Research article

Keywords: Abomasum, Antioxidant parameters, Gastrointestinal nematode parasite, Histopathological changes, Local immune response, Sheep
Abstract

Background: *Haemonchus contortus* is a blood-feeding gastrointestinal nematode (GIN) that parasitizes in the abomasum of ruminants. Infections caused by this nematode possess a serious threat to livestock production worldwide. The influence of medicinal plants using for control of haemonchosis on the local immune response of abomasal mucosae in GIN-infected sheep, however, has not been reported. This study evaluated the effect of *Artemisia absinthium* and *Malva sylvestris* as dietary supplements containing bioactive compounds on antioxidant response and histopathological changes in the abomasa of the lambs. Twenty-four lambs were divided into four groups: unsupplemented lambs (UNS), lambs supplemented with *A. absinthium* (ART), lambs supplemented with *M. sylvestris* (MAL), and lambs supplemented with both plants (ARTMAL). All lambs were infected orally with approximately 5000 L3 larvae of *H. contortus*. The experiment was conducted for 75 d, all animals were then slaughtered, and the abomasal tissues were examined for antioxidant parameters and histopathology.

Results: Methanolic extracts of wormwood and mallow were separated into four fractions by semi-preparative high-performance liquid chromatography, which identified saccharides, phenols, phenolic acids, flavonoids, polyphenols, esters, fatty acids, lipids, and other substances. The concentration of malondialdehyde in the abomasal mucosa was lower in ARTMAL (*P* < 0.05), and the total antioxidant capacity was higher in MAL (*P* < 0.05), than in UNS. Serum antioxidant parameters were not affected by the treatments (*P* > 0.05). Histopathological changes were mainly detected in the mucosal membrane of the abomasum, with the presence of infiltrates of inflammatory cells in MAL, ART, and ARTMAL. Increase mucus production was observed in the ARTMAL. The number of mast cells was significantly higher in UNS and ART than MAL (*P* < 0.01 and *P* < 0.05). Plasma cell numbers were higher in ARTMAL than MAL (*P* < 0.05). Abomasal tissue regenerated more frequently in ARTMAL than the other experimental groups.

Conclusions: These results represent the first report of the impact of *A. absinthium* and *M. sylvestris* on antioxidant parameters and local immune responses of abomasal mucosa of lambs infected with a GIN parasite. Wormwood and mallow applied as dietary supplements may increase the resistance of lambs to GIN infections.

Background

Gastrointestinal nematodes (GINs) represent a major threat to the small-ruminant industry worldwide. *Haemonchus contortus* is one of the most pathogenic GINs, mainly because of its blood-feeding behaviour. Infections with this parasite are associated with negative impacts on animal health, welfare, and production, which can lead to increased mortality, predominantly in young animals (1). The control of GIN infections is usually limited to the frequent and repeated use of anthelmintic drugs. Their excessive use, however, has led to the development of anthelmintic resistance in GIN populations (2) and has increased the level of chemical residues in animal products (3). The expansion of anthelmintic resistance and consumer demand for chemically free animal products have created an urgent need for a more
sustainable alternative control of GINs (4, 5), such as nutritional supplementation with medicinal plants (6–8).

Medicinal plants contain various bioactive compounds, such as alkaloids, flavonoids, terpenoids, lactones, and glycosides, that have different modes of therapeutic action, e.g. immunomodulatory, anti-inflammatory, antioxidant, or anthelmintic (9–12). Some secondary metabolites of plants have direct anthelmintic activity against GINs (13–15). Our previous studies, however, concluded that supplementation with a mixture of dried medicinal plants in the diet of lambs could slow the dynamics of infection and increase the resistance of lambs to parasitic infection (16–18).

The supplementation of diets with plant nutraceuticals containing bioactive substances has received increasing attention for manipulating host nutrition and indirectly improving animal resistance to GIN infections (19–21). Nutraceuticals can provide enough nutrients essential for tissue maintenance and blood homeostasis, but also for host immune responses against parasites (7), which can affect the overall health of animals. Immunity to nematodes is associated with innate and acquired responses, but the local cellular immune responses in host abomasa are considered the most important defences against haemonchosis. Mucosal mast-cell hyperplasia, the formation of globular leukocytes, eosinophilia (an increase in eosinophils in blood and tissue), increased mucus production in the abomasum, and the production of specific antibodies typically emerge during infection (22–24). The presence of nematodes in the abomasum can also induce the production of reactive oxygen species by immune cells, which can damage the parasites and cause oxidative stress in the host (25). Plant secondary metabolites may improve the health of animals through their antioxidant and immune-enhancing properties (26, 27). The mechanisms of sheep resistance to GINs via plant secondary metabolites, however, are not fully understood.

Many studies have investigated alterations in sheep abomasa in association with H. contortus infection (28–30). To our knowledge, the influence of medicinal plants on antioxidant parameters and histopathological changes in sheep abomasa have not been reported. We hypothesised that dietary supplementation with medicinal plants would influence the local immune response in the abomasum and positively affect the antioxidant status of infected animals. This study aimed to evaluate the effect of diets containing medicinal wormwood and mallow (1) on antioxidant parameters in sera and abomasal mucosa, and (2) on histopathological changes in the abomasal tissues of lambs experimentally infected with H. contortus.

Results

Plant methanolic extracts

The methanolic extracts of wormwood, Artemisia absinthium, and mallow, Malva sylvestris, were each divided into four fractions (Table 1). The fractions of the A. absinthium methanolic extract contained the highest concentrations of very polar substances, saccharides, peptides, and polar phenolic acids (46
000 µg/mL), followed by polyphenols, less polar phenolic acids, and sesquiterpenes (20 000 µg/mL). Nonpolar substances, lipids, resins, and di- and triterpenes had concentrations of 12 000 µg/mL, and low-polarity polyphenols, phenolic acids, and sesquiterpenes had concentrations of 6000 µg/mL. The fractions of the *M. sylvestris* methanolic extract contained 150 000 µg/mL saccharides and polar phenols, 42 000 µg/mL anthocyanins and other phenolic compounds, 18 000 µg/mL nonpolar substances, esters, fatty acids, and lipids, and 9000 µg/mL polyphenols, flavonoids, and phenolic acids.

### Table 1

Composition and concentration of the fractions of plant methanolic extracts.

| Fraction (F) | RT (min) | Composition of fraction | FW (mg/g) | Concentration (µg/mL) |
|--------------|----------|-------------------------|-----------|-----------------------|
| *A. absinthium* |          |                         |           |                       |
| F1           | 1.00–5.25| Very polar substances, sugars, polar peptides and proteins, polar phenolic acids | 45.913 | 46 000 |
| F2           | 5.25–18.00| Polyphenols, less polar phenolic acids, sesquiterpenes | 19.813 | 20 000 |
| F3           | 18.00–25.00| A similar spectrum of substances as F2, but of lower polarity | 5.583 | 6000 |
| F4           | 25.00–45.00| Nonpolar substances, lipids, resins, di- and triterpenes | 12.102 | 12 000 |
| *M. sylvestris* |          |                         |           |                       |
| F1           | 1.00–5.25| Sugars, polar phenols | 150.441 | 150 000 |
| F2           | 5.25–10.50| Anthocyanins, other phenolic compounds | 41.818 | 42 000 |
| F3           | 10.50–17.60| Polyphenols, flavonoids, phenolic acids | 9.403 | 9000 |
| F4           | 17.60–45.00| Nonpolar substances, esters, fatty acids, lipids | 18.368 | 18 000 |

*RT*, retention time of collection; *FW*, fresh weight

### Antioxidant Parameters

The folds of the abomasa were flushed with saline, and the mucosae were subsequently sampled by scraping the inside surfaces with a glass slide and stored at -80 °C until analysis. Tissue processing and antioxidant assays have been previously described in more detail (51). The activity of glutathione peroxidase (GPx) in the serum and abomasal mucosa was determined spectrophotometrically as described by (52). One unit of enzymatic activity was equal to 1 µmol of NADPH oxidised per minute at 340 nm and is expressed per gramme of tissue protein or millilitre of serum. The total antioxidant
capacity (TAC) of the serum and abomasal mucosa was determined using a ferric reducing antioxidant power assay following the method of (53). The final results are expressed in mmol Fe$^{2+}$/L of serum or µmol Fe$^{2+}$/g of tissue protein. The malondialdehyde (MDA) concentration in the serum and tissue homogenate was measured using a modified fluorometric method as described by (54). Protein concentrations in the tissues were determined spectrophotometrically as described by (55).

**Abomasum Histology**

Each abomasum was removed after necropsy, opened along the greater curvature, and gently washed with water to recover nematodes. Two tissue samples from fundic part of the abomasum (approximately 3 × 3 cm) were removed and routinely fixed in 10% neutral buffered formalin, embedded in paraffin (Paraplast, Sigma-Aldrich, Steinheim, Germany), and subsequently cut with a rotatory microtome into sections 4 µm thick. The paraffin slides were automatically stained with haematoxylin and eosin (Varistain Gemini Thermo Scientific, Leicestershire, UK) for histopathological examination and counting eosinophils, plasma cells, and mitotic figures (to determine mitotic activity of the epithelial cells at the neck of glands). Mucus was stained with Periodic acid-Shiff stain, and mast cells were stained with toluidine blue. Eosinophils, plasma cells, mast cells, and mitotic figures in the epithelial cells of the glands in abomasal mucous membrane were counted for each animal in 10 randomly selected fields at an objective magnification of 400 × using an Olympus BX43 light microscope equipped with an SC30 digital camera (Olympus Optical, Tokyo, Japan). Photomicrographs were recorded and analysed using CellSens Entry 2011 (Olympus Lifescience, Tokyo, Japan).

**Immune Cells In The Abomasal Mucosa**

Figure 2 shows the mean numbers of eosinophils (A), mast cells (B), plasma cells (C), and mitotic figures (D) on day 75 in the abomasal mucosae of the lambs in all experimental groups. The number of eosinophils in the abomasal mucosa did not differ significantly between the groups (Fig. 2A). The number of mast cells was significantly higher in UNS and ART ($P<0.01$ and 0.05, respectively) than MAL (Fig. 2B). The mean number of plasma cells was significantly higher ($P<0.05$) in ARTMAL than MAL (Fig. 2C). The number of mitotic figures (mitotic activity of the epithelial cells at the neck of glands; Fig. 1F) was significantly higher in ARTMAL than MAL ($P<0.05$) and UNS and ART ($P<0.001$). Mitosis was more frequent in MAL ($P<0.05$) than UNS and ART (Fig. 2D).

**Discussion**

This experiment was part of a study investigating the anthelmintic activity of *A. absinthium* and *M. sylvestris* against *H. contortus* in lambs (31). The present part of the study investigated the indirect increase in resistance of lambs infected with *H. contortus* by supplementing their diets with *A. absinthium* and *M. sylvestris*. The fractionation of the methanolic extracts indicated that *M. sylvestris*
contained more saccharides, polar phenols, and a higher concentration of flavonoids than did *A. absinthium*. *M. sylvestris* flowers are rich in bioactive compounds, such as phenols, flavonoids, and carotenoids, which are characterised by their powerful antioxidant properties (32). In contrast, *A. absinthium* stems contained proteins, sesquiterpenes, di- and triterpenes, and resins but lower concentrations of phenolic acids and polyphenols. *A. absinthium*, however, also contains many phytochemical compounds such as lactones, terpenoids, essential oils, resins, tannins, and phenols that have antioxidant, antimicrobial, anthelmintic, and immunomodulatory activity (33).

The presence of nematodes in sheep abomasum is usually associated with the production of reactive oxygen species by immune cells, which can represent host defensive mechanisms against parasites but can also generate oxidative stress (34). Oxidative stress arises as an imbalance between the formation of oxidants and antioxidants in the body and can damage lipids, DNA, proteins, and carbohydrates, which eventually lead to tissue damage and inflammation (25). Traditional medicinal plants have long been known for their antioxidant properties. Amongst all secondary metabolites in plants, phenolic compounds, which are present in both *A. absinthium* and *M. sylvestris* (31), are considered to be the strongest natural antioxidants (35). The analysis of the antioxidant parameters indicated that dietary supplementation with two medicinal plants in ARTMAL reduced the MDA level in the abomasum of infected sheep by day 75, which could indicate the inhibition of lipid peroxidation and the reduction of oxidative stress in abomasal tissue. MDA levels tend to increase during parasitic infection, due to cellular injury in tissues and are an indicator of oxidative stress (36). The antioxidant activity of *A. absinthium* has been previously reported (33) and has been attributed to an abundant phenolic content. Bora and Sharma (37) reported that *A. absinthium* had strong antioxidant properties and could be used to prevent oxidative stress during disease by reducing lipid peroxidation. *M. sylvestris* also has strong antioxidant properties represented by the reduction of reactive oxygen species and inhibition of lipid peroxidation (32). MDA levels in our study were significantly lower only in ARTMAL compared to UNS, so the combination of these two herbs may be necessary to reduce oxidative stress. Interestingly, TAC in the abomasum was significantly higher only in MAL. This parameter represents all antioxidants present in tissue or plasma and provides an integrated parameter of the status of antioxidants. Our results indicated that supplementing diets with these medicinal plants could reduce oxidative stress and affect the antioxidant status of lambs infected with *H. contortus*. The parameters of serum antioxidants, however, were not affected by the treatments, so we suggest that these two medicinal plants only affect antioxidant parameters locally.

Protective immune responses against *H. contortus* are associated with the infiltration of inflammatory cells, such as lymphocytes, macrophages, eosinophils, mast cells, and plasma cells, into the abomasal mucosa (24). Our study found similar infiltrations with immune cells in all groups, with the highest intensity in ARTMAL and lowest in UNS. Paolini *et al.* (38) also observed a higher number of inflammatory cells in the fundic part of the abomasum of goats infected with *H. contortus* that received tannins representing 5% of the dietary dry matter compared to a control group. The inflammatory infiltrates in our experiment were mainly localised in both the superficial and basal portions of the mucosa in all treated groups but only in the basal portions of the abomasal glands in UNS. Pérez *et al.*
(39) found infiltrates of eosinophils and mononuclear cells mostly in the deep areas of the mucosa in goats infected with *H. contortus*, with fewer infiltrates in the submucosa. The expansion of immune cells to all layers of the mucosa in our study was probably affected by the stronger inflammation in these groups or by the immunomodulatory effect of the plant supplements. Five of the six animals in MAL were characterised by the presence of lymphoid nodules in the mucosa. Gossner *et al.* (40) frequently detected these lymphoid aggregates in susceptible lambs infected with the abomasal nematode *Teladorsagia circumcincta*. Salman and Duncan (41) also observed lymphoid aggregates at the base of the mucosa in sheep vaccinated against *H. contortus*, which was due to repeated immunisation and an improved immune response. In the present study the nutrient supplementation with plants and their bioactive compounds probably affected local immune response in the abomasum.

The gastrointestinal tract is covered with a protective layer of mucus containing mainly mucins and other substances such as immunoglobulins, which can inhibit the growth of parasites or eliminate them from the tissue. This mucosal layer represents the first line of innate defence against GIN infections (42). Increased secretion of mucus and the occurrence of inhibitory substances in the mucus have been associated with the development of immunity against GINs (43). Pérez *et al.* (39) described an increase in mucus secretion in the abomasum together with the infiltration of immune cells into the abomasal mucosa of goats infected with *H. contortus*. Mucus in our experiment was produced most strongly throughout the thickness of the mucosa in ARTMAL, perhaps due to the bioactive compounds of the plants and the strongest intensity of inflammation in this group. ARTMAL also had the lowest worm count in the abomasa (31), which could have been caused by the elimination of parasites by the mucus.

The infiltration of abomasal tissue by eosinophils, mast cells, and other immune cells is a natural response to *H. contortus* infection in small ruminants. Eosinophilia is often associated with resistance (44) because eosinophils play an essential role in the host response against GINs by killing the parasites. The number of tissue eosinophils did not differ significantly between the experimental groups, perhaps because medicinal plants do not affect counts of tissue eosinophils. Paolini *et al.* (38) reported similar results, where dietary supplementation with condensed tannins did not affect the numbers of eosinophils in the abomasa of goats infected with *H. contortus*. The lack of significant differences between the experimental groups may also have been due to an inappropriately timed necropsy. Terefe *et al.* (45) reported no significant differences in the number of tissue eosinophils between susceptible and resistant breeds of lambs infected with *H. contortus*. They also suggested an inappropriate timing of necropsy, which was supported by the results of a haematological examination, where blood eosinophilia peaked between 10 and 20 d after infection. We did not analyse blood parameters, so we could not confirm this finding. Our previous studies, however, did not identify any changes in counts of blood eosinophils in groups treated with a mixture of medicinal plants (16, 17), so we did not expect medicinal plants to positively affect counts of blood and tissue eosinophils.

Mast cells are involved in a variety of physiological functions, including parasite elimination (46). Their expansion and distribution in tissues can change in response to helminth parasites (47). The numbers of mucosal mast cells in our experiment were higher in ART and ARTMAL than MAL. Medicinal plants are a
source of bioactive compounds, which can influence the natural immunity of an animal. For example, Tzamaloukas et al. (48) found that the local immune response against T. circumcincta improved in lambs that grazed on chicory and sulla. These lambs had higher numbers of mast cells and globular leucocytes in abomasal mucosa and a poorer development of nematodes. In our study, the lowest number of mast cells in the group treated with M. sylvestris may have been due to the anti-inflammatory properties of the bioactive compounds in this plant (32). These anti-inflammatory properties may help to account for the higher number of mast cells in UNS than MAL. H. contortus infections are associated with an increase in plasma cells in abomasal tissue (49), and the presence of these cells has been linked to the production of nematode-specific antibodies, which play a role in protective immune responses (24). MAL in our experiment had fewer plasma cells than did ARTMAL. Again, the anti-inflammatory effect of the M. sylvestris bioactive compounds may have affected the reduction of plasma cells in the abomasal tissue. Interestingly, the levels of IgG and IgA in the serum did not differ significantly between MAL and ARTMAL (31), but we assume that the difference in antibody production could be local, in the abomasal mucus. Analysing local antibody responses may thus be interesting.

Abomasal mucosa is often damaged during H. contortus infections, which can be due to the presence of the parasite or of reactive oxygen species, which arise during these infections. Tissues can regenerate under improved health conditions, indicated by an increase in mitotic figures in infected tissue. The number of mitotic figures in the abomasal mucosa in our experiment was higher in both MAL and ARTMAL than UNS and ART. Both A. absinthium and M. sylvestris have strong antioxidant properties, and they may protect abomasal mucosa and promote mucosal healing by the elimination of free radicals. The thicker mucus in ARTMAL may also have reduced mucosal damage caused by reactive oxygen species because mucus can also act as an antioxidant (50). M. sylvestris alone or in combination with A. absinthium may therefore enhance the regeneration of damaged tissue by their antioxidant properties. Dietary supplementation with these two medicinal plants may consequently influence the local immune response in the abomasum and affect the local status of antioxidants of an infected animal, but more research is needed.

**Conclusion**

This study represents the first report of the effects of medicinal plants (A. absinthium and M. sylvestris) on antioxidant parameters and local immune responses of abomasal mucosa of lambs infected with parasitic GINs. Treatment with the medicinal plants influenced antioxidant parameters in the abomasal mucosa and helped trigger a local immune response in tissues. We can conclude that dietary supplementation with medicinal plants may increase the resistance of lambs to infection with H. contortus. Further research, however, is needed to understand these effects of medicinal plants.

**Methods**

**Animals and experimental design**
All procedures and animal care followed European Community guidelines (EU Directive 2010/63/EU). The experimental protocol was approved by the Ethical Committee of the Institute of Parasitology of the Slovak Academy of Sciences, following national legislation in Slovakia. Permission to collect samples and to carry out the experiment was granted by the participating sheep farmers. The experiment was part of a larger study that evaluated the effect of dry Artemisia absinthium and Malva sylvestris plants on the parasitic gastrointestinal nematode H. contortus in lambs, which has previously been described in more detail (31). Briefly, twenty-four 3–4 month-old female lambs (Improved Valachian) with initial body weights of 18.67 ± 0.55 kg were housed in common stalls on a commercial sheep farm (Hodkovce, Slovakia) and maintained in their production system during the experiment with free access to water. After a period of adaptation, all parasite-free lambs were infected orally with approximately 5000 third-stage (L3) larvae of a strain of H. contortus (MHCo1) susceptible to anthelmintics (17). Each animal was fed oats (500 g dry matter (DM)/d) and meadow hay (ad libitum). Infected lambs were randomly divided into four groups of six animals each (six lambs/group, one stall/group) based on their live weights: unsupplemented lambs (UNS), lambs supplemented with dried A. absinthium stems (ART, 1 g DM/d/lamb), lambs supplemented with dried M. sylvestris flowers (MAL, 15 g DM/d/lamb), and lambs supplemented with a mixture of dried A. absinthium stems and M. sylvestris flowers (ARTMAL, 16 g DM/d/lamb). The number of animals used in the experiment was assigned following VICH GL13 guidelines proposed by European Medicines Agency. The dried plant components of A. absinthium and M. sylvestris both from commercial sources (AGROKARPATY, Plavnica, Slovak Republic) were mixed daily with the oats during the experimental period (75 d). Qualitative phytochemical screening of active compounds in aqueous plant extracts (see below) identified mainly tannins and saponins (A. absinthium) and tannins, flavonoids, glycosides, alkaloids, and terpenoids (M. sylvestris) (31). The phytochemical substances of A. absinthium contained 6.48 g/kg DM phenolic acids and 0.35 g/kg DM flavonoids, M. sylvestris contained 0.65 g/kg DM phenolic acids and 6.48 g/kg DM flavonoids, and the mixture of both plants contained 10.7 g/kg DM phenolic acids and 5.51 g/kg DM flavonoids (31). The serum samples (on day 75 of infection) were obtained by centrifuging blood samples at 1200 g for 10 min at room temperature and were stored at -70 °C until analysis. All animals were euthanised by using of pentobarbital overdose (Dolethal, Vetoquinol, UK, Ltd.) on 75 d after infection, (abattoir of the Centre of Biosciences of SAS, Institute of Animal Physiology, Košice, Slovakia, No. SK U 06018), and helminthological dissections were performed (17). The carcasses were sent at the Department of Pathological Anatomy and Pathological Physiology, University of Veterinary Medicine and Pharmacy in Košice in the Slovak Republic. Mean worm abomasal counts were 899 ± 95, 984 ± 382, 876 ± 269 and 787 ± 335 for UNS, ART, MAL and ARTMAL, respectively (31). Moreover, samples of their abomasa were collected for the evaluation of antioxidant parameters and histopathological examination.

Plant Methanolic Extracts

We separately dissolved 0.248 g of A. absinthium and 0.262 g of M. sylvestris in 1 mL of methanol (MeOH) to final concentrations of 250 mg/mL and then centrifuged the extracts for separating the insoluble fractions. The supernatants were used for further fractionation. Some fractions were prepared
using a Dionex Ultimate 3000 semi-preparative high-performance liquid chromatograph (HPLC) with a binary HPLC pump, autosampler, PDA detector, fraction collector (AFC-3000), column-temperature controller, and mobile-phase degasser (Thermo Scientific, Sunnyvale, CA, USA). The fractions were separated on a C18 column (15 µm, 280 × 10 mm (Phenomenex, Torrance, CA, USA), tempered at 26 °C with mobile phases of water (A) and MeOH (B) by gradient elution. The initial gradient was 5% phase B (from 0 to 5 min), increasing to 100% B in 40 min, which was maintained for 5 min and was followed by 10 min of equilibration at an initial level of 5% B from 47 to 57 min. The flow of the mobile phase was 9 mL/min. An injection volume of the methanolic extract was 100 µL. The separation was measured as an absorption intensity of spectra monitored within a range of 190–400 nm. The analytical outputs were acquired and processed using Chromeleon 7.2.8 (Thermo Scientific Dionex, Sunnyvale, CA, USA). Some fractions were evaporated to dryness using a vacuum rotary evaporator (Büchi rotavapor 100, Flawil, Switzerland) at 40 °C, redissolved in 1 mL of 100% MeOH, moved to 2-mL vials, and again evaporated to dryness in a stream of nitrogen at 35 °C. The evaporating flask was then washed three times with 1.5 mL of MeOH, and combined volumes were added to the previous fraction and evaporated using nitrogen. Dry samples were stored at -18 °C. The compositions and concentrations of the fractions of the methanolic extracts are presented in Table 1.

### Calculations And Statistical Analysis

Data for the antioxidant parameters and immune cells in the abomasal mucosa were evaluated by multiple comparisons using one-way ANOVAs. Differences between the groups in both analyses were evaluated using Bonferroni post hoc tests. Student’s t-tests were applied to assess the differences between the mean numbers of immune cells for the groups on day 75. The significance level was set at $P < 0.05$.

### Abbreviations

ART, lambs supplemented with *A. absinthium* stems; ARTMAL, lambs supplemented with a mixture of *A. absinthium* stems and *M. sylvestris* flowers; DM, dry matter; F, fraction; FW, fresh weight; GIN, gastrointestinal nematode; GPx, glutathione peroxidase; HE, haematoxylin and eosin staining; HPLC, high-performance liquid chromatography; MAL, lambs supplemented with *M. sylvestris* flowers; MDA, malondialdehyde; MeOH, methanol; MHCo1, *H. contortus* strain susceptible to anthelmintics; NS, not significant; PAS, Periodic acid-Shiff staining; RT, retention time of collection; TAC, total antioxidant capacity; UNS, unsupplemented lambs.

### Declarations

**Ethics approval and consent to participate:**

All procedures and animal care followed European Community guidelines (EU Directive 2010/63/EU). The experimental protocol was approved by the Ethical Committee of the Institute of Parasitology of the
Slovak Academy of Sciences, following national legislation in Slovakia. Permission to collect study samples was granted by the participating sheep farmers. The owners of the animals gave verbal consent to carry out the experiment.

Consent for publication

Not applicable.

Availability of data and materials

The datasets used and/or analysed during the current study are available from the corresponding author on reasonable request.

Competing interest

The authors declare that they have no competing interests.

Funding

This study was supported by funds from the Slovak Research and Development Agency (APVV 18-0131) and the STSM Grant from the COST Action CA16230 www.combar-ca.eu. The role of the APVV project and STSM Grant of COST project allowed cooperation of researchers and Ph.D. students from the Institute of Animal Physiology of CBv of SAS, Parasitological Institute of SAS, Warsaw University of Life Sciences in Poland, and Czech University of Life Sciences in Prague to address the challenges related to the treatment of parasite infection. The funder had no role in study design, data collection, and analysis, decision to publish, or preparation of the manuscript.

Authors’ contributions

DM performed the laboratory and statistical analyses, interpreted the results, and wrote the manuscript. MSF performed the histopathological analyses and prepared the photographs of the histopathological sections. ZV was responsible for the design of the study, the conception and coordination of the experiment, and reviewed the manuscript. KK performed the antioxidant analyses. KC reviewed the dossier for the ethical application and critically revised the manuscript. PM and JT analysed the fractions of plant methanolic extracts. JV, MM and JK reviewed the manuscript. MV supervised the research, reviewed the manuscript, and added final corrections. All authors read and approved the final manuscript.

Acknowledgements

The authors are grateful to Valéria Venglovská, Peter Jerga and Gabriel Benkovský for laboratory and technical assistance. This article is based upon work from COST Action COMBAR CA16230, supported by COST (European Cooperation in Science and Technology).
