions have a heteroclinic tangency. This implies the Newhouse property of existence of infinitely many sinks. Results by Kiriki and Soma [17] may then be used to provide an affirmative answer to the problem proposed by Takens in [34].

1.1. Takens’ last problem

Let $M$ be a compact three-dimensional manifold without boundary and consider a vector field $f: M \to TM$ defining a differential equation

$$\dot{x} = f(x), \quad x(0) = x_0 \in M$$

and denote by $\phi(t, x_0)$, with $t \in \mathbb{R}$, the associated flow with initial condition $x_0 \in M$. The following terminology has been introduced by Ruelle [29] (see also Sigmund [30]).

**Definition 1.** We say that the solution $\phi(t, x_0)$, $x_0 \in M$, of (1.1) has historic behaviour if there is a continuous function $H : M \to \mathbb{R}$ such that the time average

$$\frac{1}{T} \int_0^T H(\phi(t, x_0)) \, dt$$

fails to converge.

A solution $\phi(t, x_0), x_0 \in M$ with historic behaviour retains informations about its past. This happens, in particular, if there are at least two different sequences of times, say $(T_i)_{i \in \mathbb{N}}$ and $(S_j)_{j \in \mathbb{N}}$, such that the following limits exist and are different:

$$\lim_{i \to +\infty} \frac{1}{T_i} \int_0^{T_i} H(\phi(t, x_0)) \, dt \neq \lim_{j \to +\infty} \frac{1}{S_j} \int_0^{S_j} H(\phi(t, x_0)) \, dt.$$
The consideration of the limit behaviour of time averages with respect to a given measure has been studied since Sinai [31], Ruelle [28] and Bowen [4]. Usually, historic behaviour is seen as an anomaly. Whether there is a justification for this belief is the content of Takens’ last problem [17, 33, 34]: are there persistent classes of smooth dynamical systems such that the set of initial conditions which give rise to orbits with historic behaviour has positive Lebesgue measure? In ergodic terms, this problem is equivalent to finding a persistent class of systems admitting no physical measures [10, 29], since roughly speaking, these measures are those that give probabilistic information on the observable asymptotic behaviour of trajectories.

The class may become persistent if one considers differential equations in manifolds with boundary as in population dynamics [10, 12]. The same happens for equivariant or reversible differential equations [9]. The question remained open for systems without such properties until, recently, Kiriki and Soma [17] proved that any Newhouse open set in the $C^r$-topology, $r \geq 2$, of two-dimensional diffeomorphisms is contained in the closure of the set of diffeomorphisms which have non-trivial wandering domains whose forward orbits have historic behaviour. As far as we know, the original problem, stated for flows, has remained open until now.

1.2. Non-generic historic behaviour

In this section, we present some non-generic examples that, however, occur generically in families of discrete dynamical systems depending on a small number of parameters. The first example has been given in Hofbauer and Keller [11], where it has been shown that the logistic family contains elements for which almost all orbits have historic behaviour. This example has codimension one in the space of $C^3$ endomorphisms of the interval; the $C^3$ regularity is due to the use of the Schwarzian derivative operator.

The second example is due to Bowen, who described a codimension two system of differential equations on the plane whose flow has a heteroclinic cycle consisting of a pair of saddle-equilibria connected by two trajectories. As referred by Takens [33, 34], apparently Bowen never published this result. We give an explicit example in section 7.2 below. The eigenvalues of the derivative of the vector field at the two saddles are such that the cycle attracts solutions that start inside it. In this case, each solution in the domain has historic behaviour. In ergodic terms, it is an example without SRB measures. Breaking the cycle by a small perturbation, the equation loses this property. This type of dynamics may become persistent for dynamical systems in manifolds with boundary or in the presence of symmetry. We use Bowen’s example here as a first step in the construction of a generic example. Other examples of high codimension with heteroclinic attractors where Lebesgue almost all trajectories fail to converge have been given by Gaunersdorfer [8] and Sigmund [30].

Ergodicity implies the convergence of time averages along almost all trajectories for all continuous observables [16]. For non-ergodic systems, time averages may not exist for almost all trajectories. In Karabacak and Ashwin [16, theorem 4.2], the authors characterise conditions on the observables that imply convergent time averages for almost all trajectories. This convergence is determined by the behaviour of the observable on the statistical attractors (subsets where trajectories spend almost all time). Details in [16, section 4].

1.3. General examples

The paradigmatic example with persistent historic behaviour has been suggested by Colli and Vargas in [6], in which the authors presented a simple non-hyperbolic model with a wandering domain characterised by the existence of a two-dimensional diffeomorphism with a Smale horseshoe whose stable and unstable manifolds have persistent tangencies under arbitrarily small $C^2$ perturbations.
The authors of [6] suggest that this would entail the existence of non-wandering domains with historic behaviour, in a robust way. This example has been carefully described in [17, section 2.1].

For diffeomorphisms, an answer has been given by Kiriki and Soma [17], where the authors used ideas suggested in [6] to find a nontrivial non-wandering domain (the interior of a specific rectangle) where the diffeomorphism is contracting. In a robust way, they obtain an open set of initial conditions for which the time averages do not converge. Basically, the authors linked two subjects: homoclinic tangencies studied by Newhouse, Palis and Takens and non-empty non-wandering domains exhibiting historic behaviour. An overview of the proof has been given in section 2 of [17]. We refer those that are unfamiliar with Newhouse regions to the book [23].

1.4. The results

The goal of this article is twofold. First, we extend the results by Takens [33] and by Gaunersdorfer [8] to heteroclinic cycles involving periodic solutions with real Floquet multipliers. The first main result is theorem 8, with precise hypotheses given in section 3:

1st result: Consider an ordinary differential equation in \( \mathbb{R}^3 \) having an attracting heteroclinic cycle involving periodic solutions with two-dimensional heteroclinic connections. Any neighbourhood of this cycle contains an open set of initial conditions, for which the time averages of the corresponding solutions accumulate on the boundary of a polygon, and thus, fail to converge. The open set is contained in the basin of attraction of the cycle and the observable is the projection on a component.

This situation has high codimension because each heteroclinic connection raises the codimension by one, but this class of systems is persistent in equivariant differential equations. The presence of symmetry creates flow-invariant fixed-point subspaces in which heteroclinic connections lie—see for example the example constructed in [27, section 8]. Another example is constructed in section 7.4 below. The second main result, theorem 11, concerns tangencies:

2nd result: Consider a generic one-parameter family of structurally stable differential equations in the unfolding of an equation for which the 1st result holds. Then there is a sequence of parameter values for which there is a heteroclinic tangency of the invariant manifolds of two periodic solutions.

We use this result to obtain theorem 12:

3rd result: Consider a generic one-parameter family of structurally stable differential equations in the unfolding of an equation for which the 1st result holds. Therefore, for parameter values in an open interval, there are vector fields arbitrarily \( C^2 \)-close to an element of the family, for which there is an open set of initial conditions exhibiting historic behaviour.

In other words, we obtain a class, dense in a \( C^2 \)-open set of differential equations, and elements of this class exhibit historic behaviour for an open set of initial conditions, which may be interpreted as the condition required in Takens’ last problem. The idea behind the proof goes back to the works of [14, 15], combined with the recent progress on the field made by [17]. The proof consists of the following steps:

1. use the 3rd result to establish the existence of intervals in the parameters corresponding to Newhouse domains;
2. in a given cross section, construct a diffeomorphism (\( C^2 \)-close to the first return map) having historic behaviour for an open set of initial conditions;
3. transfer the historic behaviour from the perturbed diffeomorphism of 2. to a flow \( C^2 \)-close to the original one.

Furthermore, in the spirit of the example by Bowen described in [33], we obtain:

**4th result:** We construct explicitly a class of systems for which historic behaviour arises \( C^2 \)-close to the unfolding of a fully symmetric vector field, having an open set of initial conditions with historic behaviour. In contrast to the findings of Bowen and Kleptsyn [18], our example is robust due the hyperbolicity of the periodic solutions and the transversality of the local heteroclinic connections.

The results in this article are stated for vector fields in \( \mathbb{R}^3 \), but they hold for vector fields in a three-dimensional Riemannian manifold and, with some adaptation, in higher dimensions.

### 1.5. An ergodic point of view

Concerning the first result, the outstanding fact in the degenerate case is that the time averages diverge precisely in the same way: they approach a \( k \)-polygon. This is in contrast with ergodic and hyperbolic strange attractors admitting a physical measure, where almost all initial conditions lead to converging time averages, in spite of the fact that the observed dynamics may undergo huge variations.

If a flow \( \phi(t,\cdot) \) admits an invariant probability measure \( \mu \) that is absolutely continuous with respect to the Lebesgue measure and ergodic, then \( \mu \) is a physical measure for \( \phi(t,\cdot) \), as a simple consequence of the Birkhoff Ergodic theorem. In other words if \( H : M \to \mathbb{R} \) is a \( \mu \)-integrable function, then for \( \mu \)-almost all points in \( M \) the time average:

\[
\lim_{T \to +\infty} \frac{1}{T} \int_0^T H \circ \phi(t,x_0)dt
\]

exists and equals the space average \( \int H d\mu \). In the conservative context, historic behaviour has zero Lebesgue measure.

Physical measures need not be unique or even exist in general. When they exist, it is desirable that the set of points whose asymptotic time averages are described by physical measures be of full Lebesgue measure. It is unknown in how much generality do the basins of physical measures cover a subset of \( M \) of full Lebesgue measure. There are examples of systems admitting no physical measure but the only known cases are not robust, i.e. there are systems arbitrarily close (in the Whitney \( C^2 \) topology) that admit physical measures. In the present article, we exhibit a persistent class of smooth dynamical systems that does not have global physical measures. In the unfolding of an equation for which the first result holds, there are no physical measures whose basins intersect the basin of attraction of an attracting heteroclinic cycle. Our example confirms that physical measures need not exist for all vector fields. Existence results are usually difficult and are known only for certain classes of systems.

### 1.6. Example without historic behaviour

Generalised Lotka–Volterra systems has been analysed by Duarte et al in [7]. Results about the convergence of time averages are known in two cases: either if there exists a unique interior equilibrium point, or in the conservative setting (see [7]), when there is a heteroclinic cycle. In the latter case, if the solution remains limited and does not converge to the cycle, then its time averages converge to an equilibrium point. The requirement is that the heteroclinic cycle is stable but not attracting. The limit dynamics has been extended to polymatrix replicators in
This is in contrast to our findings in the degenerate case, emphasising the importance of the hypothesis that the cycle is attracting in order to obtain convergence to a polygon.

1.7 Framework of the article

Preliminary definitions are the subject of section 2 and the main hypotheses are stated in section 3. We introduce the notation for the rest of the article in section 4 after a linearisation of the vector field around each periodic solution, whose details are given in appendix A. We use precise control of the times of flight between cross-sections in section 5, to show that for an open set of initial conditions in a neighbourhood of asymptotically stable heteroclinic cycles involving non-trivial periodic solutions, the time averages fail to converge. Instead, the time averages accumulate on the boundary of a polygon, whose vertices may be computed from local information on the periodic solutions in the cycle. The proofs of some technical lemmas containing the computations about the control of the flight time between nodes appear in appendix B, to make for easier reading.

In section 6, we obtain a persistent class of smooth dynamical systems such that an open set of initial conditions corresponds to trajectories with historic behaviour. Symmetry-breaking techniques are used to obtain a heteroclinic cycle associated to two periodic solutions and we find heteroclinic tangencies and Newhouse phenomena near which the result of [6, 17] may be applied. This is followed in section 7 by an explicit example where historic behaviour arises in the unfolding of an $\text{SO}(2)$-equivariant vector field.

2. Preliminaries

To make the paper self-contained and readable, we recall some definitions.

2.1 Heteroclinic attractors

Several definitions of heteroclinic cycles and networks have been given in the literature. In this paper we consider non-trivial periodic solutions of (1.1) that are hyperbolic and that have one Floquet multiplier with absolute value greater than 1 and one Floquet multiplier with absolute value less than 1. A connected component of $W^s(P) \setminus P$, for a periodic solution $P$, will be called a branch of $W^s(P)$, with a similar definition for a branch of $W^u(P)$. Given two periodic solutions $P_a$ and $P_b$ of (1.1), a heteroclinic connection from $P_a$ to $P_b$, is a trajectory contained in $W^s(P_a) \cap W^u(P_b)$, that will be denoted $[P_a \to P_b]$.

Let $S = \{P_a : a \in \{1, ..., k\}\}$ be a finite ordered set of periodic solutions of saddle type of (1.1). The notation for $P_a$ is cyclic, we indicate this by taking the index $a \mod k$, i.e. $a \in \mathbb{Z}_k = \mathbb{Z}/k\mathbb{Z}$. Suppose

$$\forall a \in \mathbb{Z}_k \quad W^s(P_a) \cap W^u(P_{a+1}) = \emptyset.$$ 

A heteroclinic cycle $\Gamma$ associated to $S$ is the union of the saddles in $S$ with a heteroclinic connection $[P_a \to P_{a+1}]$ for each $a \in \mathbb{Z}_k$. We refer to the saddles defining the heteroclinic cycle as nodes. A heteroclinic network is a connected set that is the union of heteroclinic cycles. When a two-dimensional branch of $W^u(P_a)$ coincides with a two-dimensional branch of $W^s(P_{a+1})$, we also refer to it as a two-dimensional connection $[P_a \to P_{a+1}]$. 

[1881]
2.2. Basin of attraction

For a solution of (1.1) passing through $x \in M$, the set of its accumulation points as $t$ goes to $+\infty$ is the \( \omega \)-limit set of $x$ and will be denoted by $\omega(x)$. More formally,

$$\omega(x) = \bigcup_{T=0}^{+\infty} \bigcup_{t>T} \phi(t, x).$$

It is well known that $\omega(x)$ is closed and flow-invariant, and if $M$ is compact, then $\omega(x)$ is non-empty for every $x \in M$. If $\Gamma \subset M$ is a flow-invariant subset for (1.1), the basin of attraction of $\Gamma$ is given by

$$B(\Gamma) = \{ x \in M \setminus \Gamma : \text{all accumulation points of } \phi(t, x) \text{ as } t \to +\infty \text{ lie in } \Gamma \}.$$ 

Note that, with this definition, the set $\Gamma$ is not contained in $B(\Gamma)$.

3. The setting

3.1. The hypotheses

Our object of study is the dynamics around a heteroclinic cycle associated to $k$ periodic solutions, $k \in \mathbb{N}$, $k > 1$, for which we give a rigorous description here. Specifically, we study a one-parameter family of $C^\infty$-vector fields $f_\lambda$ in $\mathbb{R}^3$ whose flow has the following properties (see figure 1):

(P1) For $\lambda \in \mathbb{R}$, there are $k$ hyperbolic periodic solutions $P_a$ of $\dot{x} = f_\lambda(x)$, $a \in \mathbb{Z}_k$, of minimal period $\xi_a > 0$. The Floquet multipliers of $P_a$ are real and given by $e^{\alpha_a} > 1$ and $e^{-\alpha_a} < 1$ where $e_\alpha > e_c > 0$.

(P2) For each $a \in \mathbb{Z}_k$, the manifolds $W^s_{\text{loc}}(P_a)$ and $W^u_{\text{loc}}(P_a)$ are smooth surfaces homeomorphic to a cylinder—see figure 2.

(P3) For each $a \in \mathbb{Z}_k$, and for $\lambda = 0$, one branch of $W^s(P_a)$ coincides with a branch of $W^r(P_{a+1})$, forming a heteroclinic network, that we call $\Gamma_0$ and whose basin of attraction contains an open set.

(P4) (Transversality) For $\lambda > 0$ and for each $a \in \mathbb{Z}_k$, a branch of the two-dimensional manifold $W^s(P_a)$ intersects transversely a branch of $W^r(P_{a+1})$ at two trajectories, forming a heteroclinic network $\Gamma_\lambda$, consisting of two heteroclinic cycles.
For \( \lambda \neq 0 \), any one of the two trajectories of (P4) in \( W^u(P_0) \cap W^s(P_{a+1}) \) will be denoted by \([P_a \rightarrow P_{a+1}]\). A more technical assumption (P5) will be made in section 4.1 below, after we have established some notation. For \( a \in \mathbb{Z}_k \), define the following constants:

\[
\delta_a = \frac{c_a}{e_a} > 1, \quad \mu_{a+1} = \frac{c_a}{e_{a+1}} \quad \text{and} \quad \delta = \prod_{a=1}^{k} \delta_a > 1 \quad (3.3)
\]

Also denote by \( \mathbf{x}_a \in \mathbb{R}^3 \) the centre of gravity of \( P_a \), given by

\[
\mathbf{x}_a = \frac{1}{\xi_a} \int_0^{\xi_a} \mathbf{P}_a(t) dt \in \mathbb{R}^3.
\]

Without loss of generality we assume that the minimal period \( \xi_a = 2\pi \), for all \( a \in \mathbb{Z}_k \). It will be explicitly used in system (4.4) below.

3.2. The dynamics

The dynamics of this kind of heteroclinic structures involving periodic solutions has been studied before in [1, 3, 21, 27], in different contexts.

Since \( f_0 \) satisfies (P1)–(P3) then, adapting the Krupa and Melbourne criterion [19, 20], any solution starting sufficiently close to \( \Gamma_0 \) will approach it in positive time; in other words \( \Gamma_0 \) is asymptotically stable. As a trajectory approaches \( \Gamma_0 \), it visits one periodic solution, then moves off to visit the other periodic solutions in the network. After a while it returns to visit the initial periodic solution, and the second visit lasts longer than the first. The oscillatory regime of such a solution seems to switch into different nodes, at geometrically increasing times.

For \( \lambda \neq 0 \), by (P4), the invariant manifolds of the nodes meet transversally, and the network is no longer asymptotically stable due to the presence of suspended horseshoes in its neighbourhood. As proved in [27], there is an infinite number of heteroclinic and homoclinic connections between any two periodic solutions and the dynamics near the heteroclinic network is very complex. The route to chaos corresponds to an interaction of robust switching with chaotic cycling. The emergence of chaotic cycling does not depend on the magnitude of the multipliers of the periodic solutions. It depends only on the geometry of the flow near the cycle.
In table 1, we summarise some information about the type of heteroclinic structure of $\Gamma_\lambda$ and the type of dynamics nearby.

### 4. Local and global dynamics near the network

Given a heteroclinic network of periodic solutions $\Gamma_\lambda$ with nodes $P_a \in \mathbb{Z}_k$, let $V_\lambda$ be a compact neighbourhood of $\Gamma_\lambda$ and let $V_a$ be pairwise disjoint compact neighbourhoods of the nodes $P_a$ such that each boundary $\partial V_a$ is a finite union of smooth manifolds with boundary, that are transverse to the vector field everywhere, except at their boundary. Each $V_a$ is called an **isolating block** for $P_a$ and, topologically, it consists of a hollow cylinder. Topologically, $V_\lambda$ may be seen as a solid torus with genus $k$ (see Table 1).

#### 4.1. Suspension and local coordinates

For $a \in \mathbb{Z}_k$, let $\Sigma_a$ be a cross section transverse to the flow at $P_a \in \Sigma_a$. Since $P_a$ is hyperbolic, there is a neighbourhood $\ast V_a$ of $P_a$ in $\Sigma_a$ where the first return map to $\Sigma_a$, denoted by $\pi_a$, is $C^1$ conjugate to its linear part. Moreover, for each $r \geq 2$ there is an open and dense subset of $\mathbb{R}^2$ such that, if the eigenvalues $(\alpha_a, \epsilon_a)$ lie in this set, then the conjugacy is of class $C^r$—see [32] and appendix A. The eigenvalues of $\pi_a$ are $e^{\alpha_a}$ and $e^{-\alpha_a}$. Suspending the linear map gives rise, in cylindrical coordinates $(\rho, \theta, z)$, to the system of differential equations:

\[
\begin{align*}
\dot{\rho} &= -\epsilon_a(\rho - 1) \\
\dot{\theta} &= 1 \\
\dot{z} &= \epsilon_a z
\end{align*}
\]

which is $C^2$-conjugate, after reparametrising the time variable, to the original flow near $P_a$. In these coordinates, the periodic solution $P_a$ is the circle defined by $\rho = 1$ and $z = 0$, its local stable manifold, $W_{loc}^{s}(P_a)$, is the plane defined by $z = 0$ and $W_{loc}^{u}(P_a)$ is the surface defined by $\rho = 1$ as in figure 2.

We will work with a hollow three-dimensional cylindrical neighbourhood $V_a(\epsilon)$ of $P_a$ contained in the suspension of $V_a$ given by:

\[ V_a(\epsilon) = \{(\rho, \theta, z) : 1 - \epsilon \leq \rho \leq 1 + \epsilon, \quad -\epsilon \leq z \leq \epsilon \quad \text{and} \quad \theta \in \mathbb{R} \quad \text{(mod } 2\pi\text{)}\}. \]

When there is no ambiguity, we write $V_a$ instead of $V_a(\epsilon)$. Its boundary is a disjoint union

\[ \partial V_a = \text{Int}(P_a) \cup \text{Out}(P_a) \cup \Omega(P_a) \]

such that:

- $\text{Int}(P_a)$ is the union of the walls, defined by $\rho = 1 \pm \epsilon$, of the cylinder, locally separated by $W^s(P_a)$. Trajectories starting at $\text{Int}(P_a)$ go inside the cylinder $V_a$ in small positive time.

| $\lambda$ | Structure of $V_\lambda$ | Dynamics near $\Gamma_\lambda$ | References |
|-----------|--------------------------|-------------------------------|------------|
| Zero      | Torus of genus $k$       | Attractor                     | [21, 27]   |
| Non-zero  | Torus of genus $\neq k$  | Chaos (Switching and Cycling) | [1, 3, 27] |
\textbullet \ Out(P_0) is the union of two anuli, the top and the bottom of the cylinder, defined by $z = \pm \varepsilon$, locally separated by $W^u(P_0)$. Trajectories starting at $Out(P_0)$ go inside the cylinder $V_a$ in small negative time.

\textbullet \ The vector field is transverse to $\partial V_a$ at all points except possibly at the four circles: $\Omega(P_0) = \text{In}(P_0) \cap \text{Out}(P_0)$.

The two cylinder walls, $\text{In}(P_0)$ are parametrised by the covering maps:

$$(\theta, z) \mapsto (1 \pm \varepsilon, \theta, z) = (\rho, \theta, z),$$

where $\theta \in \mathbb{R}$ (mod $2\pi$), $|z| < \varepsilon$. In these coordinates, $\text{In}(P_0) \cap W^u(P_0)$ is the union of the two circles $z = 0$. The two anuli $Out(P_0)$ are parametrised by the coverings:

$$(\varphi, r) \mapsto (r, \varphi, \pm \varepsilon) = (\rho, \theta, z),$$

for $1 - \varepsilon < r < 1 + \varepsilon$ and $\varphi \in \mathbb{R}$ (mod $2\pi$) and where $Out(P_0) \cap W^s(P_0)$ is the union of the two circles $r = 1$. In these coordinates $\Omega(P_0) = \text{In}(P_0) \cap \text{Out}(P_0)$ is the union of the four circles defined by $\rho = 1 \pm \varepsilon$ and $z = \pm \varepsilon$.

The portion of the unstable manifold of $P_2$ that goes from $P_2$ to $\text{In}(P_{a+1})$ without intersecting $V_{a-1}$ will be denoted $W^{u}_{\text{loc}}(P_2)$. Similarly, $W^{s}_{\text{loc}}(P_2)$ will denote the portion of the stable manifold of $P_2$ that is outside $V_{a-1}$ and goes directly from $Out(P_{a-1})$ to $P_2$. With this notation, we formulate the following technical condition:

(P5) For $a \in \mathbb{Z}_k$, and $\lambda = 0$ close to zero, the manifolds $W^{u}_{\text{loc}}(P_2)$ intersect the cylinders $In(P_{a+1})$ on a closed curve. Similarly, $W^{s}_{\text{loc}}(P_2)$ intersects the annulus $Out(P_{a-1})$ on a closed curve.

The previous hypothesis complements (P4) and corresponds to the expected unfolding from the coincidence of the manifolds $W^u(P_{a+1})$ and $W^s(P_a)$ at $f_0$, see Chilingworth [5]. Note that (P4) and (P5) are satisfied in an open subset of the set of unfoldings $f_\lambda$ of $f_0$ satisfying (P1)–(P3).

In order to distinguish the local coordinates near the periodic solutions, we sometimes add the index $a$ with $a \in \mathbb{Z}_k$.

### 4.2. Local map near the periodic solutions

For each $a \in \mathbb{Z}_k$, we may solve (4.4) explicitly, then we compute the flight time from $\text{In}(P_a)$ to $Out(P_a)$ by solving the equation $z(t) = \varepsilon$ for the trajectory whose initial condition is $(\theta_a, z_a) \in \text{In}(P_a) \setminus W^u(P_a)$, with $z_a > 0$. We find that this trajectory arrives at $Out(P_a)$ at a time $\tau_a : \text{In}(P_a) \setminus W^u(P_a) \to \mathbb{R}_+$ given by:

$$\tau_a(\theta_a, z_a) = \frac{1}{e_a} \ln \left( \frac{\varepsilon}{z_a} \right).$$

Replacing this time in the other coordinates of the solution, yields:

$$\Phi_a(\theta_a, z_a) = \left( \theta_a - \frac{1}{e_a} \ln \left( \frac{z_a}{\varepsilon} \right), 1 \pm \varepsilon \left( \frac{z_a}{\varepsilon} \right)^{\delta_a} \right) = (\varphi_a, r_a) \quad \text{where} \quad \delta_a = \frac{e_a}{r_a} > 1.$$  

The signs $\pm$ depend on the component of $\text{In}(P_a)$ we started at, $+$ for trajectories starting with $r_a > 1$ and $-$ for $r_a < 1$. We will discuss the case $r_a > 1$, $z_a > 0$, the behaviour on the other components is analogous.
4.3. Flight times for $\lambda = 0$

Here we introduce some terminology that will be used in section 5; see figure 3. For $X \in B(\Gamma_0)$, let $T_1(X)$ be the smallest $t \geq 0$ such that $\phi(t, X) \in \text{In}(\mathcal{P}_0)$, where $\mathcal{P}_0$ and $\mathcal{P}_k$ represent the same periodic solution.

$$T_1 = 0$$

In order to simplify the computations, we may assume that the transition from $\text{Out}(\mathcal{P}_a)$ to $\text{In}(\mathcal{P}_{a+1})$ is instantaneous. This is reasonable because, as $t \to \infty$, the time of flight inside each $V_a$ tends to infinity, whereas the time of flight from $\text{Out}(\mathcal{P}_a)$ to $\text{In}(\mathcal{P}_{a+1})$ remains limited. In the proof of proposition 1 below, we will see that this assumption does not affect the validity of our results. With this assumption, the time of flight $\tau_{a+nk}(X)$ inside $V_a$ at the $n$-th pass of the trajectory through $V_a$ will be

$$\tau_{a+nk}(X) = T_{a+1+nk}(X) - T_{a+1}(X),$$

thus extending the notation $\tau_a$ introduced in section 4.2 above to $X \in B(\Gamma_0)$ and any index $a + nk \in \mathbb{N}$.

For each $a \in \mathbb{Z}_k$ and for $\lambda = 0$, we define the transition map $\Psi_a^0 : \text{Out}(\mathcal{P}_a) \to \text{In}(\mathcal{P}_{a+1})$

$$\Psi_a^0(q_a, r_a) = (q_a, r_a - 1) = (\theta_{a+1}, z_{a+1}).$$

The transition maps for $\lambda = 0$ will be discussed in section 6.1.

5. The $k$-polygon at the organising centre

Let $f_0$ be a vector field in $\mathbb{R}^3$ satisfying (P1)–(P3). All the results of this section assume $\lambda = 0$. Suppose, from now on, that $\phi(t, X)$ is a solution $\dot{x} = f_0(x)$ with initial condition $X = \phi(0, X)$ in $B(\Gamma_0)$, the basin of attraction of $\Gamma_0$. 

5.1. The statistical limit set of $f_0$

The statistical limit set $\Lambda_{\text{stat}}(f_0)$ associated to the basin of attraction of $\Gamma_0$ is the smallest closed subset where Lebesgue almost all trajectories spend almost all time. More formally, following Ilyashenko [13] and Karabacak and Ashwin [16], we define:

**Definition 2.** For an open set $U \subset \mathbb{R}^3$ and a solution $\phi(t, x)$ of (1.1) with $x \in \mathbb{R}^3$:

1. the frequency of the solution being in $U$ is the ratio:
   \[ \rho_f(x, U, T) = \frac{\text{Leb}\{t \in [0, T] : \phi(t, x) \in U\}}{T}, \]
   where $\text{Leb}$ denotes the Lebesgue measure in $\mathbb{R}$.
2. the statistical limit set, denoted by $\Lambda_{\text{stat}}$, is the smallest closed subset of $\mathbb{R}^3$ for which any open neighbourhood of $U$ of $\Lambda_{\text{stat}}$ satisfies the equality:
   \[ \lim_{t \to +\infty} \rho_f(x, U, t) = 1, \quad \text{for almost all } x \in \mathbb{R}^3. \]

Since the transitions between the saddles of $\Gamma_0$ are very fast compared with the times of sojourn near the periodic solutions $P_a$, $a \in \mathbb{Z}_k$ (see section 4.3) we may conclude that:

**Proposition 1.** Let $f_0$ be a vector field in $\mathbb{R}^3$ satisfying (P1)–(P3). Then:

\[ \Lambda_{\text{stat}}(f_0) = \bigcup_{a=1}^k P_a \subset \Gamma_0. \]

**Proof.** The flow from $\text{Out}(P_a)$ to $\text{In}(P_{a+1})$ is non-singular as in a flow-box. Since both $\text{Out}(P_a)$ and $\text{In}(P_{a+1})$ are compact sets, the time of flight between them has a positive maximum. On the other hand, for each $a \in \mathbb{Z}_k$, the time of flight inside $V_a$ from $\text{In}(P_a) \setminus W^s_{\text{inc}}(P_a)$ to $\text{Out}(P_a)$ tends to infinity as $t$ approach the stable manifold of $P_a$, $W^s_{\text{inc}}(P_a)$, or equivalently as the trajectory accumulates on $\Gamma_0$. □

**Remark 1.** It follows from proposition 1 that, for each $a \in \mathbb{Z}_k$, the time intervals in which trajectories are travelling from $\text{Out}(P_a)$ to $\text{In}(P_{a+1})$ do not affect the accumulation points of the time averages of a solution that is accumulating on $\Gamma_0$. This result will be useful in the proof of the theorem 8 because it shows that the duration of the journeys between nodes may be statistically neglected.

5.2. Estimates of flight times

In this section, we obtain relations between flight times of a trajectory in consecutive isolating blocks as well as other estimates that will be used in the sequel.

**Lemma 2.** For all $j \in \mathbb{N}$ and any initial condition $X \in \mathcal{B}(\Gamma_0)$ we have:

\[ \frac{\tau_{j+1}(X)}{\tau_j(X)} = \frac{c_j}{e_{j+1}}, \quad (5.8) \]

In particular the ratio $\tau_{j+1}(X)/\tau_j(X)$ does not depend on $X$. 

Proof. Given $j \in \mathbb{N}$, let $X_j = (\theta_j, z_j) = \phi(T_j(X), X) \in \mathbb{R}$. Using the expressions (4.5), (4.6) and the expression for $\Psi_j$ in (4.7), we have:

$$
\tau_j + 1(X) = \frac{1}{e_{j+1}} \ln \left( \frac{\varepsilon}{\varepsilon(z_j)} \right) = \frac{1}{e_{j+1}} \delta_j [\ln(e) - \ln(z_j)]
$$

Thus

$$
\tau_j + 1(X) = \frac{1}{e_{j+1}} \delta_j [\ln(e) - \ln(z_j)]
$$

Recall from (3.3) that $\mu_{a+1} = \frac{e_a}{e_{a+1}}, a \in \mathbb{Z}_k$. With this notation we obtain:

**Corollary 3.** For $i, j \in \mathbb{N}$ such that $j > i > 1$, and for any $X \in \mathbb{B}(\Gamma_0)$, we have:

1. $\tau_{j+1}(X) = \prod_{k=1}^{j} \mu_{a+1} = \prod_{k=1}^{j} \delta_j = \delta > 1.$

2. $\tau_{j+1}(X) = \eta(X) \prod_{k=1}^{j} \mu_{a+1}.$

We finish this section with a result comparing the two sequences of times $(\tau_i)_{i \in \mathbb{N}}$ and $(\tau_j)_{j \in \mathbb{N}}$. The proof is very technical and is given in appendix B.1.

**Lemma 4.** For $a \in \mathbb{Z}_k$, and for any $X \in \mathbb{B}(\Gamma_0)$, the following equalities hold:

1. $T_{a+nb}(X) = T_a(X) + \frac{\delta^a - 1}{\delta - 1} \left( \mu_a + \mu_{a+1} + \mu_{a+2} + \ldots + \mu_{a+(b-1)} \right) T_{a-1}(X)$;

2. $T_{a+nb}(X) = T_{a+1+nb}(X) - T_{a+nb}(X) = \delta^a \mu_{a-1}(X)$.

5.3. The vertices of the $k$-polygon

In this section, we show that in $\mathbb{B}(\Gamma_0)$ the time averages fail to converge, by finding several accumulation points for them. For each $a \in \mathbb{Z}_k$, define the point

$$
A_a = \frac{\overline{T_a} + \mu_{a+1} \overline{T_{a+1}} + \mu_{a+2} \overline{T_{a+2}} + \ldots + \prod_{k=1}^{i} \mu_{a+k} \overline{T_{a+k-1}}}{1 + \mu_{a+1} + \mu_{a+2} + \ldots + \prod_{k=1}^{i} \mu_{a+k+1}} = \frac{\text{num}(A_a)}{\text{den}(A_a)}
$$

(5.9)

Note that $A_a$ and $\text{num}(A_a)$ lie in $\mathbb{R}^3$ and $\text{den}(A_a) \in \mathbb{R}$. Later we will see that these points are the vertices of a polygon of accumulation points. First we show that they are accumulation points for the time averages.

**Proposition 5.** Let $a \in \mathbb{Z}_k$, let $f_0$ be a vector field in $\mathbb{R}^3$ satisfying (P1)-(P3) and let $\phi(t, X)$ be a solution of $\dot{x} = f_0(x)$ with $X \in \mathbb{B}(\Gamma_0)$.

$$
\lim_{n \to +\infty} \left[ \frac{1}{T_{a+nb}} \int_0^{T_{a+nb}} \phi(t, X)dt \right] = A_a
$$

In order to prove proposition 5, first we show that it is sufficient to consider the limit when $n \to \infty$ of the averages over one turn around $\Gamma_0$ and then we prove that these averages tend to $A_a$. The proof is divided in two technical lemmas, which may be found in appendix B.2.
5.4. The sides of the $k$-polygon

In section 5.3 we have shown that for $a \in \mathbb{Z}_k$, the time average over the sequences $T_{a+n}k$ of times accumulate, as $n \to \infty$ in the $A_a$. In this section we describe accumulation points for intermediate sequences of times $t_n$. For this, it will be useful to know how $A_a$ and $A_{a+1}$ are related:

**Lemma 6.** For all $a \in \mathbb{Z}_k$, the following equalities hold:

$$
\mu_{a+1} \text{den}(A_{a+1}) = \text{den}(A_a) - (1 - \delta) \quad \text{and} \quad \mu_{a+1} \text{num}(A_{a+1}) = \text{num}(A_a) - (1 - \delta)\bar{a}.
$$

(5.10)

**Proposition 7.** The point $A_{a+1}$ lies in the segment connecting $A_a$ to $\bar{a}$.  

*Proof.* We use lemma 6 to obtain

$$
\text{num}(A_{a+1}) = \frac{1}{\mu_{a+1}} \text{num}(A_a) + \frac{\delta - 1}{\mu_{a+1}} \bar{a}
$$

and hence

$$
A_{a+1} = \frac{\text{num}(A_{a+1})}{\text{den}(A_{a+1})} = \left( \frac{\text{den}(A_a)}{\mu_{a+1} \text{den}(A_{a+1})} \right) \frac{\text{num}(A_a)}{\text{den}(A_a)} + \left( \frac{\delta - 1}{\mu_{a+1} \text{den}(A_{a+1})} \right) \bar{a} = \alpha A_a + \beta \bar{a}.
$$

Again from lemma 6 we have $\text{den}(A_a) = \mu_{a+1} \text{den}(A_{a+1}) - (\delta - 1)$, and therefore

$$
\alpha = \frac{\text{den}(A_a)}{\mu_{a+1} \text{den}(A_{a+1})} = 1 - \frac{\delta - 1}{\mu_{a+1} \text{den}(A_{a+1})} = 1 - \beta
$$

hence $A_{a+1}$ lies in the line through $A_a$ and $\bar{a}$. From the expression in lemma 6 it follows that $\mu_{a+1} \text{den}(A_{a+1}) - \text{den}(A_a) = \delta - 1 < 0$, hence $0 < \alpha < 1$ and thus $A_{a+1}$ lies in the segment from $A_a$ to $\bar{a}$, proving the result. $\square$

We now come to the main result of this section, illustrated in figure 5:

**Theorem 8.** If $f_0$ is a vector field in $\mathbb{R}^3$ satisfying (P1)–(P3), then for any $X \in \mathcal{B}(\Gamma_0)$, the set of accumulation points of the time average $\frac{1}{t} \int_0^t \phi(t,X)dt$ is the boundary of the $k$-polygon defined by $A_1, \ldots, A_k \in \mathbb{R}^3$ in (5.9). Moreover, when $\delta \to 1$ the polygon collapses into a point.

*Proof.* First we show that all points in the boundary of the polygon are accumulation points. Given $L \in [0, 1]$ and $a \in \mathbb{Z}_k$, consider the sequence $t_n = T_{a+n}k + L_{a+n}k$, we want the accumulation points of $\mathcal{L}_n = \frac{1}{t_n} \int_0^{t_n} \phi(t,X)dt$ as $n \to \infty$. For this we write

$$
\mathcal{L}_n = \frac{1}{t_n} \int_0^{t_n} \phi(t,X)dt = \frac{1}{t_n} \int_0^{T_{a+n}k} \phi(t,X)dt + \frac{1}{t_n} \int_{T_{a+n}k}^{t_n} \phi(t,X)dt
$$

$$
= \alpha_n \left( \frac{1}{T_{a+n}k} \int_0^{T_{a+n}k} \phi(t,X)dt \right) + \beta_n \left( \frac{1}{t_n - T_{a+n}k} \int_{T_{a+n}k}^{t_n} \phi(t,X)dt \right),
$$

where

$$
0 < \alpha_n = \frac{T_{a+n}k}{t_n} \leq 1, \quad 0 \leq \beta_n = \frac{t_n - T_{a+n}k}{t_n} \leq 1 \quad \text{and} \quad \alpha_n + \beta_n = 1.
$$
Since both \( \alpha_n \) and \( \beta_n \) are limited, each one of them contains a converging subsequence. We analyse separately each of the terms in the expression for \( L_n \) above. We have already seen in proposition 5 that, if \( B \in \Gamma X_0 \), then.

\[
\int \phi = \infty \quad \text{if} \quad L_n \to \infty \quad \text{for} \quad L = 0.
\]

In particular, if \( L = 0 \), then \( \alpha_n = 1, \beta_n = 0 \) and \( \lim_{n \to \infty} L_n = A_o \).

We claim that if \( L \neq 0 \), then \( \int \phi = \infty \), and \( \lim_{n \to \infty} \phi(t, X) = \infty \). To see this, note that \( \phi(t, X) \in V_0 \) for \( t \in [t_n, t_{n+1}] \). Moreover, since \( \lim_{n \to \infty} \tau_n = \infty \), then for large \( n \), we have that \( t_n - t_{n+1} = \tau_n \) is much larger than \( \tau_o \), the period of \( \mathcal{P}_o \). Since \( X \in \mathcal{B}(I_o) \), then \( \phi(t, X) \) tends to \( \tau_o \) when \( n \to \infty \) and the average of \( \phi(t, X) \) tends to \( \tau_o \), the average of \( \mathcal{P}_o \).

At this point we have established that any accumulation point of \( L_n \) lies in the segment connecting \( A_o \) to \( \tau_o \). We have shown in proposition 7 that this segment also contains \( A_{o+1} \). By proposition 5 we have that \( \lim_{n \to \infty} L_n = A_{o+1} \) for \( L = 1 \). On the other hand, \( \beta_n \) is an increasing function of \( L \), so, as \( L \) increases from 0 to 1, the accumulation points of \( L_n \) move from \( A_o \) to \( A_{o+1} \) in the segment connecting them.

Conversely, any accumulation point lies on the boundary of the polygon. To see this, let \( A \) be an accumulation point of the time average. This means that there is an increasing sequence of times \( s_n \), tending to infinity, and such that \( \lim_{n \to \infty} L_n = A \), where \( L_n = \frac{1}{s_n} \int_{s_n}^{s_{n+1}} \phi(t, X) \)dt. Since \( s_n \) tends to infinity, then it may be partitioned into subsequences of the form \( s_n = T_o + k \tau_n + k \) for each \( a \in Z_k \), and some \( L_{n_j} \in [0, 1] \), as shown in figure 4. The arguments above, applied to this subsequence, show that the accumulation points of \( L_{n_j} \) lie in the segment connecting \( A_o \) to \( A_{o+1} \). Therefore, since \( L_n \) converges, there are two possibilities. The first is that all the \( s_n \) (except possibly finitely many) are of the form above for a fixed \( a \in Z_k \), and hence \( A \) lies in the the segment connecting \( A_o \) to \( A_{o+1} \). The second possibility is that all the \( s_n \) (except maybe a finite number) are of one of the forms

\[
s_n = T_o + n \tau_n \quad \text{or} \quad s_n = T_o + 1 + n \tau_n + n \tau_k.
\]
and that \( A = A_{a+1}. \) In both cases, the accumulation point of the time average will lie on the boundary of the polygon. Finally, when \( \delta \rightarrow 1, \) the expressions (5.10) in lemma 6 become

\[
\mu_{a+1} \text{den}(A_{a+1}) = \frac{\text{num}(A_{a+1})}{\text{den}(A_{a+1})}, \quad \mu_{a+1} \text{num}(A_{a+1}) = \text{num}(A_{a+1}),
\]

hence

\[
A_a = \frac{\text{num}(A_{a})}{\text{den}(A_{a})} = \frac{\mu_{a+1} \text{num}(A_{a+1})}{\mu_{a+1} \text{den}(A_{a+1})} = A_{a+1}
\]

and the polygon collapses to a point at the same time as \( \Gamma_0 \) stops being attracting. \( \square \)

Taking the observable as the projection on any component, the first main result of this paper may be stated as:

**Corollary 9.** If \( f_0 \) is a vector field in \( \mathbb{R}^3 \) satisfying (P1)–(P3), then all points in the basin of attraction of \( \Gamma_0 \) have historic behaviour. In particular the set of initial conditions with historic behaviour has positive Lebesgue measure.

The points of \( \Gamma_0 \) do not have historic behaviour. Indeed, if \( X \in \Gamma_0 \) then either \( X \in \mathcal{P}_a \) or \( \phi(t, X) \) accumulates on \( \mathcal{P}_a \) for some \( a \in \{1, \ldots, k\}. \) In both cases, \( \lim_{t \to \infty} \frac{1}{T} \int_0^T \phi(t, X) dt = \Gamma_a. \)

The previous proofs have been done for a piecewise continuous trajectory; when \( t = T, \) the trajectory jumps from \( V_{a-1} \) to \( V_a, \) whereas the real solutions have a continuous motion from \( V_{a-1} \) to \( V_a \) along the corresponding heteroclinic connection, during a bounded interval of time. As shown in proposition 1, the statistical limit set of \( \Gamma_0 \) is \( \bigcup_{a=1}^k \mathcal{P}_a \) meaning that trajectories spend Lebesgue almost all time near the periodic solutions, and not along the connections. Therefore, the intervals in which the transition occurs do not affect the accumulation points of the time averages of the trajectories and the result that was shown for a piecewise continuous trajectory holds.

### 6. Persistence of historic behaviour

From now on, we discuss the differential equation \( \dot{x} = f_0(x) \) satisfying (P1)–(P5), with \( \lambda \neq 0. \) In this case it was shown in Rodrigues et al [27] that the simple dynamics near \( \Gamma_0 \) jumps to chaotic behaviour near \( \Gamma_\lambda. \)

#### 6.1. Invariant manifolds for \( \lambda > 0 \)

We describe the geometry of the two-dimensional local invariant manifolds of \( \mathcal{P}_a \) and \( \mathcal{P}_{a+1} \) for \( \lambda \neq 0, \) under the assumptions (P1)–(P5). For this, let \( f_0 \) be an unfolding of \( f_0 \) satisfying (P1)–(P5). For \( \lambda \neq 0, \) we introduce the notation:

- \( (O_a^1, 0) \) and \( (O_a^2, 0) \) with \( 0 < O_a^1 < O_a^2 < 2\pi \) are the coordinates of the two points where the connections \( \mathcal{P}_a \to \mathcal{P}_{a+1} \) of Properties (P4)–(P5) meet \( \text{Out}(\mathcal{P}_a); \)
- \( (I_a^1, 0) \) and \( (I_a^2, 0) \) with \( 0 < I_a^1 < I_a^2 < 2\pi \) are the coordinates of the two points where \( \mathcal{P}_{a-1} \to \mathcal{P}_a \) meets \( \text{In}(\mathcal{P}_a); \)
- \( (O_a^1, 0) \) and \( (I_a^1, 0) \) are on the same trajectory for each \( i \in \{1, 2\} \) and \( a \in \mathbb{Z}. \)

By (P5), for small \( \lambda > 0, \) the curves \( W_{\text{loc}}(\mathcal{P}_{a+1}) \cap \text{Out}(\mathcal{P}_a) \) and \( W_{\text{loc}}(\mathcal{P}_a) \cap \text{In}(\mathcal{P}_{a+1}) \) can be seen as graphs of smooth periodic functions, for which we make the following conventions (see figure 6):
\[ PP \cap + W \text{Out} \] is the graph of \( \phi = \lambda g a \), with \( \phi = \lambda g a i \), for \( \{ \} \in i 1, 2 \) and \( \in a Z k \).

\[ PP \cap - W \text{In} \] is the graph of \( \theta = \lambda y h a \), with \( \theta = \lambda y h 0 a a i \), for \( \{ \} \in i 1, 2 \) and \( \in a Z k \).

omitting the superscript \( \lambda \), we have:

\[ \phi >' hI 0 a a 1, \phi <' hI 0 a a 2, \phi >' gO 0 a a 2 \text{and } \phi <' gO 0 a a 1, \text{ for } \{ \} \in i 1, 2 . \]

The two points \((0,0)\) and \((0,0)\) divide the closed curve \( PP \cap + W \text{Out} \) in two components, corresponding to different signs of \( r a - 1 \). With the conventions above, we get \( g^3(\varphi) > 1 \) for \( \varphi \in (O_a^1, O_a^2) \). More specifically, the region in \( \text{Out}(P_a) \) between \( W^t_{\text{loc}}(P_{a+1}) \) and \( W^s_{\text{loc}}(P_a) \) given by

\[ A = \{ (\varphi^i, r_a) \in \text{Out}(P_a) : 1 < r_a < g^3(\varphi^i) \} \]

is mapped by \( \Psi_d \) into the lower \((z_a < 0)\) part of \( \text{In}(P_{a+1}) \). Similarly, the region

\[ B = \{ (\varphi^i, r_a) \in \text{Out}(P_a) : r_a > 1 \} \setminus A = \{ (\varphi^i, r_a) \in \text{Out}(P_a) : 1 < r_a \text{ and } g^3(\varphi^i) < r_a \} \]

(see figure 7) is mapped into the \( z_a > 0 \) component of \( \text{In}(P_{a+1}) \).

Figure 5. The polygon in theorem 8 with \( k = 3 \): the accumulation points of the time average \( \frac{1}{T} \int_0^T \phi(t, x) \text{d}t \) lie on the boundary of the triangle defined by \( A_1, A_2 \) and \( A_3 \).

Figure 6. For \( \lambda \) close to zero, both \( W^t_{\text{loc}}(P_{a+1}) \cap \text{Out}(P_a) \) and \( W^s_{\text{loc}}(P_a) \cap \text{In}(P_{a+1}) \) are closed curves, given in local coordinates as the graphs of periodic functions; this is the expected unfolding from the coincidence of the invariant manifolds at \( \lambda = 0 \).

- \( W^t_{\text{loc}}(P_{a+1}) \cap \text{Out}(P_a) \) is the graph of \( y = g^i_a(\varphi) \), with \( g^i_a(O_a^i) = 1 \), for \( i \in \{1, 2\} \) and \( a \in \mathbb{Z}_k \).
- \( W^s_{\text{loc}}(P_{a-1}) \cap \text{In}(P_a) \) is the graph of \( y = h^i_a(\theta) \), with \( h^i_a(T_a^i) = 0 \), for \( i \in \{1, 2\} \) and \( a \in \mathbb{Z}_k \).
- omitting the superscript \( \lambda \), we have: \( h^i_a(T_a^i) > 0 \), \( h^i_a(T_a^i) < 0 \), \( g^i_a(O_a^i) > 0 \) and \( g^i_a(O_a^i) < 0 \), for \( i \in \{1, 2\} \).
The maximum value of \( \phi \) is attained at some point \((\phi_\lambda, r_\lambda)\), with \( a_0 < r_\lambda < b_0 \). We denote by \( M_a^k(\lambda) \) the maximum value of \( h_a^\lambda \).

6.2. Geometrical preliminaries

We will need to introduce some definitions.

**Definition 3.** A spiral on the annulus \( A \) accumulating on the circle \( r = \nu \) is a curve on \( A \) (see figure 8), without self-intersections, that is the image, by the parametrisation \((\phi, r)\) of the annulus, of a continuous map \( H : (b, c) \to \mathbb{R} \times [0, 1] \),

\[
H(s) = (\phi(s), r(s)),
\]

such that:

(i) there are \( \tilde{b} \leq \tilde{c} \in (b, c) \) for which both \( \phi(s) \) and \( r(s) \) are monotonic in each of the intervals \((b, \tilde{b})\) and \((\tilde{c}, c)\);

(ii) either \( \lim_{s \to b^+} \phi(s) = +\infty \) or \( \lim_{s \to b^+} \phi(s) = -\infty \), \( \lim_{s \to c^-} \phi(s) = -\infty \), \( \lim_{s \to c^-} r(s) = \nu \).

As shown in figure 8, it follows from the assumptions on the function \( \phi(s) \) that it has either a global minimum or a global maximum, and that \( r(s) \) always has a global maximum. The point where the map \( \phi(s) \) has a global minimum or a global maximum will be called a fold point of the spiral. The global maximum value of \( r(s) \) will be called the maximum radius of the spiral.

6.3. Geometry of the transition maps \( \Phi_a \)

**Proposition 10.** Under the conventions of section 6.1, for each \( a \in \mathbb{Z}_b \), the local map \( \Phi_a \) transforms the part of the graph of \( h_a \) with \( P_a \) into a spiral on Out\( (P_a) \) accumulating on the circle Out\( (P_a) \cap W^u_{\text{out}}(P_a) \). This spiral has maximum radius \( 1 + e^{1 - \epsilon(M_a^k)_{\epsilon}} \); it has a fold.
point that, as $\lambda$ tends to zero, turns around $\text{Out}(P_a)$ infinitely many times.

**Proof.** The curve $\Phi_{a}(W^{u}_{\text{loc}}(P_{a-1}) \cap \text{In}(P_{a}))$ is given by $H_{a}(\theta) = \Phi_{a}(\theta, h_{a}(\theta)) = (\varphi_{a}(\theta), r_{a}(\theta))$ where:

$$H_{a}(\theta) = \Phi_{a}(\theta, h_{a}(\theta)) = \left(\theta - \frac{1}{\epsilon_{a}} \ln \left(\frac{h_{a}(\theta)}{\epsilon}\right), 1 + \epsilon \left(\frac{h_{a}(\theta)}{\epsilon}\right)^{\delta}\right) = (\varphi_{a}(\theta), r_{a}(\theta)).$$

From this expression it follows immediately that

$$\lim_{\theta \to \tilde{I}_{a}} \varphi_{a}(\theta) = \lim_{\theta \to \tilde{I}_{a}} \varphi_{a}(\theta) = +\infty \quad \text{and} \quad \lim_{\theta \to \tilde{I}_{a}} r_{a}(\theta) = \lim_{\theta \to \tilde{I}_{a}} r_{a}(\theta) = 1$$

hence, conditions (ii) and (iii) of the definition of spiral hold. Condition (i) holds trivially near $I_{a}^0$ since $h_{a}'(I_{a}^0) < 0$, hence there is $\tilde{I}_{a} < I_{a}^0$ such that $\varphi_{a}'(\theta) > 1$ for all $\theta \in (\tilde{I}_{a}, I_{a}^0)$. On the other hand, since $h_{a}'(I_{a}^1) > 0$ and $\lim_{\theta \to I_{a}^1} h_{a}(\theta) = 0$, there is $I_{a}^1 < \theta_{a}^M$, where $\varphi_{a}'(\theta) < 0$ for all $\theta \in (I_{a}^1, \theta_{a}^M)$.

The statement about the maximum radius follows immediately from (6.11) and the conventions of section 6.1.

6.4. A set of one-parameter families of vector fields

For any unfolding $f_{a}$ of $f_{0}$, as we have seen in sections 6.1 and 6.3, the maximum radius $M_{a}^{0}(\lambda)$ of $W^{u}_{\text{loc}}(P_{a+1}) \cap \text{Out}(P_{a})$, and the maximum height $M_{a}^{1}(\lambda)$ of $W^{u}_{\text{loc}}(P_{a-1}) \cap \text{In}(P_{a})$, satisfy:

$$\lim_{\lambda \to 0} M_{a}^{1}(\lambda) = 0 \quad \lim_{\lambda \to 0} (1 + \epsilon^{1-\delta}(M_{a}^{1}(\lambda))^\delta) = \lim_{\lambda \to 0} M_{a}^{0}(\lambda) = 1.$$

We make the additional assumption that $1 + \epsilon^{1-\delta}(M_{a}^{1}(\lambda))^\delta$ tends to zero faster than $M_{a}^{0}(\lambda)$ for at least one $a \in \mathbb{Z}_{k}$. This condition defines the open set $C$ of generic unfoldings $f_{a}$ that we need for the statement of theorem 11. More precisely,

$$C = \{ f_{a} \text{ satisfying (P1) -- (P5)} : \exists a \in \mathbb{Z}_{k} \exists \lambda_{0} > 0 : 0 < \lambda < \lambda_{0} \Rightarrow 1 + \epsilon^{1-\delta}(M_{a}^{1}(\lambda))^\delta < M_{a}^{0}(\lambda)\}.$$

(6.12)

The set $C$ is open in the Whitney $C^{2}$ topology.

6.5. Heteroclinic tangencies

**Theorem 11.** For any family $f_{a}$ of vector fields in the set $C$ defined in (6.12) there is $a \in \mathbb{Z}_{k}$ such that:

(a) there is a sequence $\lambda_{i} > 0$ of real numbers with $\lim_{i \to \infty} \lambda_{i} = 0$ such that for $\lambda = \lambda_{i}$ the
manifolds $W^u(P_{a-1})$ and $W^p(P_{a+1})$ are tangent; for $\lambda > \lambda_c$ there are two heteroclinic connections in $W^u(P_{a-1}) \cap W^p(P_{a+1})$ that collapse into the tangency at $\lambda = \lambda_c$ and then disappear for $\lambda < \lambda_c$;

(b) arbitrarily close to the connection $[P_{a-1} \to P_a]$ there are hyperbolic periodic solutions at points $x_i$ and infinitely many values $\lambda_n$, for which the periodic solution has a homoclinic tangency of its invariant manifolds.

Note that for $k = 2$, the tangency of assertion (a) is a homoclinic connection.

**Proof.** Let $\theta_0 = \theta^*_{\lambda_c}(\lambda)$ correspond to a fold point of the spiral $\Phi_{\lambda_c}(W^u(P_{a-1}) \cap \text{In}(P_a))$ given by (6.11). Since $f_\lambda \in C$ and using proposition 10 and (6.12), for $\lambda < \lambda_0$ all points in the spiral have second coordinate less than $M^{\theta^*}_\lambda$, this is true, in particular, for the fold point $H_\lambda(\theta^*_{\lambda_c}(\lambda))$.

Also by proposition 10 the fold point turns around $\text{Out}(P_a)$ infinitely many times as $\lambda$ goes to zero. This means that there is a positive value $\lambda_0 < \lambda_0$ such that $H_\lambda(\theta^*_{\lambda_c}(\lambda))$ lies in the region $A$ that will be mapped to $z_0 < 0$ (see section 6.1) and there is a positive value $\lambda_B < \lambda_0$ such that $H_\lambda(\theta(\lambda_0))$ lies in the region $B$ that goes to $z_0 > 0$, as in figure 9. Therefore, the curve $H_\lambda(\theta_0(\lambda))$ is tangent to the graph of $g^3_\lambda$ at some point $H_\lambda(\theta^*_{\lambda_c}(\lambda))$ with $\lambda_0 < \lambda_B < \lambda_0$.

As $\lambda$ decreases from $\lambda_B$, the fold point enters and leaves the region $A$, creating a sequence of tangencies to the graph of $g^3_\lambda$. At each tangency, two points where $H_\lambda(\theta^*_{\lambda_c}(\lambda))$ intersects the graph of $g^3_\lambda$ come together, corresponding to the pair of transverse heteroclinic connections that collapse at the tangency. This completes the proof of (a).

For assertion (b), note that by the results of [27] there is a suspended horseshoe near the connection $[P_{a-1} \to P_a]$. Hence, there are hyperbolic fixed points of the first return map to $\text{In}(P_{a-1})$ arbitrarily close to the connection; let $p_i$ be one of them. Denote by $\eta_i$ the map $\Psi_0 \circ \Phi_{\lambda_c}$. The image by $\Phi_{\lambda_c}$ of an interval contained in $W^u(p_i)$ accumulates on $W^p(P_{a-1})$. In particular, it is mapped by $\eta_i \circ \Phi_{\lambda_c-1}$ into infinitely many spirals in $\text{Out}(P_a)$, each one having a fold point—see figure 10. Since the fold points turn around $\text{Out}(P_{a+1})$ infinitely many times as $\lambda$ varies, this curve is tangent to $W^p(p_i)$ at a sequence $\lambda_{n,i}$ of values of $\lambda$.

The hypothesis (P3) in the definition of $C$ for theorem 11, that the family $f_\lambda$ unfolds the degeneracy $f_0$, may be replaced by the assumption that the flow of $f_0$ turns in opposite directions around two successive nodes $P_a$ and $P_{a+1}$, as in [14], i.e. by the assumption that two successive nodes have different chirality. This is because, in the proof of theorem 11, the heteroclinic
tangency is obtained from the presence of a fold point in the curve \( \Phi(\mathbb{P}_\text{in} \cap \mathbb{W}_\text{loc} \cap \mathbb{P}_\text{out}) \) and from the control of the angular coordinate \( \varphi \) of the fold. This is the content of proposition 10, where we use the fact that \( \mathbb{P}_\text{in} \cap \mathbb{W}_\text{loc} \cap \mathbb{P}_\text{out} \) is the graph of a function with a maximum, a consequence of (P3) and (P4). If we assume instead that successive nodes have different chirality as in [14], then the image by \( \Phi \) of the curve \( \mathbb{P}_\text{in} \cap \mathbb{W}_\text{loc} \cap \mathbb{P}_\text{out} \) will have infinitely many fold points whose coordinates \( \varphi \) will form a dense subset of \( [0, 2\pi] \), and hence, as in [14], an arbitrarily small change in the parameter \( \lambda \) will create a heteroclinic tangency.

6.6. Historic behaviour

The next result is the core of this section. It locates trajectories with historic behaviour \( C^2 \)-close to the unfolding of a degenerate equation, as a consequence of the tangencies found in theorem 11.

**Theorem 12.** For any family \( f_\lambda \) of vector fields in the open set \( \mathcal{C} \) defined in (6.12) there are sequences \( 0 < \xi_i < \zeta_i < \xi_{i+1} \) with \( \lim_{i \to +\infty} \zeta_i = 0 \), such that for each \( \lambda \) in \( (\xi_i, \zeta_i) \), there are vector fields arbitrarily close to \( f_\lambda \) in the \( C^2 \)-topology for which there is an open set of initial conditions with historic behaviour.

In the proof we will use the following concept:

**Definition 4.** Let \( M \) be a smooth surface and let \( \text{Diff}^r(M) \) be the set of its local diffeomorphisms of class \( C^r \), \( r \geq 2 \). An open subset \( \mathcal{N} \subset \text{Diff}^r(M) \) is a Newhouse domain if any element of \( \mathcal{N} \) is \( C^r \)-approximated by a diffeomorphism \( g \) with a homoclinic tangency associated with a dissipative saddle fixed point \( p_g \), and moreover \( g \) has a \( C^r \)-persistent tangency associated with some basic sets \( \Lambda_g \) containing \( p_g \) in the sense that there is a \( C^r \)-neighbourhood of \( g \) any element of which has a homoclinic tangency for the continuation of \( \Lambda_g \).

Newhouse has shown in [22] that any \( C^r \) diffeomorphism containing a homoclinic tangency to a dissipative saddle point lies in the closure of a Newhouse domain in the \( C^2 \) topology.

We will need the definition of historic behaviour for diffeomorphisms:

**Definition 5.** Let \( F \) be a \( C^2 \) diffeomorphism on a smooth surface \( M \). We say that the forward orbit \( \{ x, F(x), F^2(x), \ldots, F^n(x), \ldots \} \) has historic behaviour if the average

\[
\frac{1}{n+1} \sum_{j=0}^{n} \delta_{F^j(x)} \tag{6.13}
\]

does not converge as \( n \to +\infty \) in the weak topology, where \( \delta_Z \) is the Dirac measure on \( M \) supported at \( Z \in \mathbb{M} \).
Proof of theorem 12. For $\lambda = 0$ and $a \in \mathbb{Z}$, the derivative of the first return map to $\text{In}(P_a)$ has determinant of the form $Cz_a^{-1}$ for some constant $C > 0$. Thus, for sufficiently small $\lambda > 0$, and at points near $W'(P_a)$, the first return map to $\text{In}(P_a)$ is also contracting, since the determinant of its derivative has absolute value less than 1. Moreover, the family $f_0$ unfolds each one of the homoclinic tangencies of theorem 11 generically. Hence the arguments of Newhouse, Palis et al [22, 23, 35] revived in [15] may be applied here to show that near each one of the homoclinic tangencies there is a sequence of intervals $(\xi, \zeta)$ in the set of parameters $\lambda$ corresponding to a Newhouse domain.

By theorem A of Kiriki & Soma [17], each Newhouse domain for the first return map is contained in the closure of the set of diffeomorphisms having an open set of points with historic behaviour. By theorem 11 the family $f_0$ unfolds the heteroclinic tangencies generically. Hence, from the results of [17], it follows that for each $\lambda \in (\xi, \zeta)$, the first return map $F_0^k$ may be approximated in the $C^2$ topology by maps $\tilde{F}$ defined in $\text{In}(P_a)$ for which we may find an open connected subset $\mathcal{U} \subset \text{In}(P_a)$ and two sequences of integers, $(a_j)_{j \in \mathbb{N}}$ and $(b_j)_{j \in \mathbb{N}}$, such that, for each $x \in \mathcal{U}$, the limits (6.13) for $\tilde{F}$ are different for $n$ in the two sequences. In particular, there exists a set $A \subset \text{In}(P_a)$, such that

$$\forall x \in \mathcal{U}, \quad \lim_{k \to +\infty} \frac{1}{a_k + 1} \sum_{j=0}^{a_k} \delta F^k(x)(A) = \lim_{k \to +\infty} \frac{1}{b_k + 1} \sum_{j=0}^{b_k} \delta F^k(x)(A)$$

or, equivalently,
∀x ∈ U, \[
L = \lim_{k \to +\infty} \frac{1}{a_k + 1} \sum_{j=0}^{a_k} \chi_A(F^j(x)) \approx \lim_{k \to +\infty} \frac{1}{b_k + 1} \sum_{j=0}^{b_k} \chi_A(F^j(x)) = \tilde{L}
\] (6.14)

where \(\chi_A\) denotes the characteristic function on \(A\). According to the proof of [17], the two fixed points of the horseshoe that arises near the tangency will be visited by orbits of points in the set \(U\).

Since the maps \(\tilde{F}\) are close to the first return map in the \(C^2\) topology, they may be seen as the first return maps to a vector field \(g\) that is \(C^2\)-close to \(f_\lambda\)—see, for instance remark 2 in Pugh and Robinson [25, section 7A]. It remains to show that solutions to \(\dot{x} = g(x)\) have historic behaviour in the sense of definition 1.

Let \(\tau(x)\) be the time of first return of \(x \in \text{In}(\mathcal{P}_g)\), i.e. \(\tau(x) > 0\) and \(\phi(\tau(x), x) \in \text{In}(\mathcal{P}_g)\) where \(\phi\) is the flow associated to \(\dot{x} = g(x)\). Since \(U\) is connected, taking its closure \(\overline{U}\) compact and sufficiently small, \(\tau(x)\) is approximately constant on \(U\). Rescaling the time \(t\) we may suppose \(\tau(x) \equiv 1\).

Given \(b > 0\), let \(V_b = \{ \phi(t, x) : -b < t < b, x \in \text{In}(\mathcal{P}_g) \}\). For \(0 < c < 1\) and \(\varepsilon > 0\) sufficiently small, let \(\psi : \mathbb{R}^1 \to [0, 1]\) be of class \(C^k\), \(k \geq 2\), such that \(\psi = 1\) on \(V_c\) and \(\psi = 0\) outside \(V_{c/2}\). Let \(\mathcal{S}(A)\) be the saturation of \(A\) by the flow \(\phi\), given by \(\mathcal{S}(A) = \{ \phi(t, x) : t \in \mathbb{R}, x \in A \}\). Define the observable \(H\) by \(H(x) = \psi(x)\chi_{\mathcal{S}(A)}(x)\). For \(x \in U\) we have:

\[
\int_0^{a_k} H(\phi(t, x)) \, dt = \int_0^c H(\phi(t, x)) \, dt + \sum_{j=1}^{a_k} \int_{j-1}^{j+c} H(\phi(t, x)) \, dt + \int_{a_k}^{a_k+1} H(\phi(t, x)) \, dt + o(\varepsilon)
\]

\[
= c\chi_{\tilde{F}^0}(x) + 2c \sum_{j=1}^{a_k} \chi_{\tilde{F}^j}(x) + c\chi_{\tilde{F}^{a_k+1}}(x) + o(\varepsilon).
\]

Hence

\[
\frac{1}{a_k + 1} \int_0^{a_k+1} H(\phi(t, x)) \, dt = \frac{2c}{a_k + 1} \sum_{j=0}^{a_k} \chi_{\tilde{F}^j}(x) - \frac{c}{a_k + 1} \chi_{\tilde{F}^0}(x) + \frac{c}{a_k + 1} \chi_{\tilde{F}^{a_k+1}}(x)
\]

where

\[
\lim_{k \to +\infty} \frac{c}{a_k + 1} \chi_{\tilde{F}^0}(x) = 0 \quad \text{and} \quad \lim_{k \to +\infty} \frac{c}{a_k + 1} \chi_{\tilde{F}^{a_k+1}}(x) = 0.
\]

Therefore,

\[
\lim_{k \to +\infty} \frac{1}{a_k + 1} \int_0^{a_k+1} H(\phi(t, x)) \, dt = \lim_{k \to +\infty} \frac{2c}{a_k + 1} \sum_{j=0}^{a_k} \chi_{\tilde{F}^j}(x) + o(\varepsilon) = 2cL + o(\varepsilon)
\]

where the last equality follows from (6.14). Similarly,

\[
\lim_{k \to +\infty} \frac{1}{b_k + 1} \int_0^{b_k+1} H(\phi(t, x)) \, dt = 2c\tilde{L} + o(\varepsilon).
\]
Since $L = \hat{L}$, then for sufficiently small $\varepsilon$ and for all $x$ in the open set $S(U)$ we have:

$$\lim_{a_i \to +\infty} \frac{1}{a_i} \int_0^{a_i} H(\phi(t, x)) dt = \lim_{b_i \to +\infty} \frac{1}{b_i} \int_0^{b_i} H(\phi(t, x)) dt$$

It follows that for each $\lambda$ in $(\xi, \zeta)$ there are vector fields $g$ arbitrarily close to $f_0$ in the $C^2$-topology such that there is an open set of initial conditions for which the solution of $\dot{x} = g(x)$ has historic behaviour, as claimed.

In the proof of theorem 12, the conditions defining the set $C$ are only used to obtain theorem 11. Hence, for theorem 12, condition (P3) may be replaced in the definition of $C$ by the assumption that two successive nodes have different chirality, as remarked after the proof of theorem 11.

Heteroclinic tangencies also create new tangencies near them in phase space and for nearby parameter values. Based on [26, 33], it should be possible to obtain a topological interpretation of the asymptotic properties of these non-converging time averages and obtain a complete set of moduli for the attracting cycle.

7. An example

In this section we construct a family of vector fields in $\mathbb{R}^3$ satisfying properties (P1)–(P5). Thus, via theorem 12, we provide an explicit example where trajectories with historic behaviour have positive Lebesgue measure. Our example relies on Bowen’s example described in [33]. This is a vector field in the plane with structurally unstable connections. We use the techniques developed by Aguiar et al [2, 27] combined with symmetry breaking, to lift Bowen’s example to a vector field in $\mathbb{R}^3$ with periodic solutions having robust connections arising from transverse intersections of invariant manifolds.
7.1. The starting point

Consider the differential equation \((\dot{x}, \dot{y}) = g(x, y)\) given by
\[
\begin{align*}
\dot{x} &= -y \\
\dot{y} &= x - x^3
\end{align*}
\]
(7.15)
that is equivalent to the second order equation \(\ddot{x} = -x^3\). Its equilibria are \(O = (0, 0)\) and \(P^\pm = (\pm 1, 0)\). This is a conservative system, with first integral \(v(x, y) = \frac{\dot{x}^2}{2} \left(1 - \frac{x^4}{2}\right) + \frac{\dot{y}^2}{2}\).

From the graph of \(v\) (see figure 11(a)) it follows that the origin \(O\) is a centre and the equilibria \(P^\pm\) are saddles. The equilibria \(P^\pm\) are contained in the \(v\)-energy level \(v(x, y) = 1/4\) hence there are two one-dimensional connections, one from \(P^+\) to \(P^-\) and another from \(P^-\) to \(P^+\). Denote this cycle by \(\Gamma_1\). The region bounded by this cycle, that is filled by closed trajectories, will be called the invariant fundamental domain. For \((x, y) \neq (0, 0)\) inside the fundamental domain we have \(0 \leq v(x, y) < 1/4\) and the boundary of the fundamental domain intersects the \(x = 0\) axis at the points \((0, \pm \sqrt{2}/2)\).

7.2. An expression for Bowen’s example

For a given \(\varepsilon\), such that \(0 < \varepsilon \ll 1\), consider the following perturbation of (7.15):
\[
\begin{align*}
\dot{x} &= -y \\
\dot{y} &= x - x^3 - \varepsilon y \left(v(x, y) - \frac{1}{4}\right)
\end{align*}
\]
(7.16)

**Lemma 13.** In the flow of equation (7.16), the cycle \(\Gamma_1\) persists and is asymptotically stable with respect to the invariant fundamental domain.

**Proof.** The term \(-(v(x, y) - 1/4)\) is zero on \(\Gamma_1\) and positive in the interior of the fundamental domain. Therefore, the perturbing term \(-y(v(x, y) - 1/4)\) has the same sign as \(y\). Hence the heteroclinic connections \([P^+ \rightarrow P^-]\) and \([P^- \rightarrow P^+]\) are preserved and solutions starting away from the origin inside the fundamental domain approach the cycle when time goes to infinity as in figures 11(b) and (c).

7.3. Translating the cycle

For \(z^2 = y + 1\), Bowen’s example (7.16) takes the form
\[
\begin{align*}
\dot{x} &= 2z^2(1 - z^2) \\
\dot{z} &= z \left(x - x^3 - \varepsilon \left(\frac{x^2}{2} - \frac{x^4}{4} + \frac{(z^2 - 1)^2}{2} - \frac{1}{4}(z^2 - 1)\right)\right)
\end{align*}
\]
(7.17)

**Lemma 14.** The following assertions hold for equation (7.17):

(a) it is \(\mathbb{Z}_2\)-equivariant under the reflection on the \(z = 0\) axis;
(b) the \(z = 0\) axis is flow-invariant;
(c) the dynamics of (7.17) in the \(z > 0\) half-plane is orbitally equivalent to that of (7.16) in the \(y > -1\) half-plane.
Proof. Assertion (a) is a simple calculation, and it implies assertion (b). For (c), with \( z > 0 \), use 
\[
z^2 = y + 1 \quad \text{and} \quad \dot{z} = \frac{1}{2z} \text{ to put equation (7.16) in the form:}
\]

\[
\begin{aligned}
\dot{x} &= 1 - z^2 \\
\dot{z} &= \frac{1}{2z} \left( x - x^3 - \varepsilon \left( \frac{x^2}{2} - \frac{x^4}{4} + \frac{(z^2 - 1)^2}{2} - \frac{1}{4} \right) (z^2 - 1) \right).
\end{aligned}
\]

Multiplying both equations by the positive term \( 2z^2 \) does not affect the phase portrait and thus (7.16) with \( y > -1 \) is orbitally equivalent to (7.17) with \( z > 0 \).

74. The lifting

Now we are going to use a technique presented in [2, 21, 27] which consists essentially in three steps:

1. Start with a \( \gamma \)-equivariant vector field on \( \mathbb{R}^2 \) with a heteroclinic cycle where \( \dim \text{Fix}(\gamma) = 1 \), \( \gamma \in \mathbf{O}(2) \). The heteroclinic cycle involves two equilibria in \( \text{Fix}(\gamma) \) and one-dimensional heteroclinic connections that do not intersect the line \( \text{Fix}(\gamma) \).
2. Lift this to a vector field on \( \mathbb{R}^3 \) by rotating it around \( \text{Fix}(\gamma) \). This transforms one-dimensional heteroclinic connections into two-dimensional heteroclinic connections. The resulting vector field is \( \text{SO}(2) \)-equivariant under a 3-dimensional representation of \( \text{SO}(2) \). The attracting character of the cycle is preserved by the lifting.
3. Perturb the vector field to destroy the \( \text{SO}(2) \)-equivariance and so that the two-dimensional heteroclinic connections perturb to transverse connections.

Take \((x, z, \theta)\) to be cylindrical coordinates in \( \mathbb{R}^3 \) with radial component \( z \) and let \((x, z_1, z_2) = (x, z \cos \theta, z \sin \theta)\) be the corresponding Cartesian coordinates. Adding \( \dot{\theta} = 1 \) to (7.16) we obtain:

\[
\begin{aligned}
\dot{x} &= 2(1 - z_1^2 - z_2^2)(z_1^2 + z_2^2) \\
\dot{z}_1 &= z_1 \left[ x - x^3 - \varepsilon (z_1^2 + z_2^2 - 1) \left( \frac{x^2}{2} - \frac{x^4}{4} + \frac{(z_1^2 + z_2^2 - 1)}{2} - \frac{1}{4} \right) \right] - z_2 \\
\dot{z}_2 &= z_2 \left[ x - x^3 - \varepsilon (z_1^2 + z_2^2 - 1) \left( \frac{x^2}{2} - \frac{x^4}{4} + \frac{(z_1^2 + z_2^2 - 1)}{2} - \frac{1}{4} \right) \right] + z_1.
\end{aligned}
\]

Lemma 15. The flow of (7.18) for \( \varepsilon > 0 \) has a heteroclinic cycle \( \Gamma_0 \) that satisfies (P1)–(P3), consisting of two hyperbolic closed trajectories and two surfaces homeomorphic to cylinders. The cycle \( \Gamma_0 \) is asymptotically stable with respect to the lifting of the fundamental domain of (7.16).

Proof. We follow the arguments of [2, 27]. The periodic solutions are defined by:

\[ \mathcal{P}_1: \quad x = 1, \quad z_1^2 + z_2^2 = 1 \quad \text{and} \quad \mathcal{P}_2: \quad x = -1, \quad z_1^2 + z_2^2 = 1. \]

The connections are the lift of the one-dimensional connections, rotated around the fixed-point subspace of the symmetry. It follows that the heteroclinic connections are two-dimensional manifolds diffeomorphic to cylinders and a branch of the stable manifold of each periodic
solution coincides with a branch of the unstable manifold of the other. As remarked above, the stability of the cycle is preserved.

7.5. Time averages

Theorem 8 applied to (7.18) says that if \( \phi(t,X) \subset B(\Gamma_0) \) is a non-trivial solution of the differential equation, then the accumulation points of the time average \( \frac{1}{T} \int_0^T \phi(t,X)dt \) lie in the boundary of the segment joining the points

\[
A_1 = \left( \frac{e_2 - c_1}{e_2 + c_1}, 0, 0 \right) \quad \text{and} \quad A_2 = \left( \frac{e_1 - c_2}{e_1 + c_2}, 0, 0 \right).
\]

(7.19)

Since \( e_1 = c_1 = e_2 = c_2 = \sqrt{2} \), the points \( A_1 \) and \( A_2 \) coincide, although the centres of gravity of \( C_1 \) and \( C_2 \) do not. The polygon ensured by theorem 8 degenerates into a single point, the origin. This is in contrast to the example constructed in [27] where the polygon is degenerate because the centres of gravity of the nodes coincide. Usually, for initial conditions in the basin of attraction of heteroclinic cycles, the time averages do not converge as \( t \to +\infty \). However, if the vector field has symmetry, some non-generic properties appear. To destroy this degeneracy and obtain historic behaviour, it is enough to replace in (7.15) the first integral by:

\[
\bar{v}(x,y) = -(x-1)^2(x+1)^2 \left( 1 + \frac{x^2}{2} + x^2 \right) + \frac{y^2}{2}.
\]

(7.20)

For this case, the contracting and expanding eigenvalues at the two equilibria satisfy the conditions:

\[
\mu_1 = \frac{\sqrt{\sqrt{3}}}{\sqrt{5}} \quad \text{and} \quad \mu_2 = \frac{\sqrt{3}}{\sqrt{5}}
\]

and thus, for the lift of the corresponding system, \( A_1 = A_2 \). In particular, the Birkhoff time averages do not converge and thus they have historic behaviour. The next step, the second perturbation, will be performed for (7.18), constructed using the first integral \( \bar{v} \), but it could also be done starting with \( \bar{v} \).

7.6. The second perturbation

We perturb (7.17) by adding to the equation for \( \dot{z}_3 \) a term depending on \( \lambda \), as follows:

\[
\begin{align*}
\dot{x} &= 2(1 - z_1^2 - z_2^2)(z_1^2 + z_2^2) \\
\dot{z}_1 &= \varepsilon \left[ x - x^3 - \varepsilon (z_1^2 + z_2^2 - 1) \left( \frac{x^2}{2} - \frac{x^4}{4} + \frac{(z_1^2 + z_2^2 - 1)^2}{2} - \frac{1}{4} \right) \right] - z_2 + \lambda (x^2 - 1) \\
\dot{z}_2 &= \varepsilon \left[ x - x^3 - \varepsilon(z_1^2 + z_2^2 - 1) \left( \frac{x^2}{2} - \frac{x^4}{4} + \frac{(z_1^2 + z_2^2 - 1)^2}{2} - \frac{1}{4} \right) \right] + z_1.
\end{align*}
\]

(7.20)

A geometric argument is used to show that the invariant manifolds of the periodic solutions of (7.20) intersect transversely.
Lemma 16. For small $\lambda > 0$ and $\varepsilon > 0$, the flow of (7.20) has a heteroclinic cycle associated to two hyperbolic periodic solutions, $P_1$ and $P_2$, satisfying properties (P1)-(P5).

Proof. Properties (P1)-(P3) follow from the construction and from lemma 15. The perturbing term $\lambda(x^2 - 1)$ is zero on the planes $x = \pm 1$ that contain the cycles $C_1$ and $C_2$, so the periodic solutions persist. Since $\lambda(x^2 - 1)$ is positive for $-1 < x < 1$, then when $\lambda$ increases from zero, $W^u(P_a), a \in \mathbb{Z}_2$, moves towards larger values of $z_1$, while $W^s(P_{a+1})$ moves in the opposite direction. In particular, on the plane $x = 0$, for $\lambda \neq 0$, each pair of invariant manifolds meets transversely at two points (figure 12). Hence, there are two curves where each pair of invariant manifolds of the periodic solutions meets transversely and properties (P4) and (P5) hold.

Let $f^\lambda$ be the family of vector fields of (7.20). Theorem 11 says that for each $a \in \mathbb{Z}_2$ there is a sequence of values of $\lambda$ for which $W^u(P_a)$ is tangent to $W^s(P_{a+1})$, and that for other values of $\lambda$, there are closed trajectories with homoclinic tangencies, arbitrarily close to the connections. It follows that for these values of $\lambda$ the vector field $f^\lambda$ lies in the closure of a Newhouse domain. Theorem 12 ensures that there are sequences $0 < \xi_i < \zeta_i < \xi_{i+1}$, with $\lim \xi_i = 0$, such that for each $\lambda$ in $(\xi_i, \zeta_i)$ there are vector fields $g$ arbitrarily close to $f^\lambda$ in the $C^2$-topology such that there is an open set of initial conditions for which the solution of $\dot{x} = g(x)$ has historic behaviour.

Appendix A. $C^2$-Linearizing the hyperbolic periodic solution

For $a \in \{1, \ldots, k\}$, let $\Pi_a$ be a cross section transverse to the flow at $p_a \in P_a$. Since $P_a$ is hyperbolic, there is a neighbourhood of $p_a$ where the first return map to $p_a$, denoted by $\pi_a$, is $C^1$-conjugate to its linear part. Moreover:

**Lemma A.1.** Let $\pi_a$ be the first return map to $\Pi_a$. For each $r \geq 2$ there is an open and dense subset of $R^2$ such that, if the eigenvalues $(\lambda_a, \lambda_a)$ of $d\pi_a$ lie in this set, then there is a neighbourhood $V_a$ of $p_a$ in $P_a$ where $\pi_a$ is $C^r$-conjugate to its linear part.

**Proof.** Let $r \geq 2$. In order to ensure the existence of a $C^r$ conjugacy between $d\pi_a$ and the first return map to $\Pi_a$, we use the Takens’ criterion [32, sections 1 and 5] which asks for the Sternberg $\alpha$-condition. Following Takens’ terminology [32], let us define:

$$
\lambda = \lambda_c = e^{-\epsilon c} < 1, \quad \lambda = \lambda_c = e^{\epsilon c} > 1, \quad s = u = 1, h = 2
$$

and

$$
M = \lambda = m > 1, \quad N = \lambda^{-1} = n > 1.
$$

In order to apply the criterion, we should define the function $\beta(d\pi_a, k)$. The definition will depend on an auxiliary function $\beta(d\pi_a, k)$. This proof will be divided in three steps: characterisation of $\beta$, characterisation of $\alpha$ and application of the criterion.

1. The function $\beta$: The value of $\beta(d\pi_a, k)$ is that of the smallest $j \in N$ for which:

$$
\forall r < k, \quad N M^n r^{r-1} < 1.
$$

In other words, $\beta(d\pi_a, k)$ is the smallest $j \in N$ for which:

$$
\forall r < k, \quad \Phi(\lambda, \lambda, r) \lambda^j < 1, \quad \text{where} \quad \Phi(\lambda, \lambda, r) = \left(\frac{1}{\lambda_c}\right)^{1+r} \lambda^r.
$$

Thus $\beta$ depends on $d\pi_a$ through the latter’s eigenvalues. In particular, $\beta(d\pi_a, k) > 1 + r$ for $r < k$. Moreover, for $j - (r + 1) \in N$ large enough, the map $\Phi(\lambda, \lambda, r)$ increases with $r$. Therefore, it is sufficient to check condition (A.1) for $r = k$. Indeed, the value of $\beta(d\pi_a, k)$ is that of the smallest $j \in N$ for which:

$$
(\lambda^j \lambda^j < 1 \iff (\lambda^j \lambda^j < 1 \iff \lambda^j < 1.
$$

Define $j - (k + 1) = l$. Then it is easy to see that $\beta(d\pi_a, k)$ is the smallest $j \in N$ such that $\lambda^j \lambda^j < 1$. Taking logarithms, it follows that this is equivalent to:

$$
k \ln \lambda = l \ln \lambda < 0 \iff l > -k \frac{\ln \lambda}{\ln \lambda}.
$$

Since $l \in N$, its minimum value will be

$$
l = 1 + \left[-k \frac{\ln \lambda}{\ln \lambda}\right] \iff \beta(d\pi_a, k) = k + 2 + \left[-k \frac{\ln \lambda}{\ln \lambda}\right],
$$

where $[x]$ represents the largest integer less than or equal to $x \in R$. 

1904
2. The function $\alpha$: The value of $\alpha(d\pi_n, k)$ is that of the smallest $j \in N$ for which:

$$\forall r < \beta(d\pi_n, k), \quad \frac{M}{N} \text{N} \text{N} \text{N}^{-j} < 1.$$ 

In other words, $\alpha(d\pi_n, k)$ is the smallest $j \in N$ for which:

$$\forall r < \beta(d\pi_n, k), \quad \Phi(\lambda_r, \lambda, r) \lambda_r^{-j+1} < 1, \quad \text{with} \quad \Phi(\lambda_r, \lambda, r) = \left( \frac{1}{\lambda_r} \right)^{\lambda_r}.$$ 

Since $\Phi(\lambda_r, \lambda, r)$ increases with $r$, we would like to find the smallest $j \in N$ for which:

$$(\lambda_r^{-1})^{\beta(d\pi_n, k)} \lambda_r^{j+1} < 1.$$ 

If $j = \beta(d\pi_n, k) + 1 + l$, then:

$$(\lambda_r^{-1})^{\beta(d\pi_n, k)} \lambda_r^{(\beta(d\pi_n, k)+1)} < \lambda_r^{(\beta(d\pi_n, k)+1)} \lambda_r^l \iff \lambda_r^{-\beta(d\pi_n, k)} < \lambda_r^l$$

that happens if and only if $-\beta(d\pi_n, k) \ln(\lambda_r) < l \ln(\lambda_r)$. Therefore, $\alpha(d\pi_n, k) = \beta(d\pi_n, k) + 1 + l$ where $l$ is the smallest integer $l$ such that $-\beta(d\pi_n, k) \ln(\lambda_r) < l \ln(\lambda_r)$. Noting that $\ln(\lambda_r) < 0$ and $l \in N$, we have:

$$l > -\frac{\beta(d\pi_n, k) \ln \lambda_r}{\ln \lambda_e} \quad \text{with minimum value} \quad l = 1 + \left\lfloor -\frac{\beta(d\pi_n, k) \ln \lambda_r}{\ln \lambda_e} \right\rfloor.$$ 

In conclusion, since $\ln \lambda_r = -c_a$ and $\ln \lambda_e = e_a$, it follows that:

$$\beta(d\pi_n, k) = k + 2 \left\lfloor \frac{k e_a}{c_a} \right\rfloor$$

and

$$\alpha(d\pi_n, k) = \beta(d\pi_n, k) + 1 + l = k + 4 \left\lfloor \frac{k e_a}{c_a} \right\rfloor + \left( k + 2 + \left\lfloor \frac{k e_a}{c_a} \right\rfloor \right) \frac{e_a}{a}.$$ 

3. Applying the Sternberg condition: In order to have $C^\ast$ conjugacy between $\pi_n$ and its linear part, the eigenvalues of $d\pi_n$ must satisfy the $\alpha(d\pi_n, r)$-condition, that we proceed to explain in this context. For all $\nu_1, \nu_2 \geq 0$ such that $2 \leq \nu_1 + \nu_2 \leq \alpha(d\pi_n, r)$ we should have:

$$\lambda_e^{\nu_1-1} \lambda_e^{\nu_2} = 1, \quad \lambda_e^{\nu_1} \lambda_e^{\nu_2} = 1 \quad \text{and} \quad |\lambda_e^{\nu_1} \lambda_e^{\nu_2}| = 1$$

Indeed, $\lambda_e^{\nu_1} \lambda_e^{\nu_2} = e^{\nu_1 \mu_a e^{-\nu_2 \mu_a}} = 1$ if and only if $-\nu_1 \mu_a = \nu_2 \mu_a$. In summary, for all $\nu_1, \nu_2 \geq 0$ such that $2 \leq \nu_1 + \nu_2 \leq \alpha(d\pi_n, r)$, the following conditions should hold:

- $(\nu_1 - 1)c_a = \nu_2 e_a$
- $(\nu_2 - 1)c_a = (\nu_1 - 1)e_a$
- $\nu_1 \mu_a = \nu_2 \mu_a$. 

The set of smooth vector fields that satisfy the Sternberg $\alpha(d\pi_n, r)$-condition, for each $r \geq 2$, is open and dense in the set of vector fields satisfying (P1)–(P5). Hence, generically the assumptions are satisfied.
Appendix B. Control of flight times

B.1. Proof of lemma

1. If \( n = 0 \) (\( n \) corresponds to the number of loops around the cycle \( \Gamma_0 \)), it is trivial. For \( n \geq 1 \), we may write the following equality, omitting the dependence on \( X \):

\[
T_{a+nk} = T_0 + \tau_a + \tau_{a+1} + \cdots + \tau_{a+k-1} + \tau_{a+k} + \cdots + \tau_{a+2k-1} + \cdots + \tau_{a+(n-1)k} + \tau_{a+(n-1)k+1} + \cdots + \tau_{a+nk-1} + \tau_{a+nk}.
\]

Using corollary 3, the previous equality yields:

\[
T_{a+nk} = T_0 + \mu_a \tau_a - 1 + \mu_a \mu_{a+1} \tau_{a-1} + \cdots + \delta \left( \prod_{j=0}^{\ell-1} \mu_{a+j+1} \right) \tau_{a-1} + \cdots + \delta^\ell \left( \prod_{j=0}^{\ell-1} \mu_{a+j} \right) \tau_{a-1} = T_0 + \delta \left( \prod_{j=0}^{\ell-1} \mu_{a+j+1} + \cdots + \mu_{a+1} \right) \tau_{a-1} + \cdots + \delta^\ell \left( \prod_{j=0}^{\ell-1} \mu_{a+j} \right) \tau_{a-1}.
\]

2. This item follows from corollary 3. Indeed, we have:

\[
\tau_{a+nk}(X) = \mu_a \tau_{a+nk-1}(X) = \mu_a \mu_{a-1} \tau_{a+nk-2}(X) = \cdots = \delta^\ell \mu_a \tau_{a-1}(X).
\]

□

B.2. Proof of proposition

We divide the proof into two lemmas. First we show in lemma B.1, that it is sufficient to consider the limit when \( n \to \infty \) of the averages over one turn around \( \Gamma_0 \). Then in lemma B.2 we show that these averages tend to \( \Lambda_\omega \).

**Lemma B.1.** Let \( T_\ell, \ell \in \mathbb{N} \), be a sequence \( 0 = T_0 < T_1 < T_{\ell+1} \) with \( \lim_{\ell \to \infty} T_\ell = \infty \). Given \( h : \mathbb{R} \to \mathbb{R}^n \) an integrable map,

if \( \lim_{\ell \to \infty} \frac{1}{T_{\ell+1} - T_\ell} \int_{T_\ell}^{T_{\ell+1}} h(t) \mathrm{d}t = \omega \), then \( \lim_{\ell \to \infty} \frac{1}{T_\ell} \int_0^{T_\ell} h(t) \mathrm{d}t = \omega \).

**Proof.** First note that

\[
\frac{1}{T_\ell} \int_0^{T_\ell} h(t) \mathrm{d}t = \omega = \frac{1}{T_\ell} \int_0^{T_\ell} (h(t) - \omega) \mathrm{d}t = \sum_{j=1}^{\ell} \left( \frac{T_j - T_{j-1}}{T_\ell} \right) \int_{T_{j-1}}^{T_j} (h(t) - \omega) \mathrm{d}t.
\]

From the hypothesis, given \( \varepsilon > 0 \) there exists \( N_1 \) such that \( \ell > N_1 \) implies

\[
\frac{1}{T_\ell - T_{\ell-1}} \left| \int_{T_{\ell-1}}^{T_\ell} (h(t) - \omega) \mathrm{d}t \right| < \frac{\varepsilon}{2}.
\]
Let $A = \left| \int_0^{T_0} (h(t) - \omega)\, dt \right|$. Since $T_i \to \infty$ then there exists $N_2$ such that $T_{N_2} > 2A/\varepsilon$. Let $N_0 = \max\{N_1, N_2\}$. If $\ell > N_0$ then
\[
\frac{1}{T_i} \int_0^{T_i} (h(t) - \omega)\, dt \leq \frac{1}{T_i} \left| \int_0^{T_{N_1}} (h(t) - \omega)\, dt \right| + \frac{1}{T_i} \left| \int_{T_{N_1}}^{T_i} (h(t) - \omega)\, dt \right|
\leq A + \sum_{j=N_1}^{\ell} \frac{T_j - T_{j-1}}{T_i} \left| \int_{T_{j-1}}^{T_j} (h(t) - \omega)\, dt \right|
\leq \varepsilon + \frac{\ell}{2} \left( \frac{T_{N_2} - T_{N_1}}{T_i} \right) \leq \frac{\ell}{2} \left( 1 + \sum_{j=1}^{\ell} \frac{T_j - T_{j-1}}{T_i} \right) = \varepsilon.
\]

**Lemma B.2.** Let $f_0$ be a vector field in $\mathbb{R}^3$ satisfying (P1)–(P3). For each $a \in \mathbb{Z}_k$, and for each $\mu \in \mathbb{Z}_k$, the limit of the spatial average of $\phi(t,X)$ over one full turn around the heteroclinic cycle $\Gamma_0$ starting at $\text{In}(\mathcal{P}_a)$ is $A_{j}$. More precisely:

$$
\lim_{n \to \infty} \frac{1}{T_{a+(n+1)\mu}(X) - T_{a+n\mu}(X)} \int_{T_{a+(n+1)\mu}(X)}^{T_{a+n\mu}(X)} \phi(t,X)\, dt = A_{j}.
$$

**Proof.** First, recall that we are assuming that, for all $a \in \mathbb{Z}_k$, the jumps from $\text{Out}(\mathcal{P}_a)$ to $\text{In}(\mathcal{P}_{a+1})$ are instantaneous (see remark 1). Since $X \in \mathcal{B}(\Gamma_0)$, then for $t \in [T_a + nk, T_{a+1} + nk]$ with large $n$, the trajectory $\phi(t,X)$ gets very close to $\mathcal{P}_a$. Therefore, omitting the $(X)$ for shortness, we have:

$$
\lim_{n \to \infty} \frac{1}{T_{a+1+nk} - T_{a+nk}} \int_{T_{a+nk}}^{T_{a+1+nk}} \phi(t,X)\, dt = \lim_{n \to \infty} \frac{1}{T_{a+1+nk} - T_{a+nk}} \int_{T_{a+nk}}^{T_{a+1+nk}} \phi(t,X)\, dt = x_a.
$$

(B.1)

Without loss of generality, from now on we take $a = 1$. Then
\[
\frac{1}{T_{k+1+nk} - T_{1+nk}} \int_{T_{1+nk}}^{T_{k+1+nk}} \phi(t,X)\, dt
= \frac{1}{T_{k+1+nk} - T_{1+nk}} \left[ \int_{T_{1+nk}}^{T_{k+1+nk}} \phi(t,X)\, dt + \int_{T_{k+1+nk}}^{T_{2+1+nk}} \phi(t,X)\, dt + \cdots + \int_{T_{k+n+1+nk}}^{T_{k+1+nk}} \phi(t,X)\, dt \right]
= \sum_{b=1}^{k} \frac{1}{T_{b+1+nk} - T_{1+nk}} \int_{T_{b+1+nk} - T_{1+nk}}^{T_{b+1+nk}} \phi(t,X)\, dt.
\]

Recall that $T_{2+nk} - T_{1+nk} = T_{1+nk}$, and by corollary 3, for any $b \in \{2, \ldots, k\}$
\[
\frac{1}{T_{b+1+nk} - T_{1+nk}} = \frac{1}{T_{k+1+nk} - T_{1+nk}} = \frac{T_{b+nk}}{T_{b+1+nk} - T_{1+nk}} = \frac{T_{k+nk}}{T_{k+1+nk} - T_{1+nk}} = \ldots = \frac{T_{k+nk}}{T_{k+1+nk} - T_{1+nk}} = \frac{T_{k+nk}}{\text{den}(A_i)}.
\]
Therefore, the value of
\[
\lim_{n \to +\infty} \frac{1}{T_{k+1+nk} - T_{1+nk}} \int_{T_{1+nk}}^{T_{k+1+nk}} \phi(t, X) \, dt
\]
is, by (B.1),
\[
\lim_{n \to +\infty} \frac{1}{\text{den}(A)} \left[ \frac{1}{T_{2+nk} - T_{1+nk}} \int_{T_{1+nk}}^{T_{2+nk}} \phi(t, X) \, dt + \sum_{b=2}^{k} \frac{\mu_b \mu_{b-1} \cdots \mu_2}{T_{b+1+nk} - T_{b+nk}} \int_{T_{b+nk}}^{T_{b+1+nk}} \phi(t, X) \, dt \right]
\]
\[
= \frac{\mathfrak{X}_1 + \mu_2 \mathfrak{X}_2 + \cdots + \mu_k \mu_{k-1} \cdots \mu_2 \mathfrak{X}_k}{1 + \mu_2 + \cdots + \mu_k \mu_{k-1} \cdots \mu_2} = A_1.
\]

\[\square\]

B.3. Proof of lemma 6

Expanding \text{den}(A_a) and \text{den}(A_{a+1}), yields:
\[
\text{den}(A_a) = 1 + \mu_{a+1} + \mu_a \mu_{a+2} + \cdots + \prod_{l=1}^{k-1} \mu_{l+a}
\]
\[
\text{den}(A_{a+1}) = 1 + \mu_{a+2} + \mu_a \mu_{a+2} + \cdots + \prod_{l=1}^{k-1} \mu_{l+a+1}
\]
hence, since \(\prod_{l=0}^{k-1} \mu_{l+a+1} = \delta\),
\[
\mu_{a+1} \text{den}(A_{a+1}) = \mu_{a+1} + \mu_a \mu_{a+2} + \mu_a \mu_{a+2} + \cdots + \mu_a \mu_{a+2} + \mu_a \mu_{a+2} + \cdots + \prod_{l=1}^{k-1} \mu_{l+a+1}
\]
\[
= \mu_{a+1} + \mu_a \mu_{a+2} + \mu_a \mu_{a+2} + \cdots + \prod_{l=1}^{k-1} \mu_{l+a} + \delta
\]
\[
= \text{den}(A_a) - (1 - \delta).
\]

For \text{num}(A_a) and \text{num}(A_{a+1}) we obtain
\[
\text{num}(A_a) = \mathfrak{X}_a + \mu_{a+1} \mathfrak{X}_a + \mu_a \mu_{a+2} \mathfrak{X}_a + \cdots + \left( \prod_{l=1}^{k-1} \mu_{l+a} \right) \mathfrak{X}_a + k-1
\]
\[
\text{num}(A_{a+1}) = \mathfrak{X}_{a+1} + \mu_{a+2} \mathfrak{X}_{a+2} + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \cdots + \left( \prod_{l=1}^{k-1} \mu_{l+a+1} \right) \mathfrak{X}_{a+k}
\]
and, since \(\mathfrak{X}_{a+k} = \mathfrak{X}_a\), we get
\[
\mu_{a+1} \text{num}(A_{a+1}) = \mu_{a+1} \mathfrak{X}_{a+1} + \mu_{a+1} \mu_{a+2} \mathfrak{X}_{a+2} + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \cdots + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \cdots + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \cdots + \left( \prod_{l=1}^{k-1} \mu_{l+a+1} \right) \mathfrak{X}_{a+k}
\]
\[
= \mu_{a+1} \mathfrak{X}_{a+1} + \mu_{a+1} \mu_{a+2} \mathfrak{X}_{a+2} + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \cdots + \mu_a \mu_{a+2} \mathfrak{X}_{a+2} + \cdots + \left( \prod_{l=1}^{k-1} \mu_{l+a} \right) \mathfrak{X}_{a+k-1} + \delta \mathfrak{X}_a
\]
\[
= \text{num}(A_a) - (1 - \delta) \mathfrak{X}_a
\]
and the lemma is proved. \[\square\]
