Abstract: Let $G$ be a graph, for any real $0 \leq \alpha \leq 1$, Nikiforov defines the matrix $A_\alpha (G)$ as $A_\alpha (G) = \alpha D(G) + (1 - \alpha) A(G)$, where $A(G)$ and $D(G)$ are the adjacency matrix and diagonal matrix of degrees of the vertices of $G$. This paper presents some extremal results about the spectral radius $\rho_\alpha (G)$ of the matrix $A_\alpha (G)$. In particular, we give a lower bound on the spectral radius $\rho_\alpha (G)$ in terms of order and independence number. In addition, we obtain an upper bound for the spectral radius $\rho_\alpha (G)$ in terms of order and minimal degree. Furthermore, for $n > l > 0$ and $1 \leq p \leq \left\lfloor \frac{n-1}{2} \right\rfloor$, let $G_p \equiv K_l \cup (K_p \cup K_{n-p-l})$ be the graph obtained from the graphs $K_l$ and $K_p \cup K_{n-p-l}$ and edges connecting each vertex of $K_l$ with every vertex of $K_p \cup K_{n-p-l}$. We prove that $\rho_\alpha (G_{p+1}) < \rho_\alpha (G_p)$ for $1 \leq p \leq \left\lfloor \frac{n-1}{2} \right\rfloor - 1$.

Keywords: spectral radius; minimal degree; independence number; $\alpha$-adjacency matrix

1. Introduction

Let $G = (V(G), E(G))$ be a simple and undirected connected graph with vertex set $V(G) = \{v_1, v_2, \ldots, v_n\}$ and edge set $E(G) = \{e_1, e_2, \ldots, e_m\}$. To simplify the notation, we represent a vertex just by $u$ and then an edge is just represented by $uv$, we say that $u$ is adjacent to $v$, or that $u$ and $v$ are neighbors and we write $u \sim v$. The adjacency matrix of $G$, denoted by $A(G) = (a_{ij})$ is a symmetric matrix of order $n$ such that $a_{ij} = 1$ if $v_i$ and $v_j$ are adjacent, and 0 otherwise. Let $d_i = d_{G}(v_i)$ be the degree of vertex $v_i$ in $G$. The largest and smallest vertex degrees of $G$ are denoted by $\Delta(G)$ and $\delta(G)$, respectively. The degree matrix of $G$, denoted by $D(G)$, is the diagonal matrix with diagonal entries the vertex degrees of $G$. A $k$-regular graph is a graph where every vertex has degree $k$. The complement of a graph $G$ is represented by $\overline{G}$. The spectrum of a matrix $M$, will be denoted by $Sp(M)$. In this paper, the complete graph of order $n$ is denoted by $K_n$. An independent set is a set of vertices in a graph, where no two vertices are adjacent. The independence number of a graph $G$ is the number of vertices of the largest independent set in $G$, denoted by $\gamma(G)$ or just $\gamma$ if there is no ambiguity. The line graph of a graph $G$, denoted by $L_G$, is the graph whose vertex set is the edge set of $G$, where two vertices of $L_G$ are adjacent, if and only if, the corresponding edges are incident in $G$. The signless Laplacian matrix and Laplacian matrix of $G$ are defined as $Q(G) = D(G) + A(G)$ and $L(G) = D(G) - A(G)$, respectively. We denote by $\mu_1$ the Laplacian spectral radius of $G$, by $q_1$ the signless Laplacian spectral radius of $G$, and by $\lambda_1$ the adjacency spectral radius or spectral radius of $G$. V. Nikiforov in Reference [1], define the matrix

$$A_\alpha (G) = \alpha D(G) + (1 - \alpha) A(G)$$

with $0 \leq \alpha \leq 1$. 

$Mathematics 2020, 8, 1668; doi:10.3390/math8101668$
Its straightforward verified that
\[ A_0(G) = A(G), \quad 2A_{1/2}(G) = Q(G), \quad A_1 = D(G), \]
and
\[ A_\alpha(G) - A_\beta(G) = (\alpha - \beta)L(G). \]

We denote by \( \rho_\alpha(G) \) to the spectral radius of \( A_\alpha(G) \) or well called the \( \alpha \)-index of \( G \). The join of two vertex disjoint graphs \( G_1 \) and \( G_2 \) is the graph obtained from the disjoint union \( G_1 \cup G_2 \) by adding new edges from each vertex in \( G_1 \) to every vertex in \( G_2 \). It is usually denoted by \( G_1 \vee G_2 \). This graph operation can be generalized in the following way: Let \( H \) be a graph of order \( k \) and \( V(H) = \{1, 2, \ldots, k\} \). Let \( \mathcal{F} = \{G_1, G_2, \ldots, G_k\} \) be a set of pairwise vertex disjoint graphs. Here, each vertex \( j \in V(H) \) is assigned to the graph \( G_j \in \mathcal{F} \). Let \( G \) be the graph obtained from the graphs \( G_1, G_2, \ldots, G_k \) and the edges connecting each vertex of \( G_i \) with all the vertices of \( G_j \), for all edge \( ij \in E(H) \). That is, \( G \) is the graph with vertex set
\[ V(G) = \bigcup_{i=1}^{k} V(G_i) \]
and edge set
\[ E(G) = \left( \bigcup_{i=1}^{k} E(G_i) \right) \bigcup \left( \bigcup_{ij \in E(H)} \{uv : u \in V(G_i), v \in V(G_j)\} \right). \]

This graph is designated the \( H \)-join (or generalized composition) of the graphs \( G_1, G_2, \ldots, G_k \) [2–4], and it is denoted by
\[ G = \bigvee_{H} \{G_j : 1 \leq j \leq k\}. \]

In Reference [5], the authors determine the unique graph with maximal \( \alpha \)-index among all connected graphs with diameter \( d \), and determine the unique graph with minimal \( \alpha \)-index among all connected graphs with given clique number. In Reference [6], the extremal graph with maximal \( \alpha \)-index with fixed order and cut vertices and the extremal tree which attains the maximal \( \alpha \)-index with fixed order and matching number are characterized. In Reference [7], the authors obtain the extremal graphs with maximal \( \alpha \)-index with fixed order and diameter at least \( k \). In References [8,9], are characterized the graphs which have the minimal spectral radius among all the connected graphs of order \( n \) and some values of the independence number \( \gamma \). In Reference [10], Nikiforov et al. shown that if \( T_\Delta \) is a tree of maximal degree \( \Delta \), then the spectral radius of \( A_\alpha(T_\Delta) \) satisfies the tight inequality
\[ \rho_\alpha(T_\Delta) < \alpha \Delta + 2(1 - \alpha)\sqrt{\Delta - 1}. \]

In Reference [11], the authors obtain the following sharp upper bound for the spectral radius of \( G \).

**Theorem 1** ([11]). Let \( G \) be a simple graph with \( n \) vertices and \( m \) edges. Let \( \delta = \delta(G) \) be the minimum degree of vertices of \( G \) and \( \lambda_1(G) \) be the spectral radius of the adjacency matrix of \( G \). Then,
\[ \lambda_1(G) \leq \frac{\delta - 1 + \sqrt{(\delta + 1)^2 + 4(2m - \delta n)}}{2}. \]

Equality holds, if and only if, \( G \) is either a regular graph or a bidegreed graph where each vertex has degree either \( \delta \) or \( n - 1 \).
In Reference [12], is presented a sharp lower bound on the signless Laplacian spectral radius of a graph in terms of independence number.

**Theorem 2 ([12]).** Let \( G \) be a graph of order \( n \) and \( \gamma(G) = \gamma \). Then

\[
q_1(G) \geq \frac{2(n - \gamma)}{\gamma}
\]

with equality, if and only if, \( n = k\gamma \) and \( G \cong \gamma K_k \).

This paper is organized in the following way. In Section 1, besides the main concepts and notation used throughout the paper we present some recent work that motivated the authors. In Section 2, for \( n = t\gamma + s \) where \( 0 \leq s < \gamma \) and \( 0 \leq \alpha < 1 \), a lower bound for the \( \alpha \)-index of graphs of order \( n \) and independence number \( \gamma \) is given, further it is shown equality cases.

In Section 3, for \( 0 \leq \alpha < 1 \), an upper bound for the \( \alpha \)-index of graphs of order \( n \), edge number \( m \) and minimal degree \( \delta \) is given, we demonstrate that the equality holds, if and only if, is either \( G \) a regular graph or a bidegreed graph where each vertex is of degree either \( \delta \) or \( n - 1 \). In Section 4, for \( 0 \leq \alpha < 1 \), we present an ordering of \( \alpha \)-index in the class of the graphs \( K_l \vee (K_p \cup K_{n-p-l}) \) where \( 1 \leq p \leq \lfloor \frac{n-l}{2} \rfloor \).

### 2. Spectral Radius and Independence Number

In this section, we present a lower bound for the spectral radius of graphs in terms of the order and independence number which generalizes and improves the lower bound presented in Theorem 2. We first present some lemmas used in the proof of our result. For general properties of the matrices \( A_\alpha(G) \) we refer the reader to Reference [1]. In particular, we frequently use the facts that \( \rho_\alpha(G) \) is non-decreasing in \( \alpha \) ([1], Proposition 4).

**Lemma 1 ([1]).** Let \( G \) be a graph of order \( n \) and \( H \) be any subgraph of \( G \). If \( 0 \leq \alpha \leq 1 \) then

\[
\rho_\alpha(H) \leq \rho_\alpha(G).
\]

**Remark 1 ([12]).** If \( S \subseteq V(G) \) is a maximal independent set of \( G \), then for each \( u \in V(G) - S \), there exists some vertex \( v \in S \) such that \( uv \in E(G) \). Moreover, for any \( w \in V(G) - (S \cup \{u\}) \) with \( uw \notin E(G) \) and \( wv \in E(G) \), there exists some vertex \( v_1 \in S - v \) such that \( uv_1 \in E(G) \) or \( wv_1 \in E(G) \).

**Remark 2 ([12]).** For a graph \( G \) on \( n \) vertices non-isomorphic to the graph \( \overline{K}_n \), we have

\[
\gamma(G) \leq \gamma(G - e) \leq \gamma(G) + 1.
\]

**Lemma 2 ([13]).** Let \( G \) be a graph of order \( n \) and \( m \) edges. Let \( 0 \leq \alpha < 1 \). Then,

\[
\rho_\alpha(G) \geq \frac{2m}{n}
\]

with equality, if and only if, \( G \) is a regular graph.

**Lemma 3.** Let \( G \) be a graph of order \( n \) and independence number \( \gamma \) with \( n = t\gamma + s \) where \( 0 \leq s < \gamma \) and \( 1 < \gamma < n \). Then \( G \cong sK_{t+1} \cup (\gamma - s)K_t \), if and only if, in \( G \) the following conditions are verified

(a) there exists \( t \) maximal independent sets \( S_1, \ldots, S_t \) and an independent set \( S_{t+1} \) of cardinality \( s \) where \( S_i \cap S_j = \phi \) for \( i, j = 1, \ldots, t + 1, i \neq j \);
each vertex of $S_i$ is adjacent to a single vertex of $S_j$ for $i, j = 1, \ldots , t + 1, i \neq j$.

Proof. Let $G$ be a graph of order $n$ and independence number $\gamma$ that verifies the conditions (a) and (b). If $t = 1$ and $s > 0$ or $t = 2$ and $s = 0$ then $G \cong sK_{t+1} \cup (\gamma - s)K_t$, the result holds. Otherwise, let $x \in S_k$, $y \in S_j$, and $z \in S_m$ where $k = 1, \ldots , t + 1; l, m = 1, \ldots , t$ and $k \neq m \neq l \neq k$. Suppose $xy \in E(G)$ and $xz \in E(G)$. We claim $yz \notin E(G)$. Suppose $yz \notin E(G)$ then by (b) $zw \in E(G)$ for some $w \in S_j, w \neq y$. By (a) $x \neq w$. Then, by (b) $(S_m - \{z\}) \cup \{x, w\}$ would be an independent set in $G$ of cardinality $\gamma + 1$ which is a contradiction. By repeated applications of the above argument we can conclude that $G \cong sK_{t+1} \cup (\gamma - s)K_t$. Conversely, if $G \cong sK_{t+1} \cup (\gamma - s)K_t$ then $G$ verify the conditions (a) and (b). The proof is complete. \qed

Lemma 4. Let $G \not\cong sK_{t+1} \cup (\gamma - s)K_t$ be a graph of order $n$ and independence number $\gamma$ with $n = t\gamma + s$ where $0 \leq s < \gamma$ and $1 < \gamma < n$, then $G$ has a proper subgraph $H$ of order $n$ and independence number $\gamma$.

Proof. Suppose $G \not\cong sK_{t+1} \cup (\gamma - s)K_t$ then $G$ does not verify some of the conditions (a) or (b) of Lemma 3. Suppose $G$ does not verify the condition (a), then the following two cases may occur:

(i) $G$ has exactly $\ell$ maximal independent sets $S_1, \ldots , S_\ell$ where $\ell < t$ and $S_i \cap S_j = \emptyset$ for $i, j = 1, \ldots , \ell, i \neq j$. Then, $\gamma(G - \bigcup_{i=1}^{\ell} S_i) < \gamma$ (otherwise, if $\gamma(G - \bigcup_{i=1}^{\ell} S_i) = \gamma$ then $G$ would have $\ell + 1$ two by two disjoint independent sets which would be a contradiction). Then, by Remark 2, we can constructed a new graph $H_1 \cong G - e$ on $n$ vertices and independence number $\gamma$, where $e \in E(G - \bigcup_{i=1}^{\ell} S_i)$, the result holds.

(ii) $G$ has exactly $t$ maximal independent sets $S_1, \ldots , S_t$ and $S_i \cap S_j = \emptyset$ for $i, j = 1, \ldots , t, i \neq j, s > 0$ and $G_1 \cong G - \bigcup_{i=1}^{t} S_i \not\cong K_1$ then we can constructed a new graph $H_2 \cong G - e$ on $n$ vertices and independence number $\gamma$, where $e \in E(G_1)$, the result holds.

Now, suppose that $G$ verify condition (a) but does not verify condition (b), this is, we assume that $G$ has $t$ maximal independent sets $S_1, \ldots , S_t$ and an independent set $S_{t+1}$ of cardinality $s$ such that $S_i \cap S_j = \emptyset$ for $i, j = 1, \ldots , t + 1$ with $i \neq j$. As $G$ does not check condition (b) there exists $v \in S_t$ and $u, w \in S_i$ for some $i, j = 1, \ldots , t + 1, i \neq j$ and $u \neq w$ such that $uv \in E(G)$ and $uw \in E(G)$.

(i) For $i = 1, \ldots , t$, by Remark 1, there exists some vertex $v_1 \in S_i - \{v\}$ such that $uv_1 \in E(G)$ or $wv_1 \in E(G)$. Suppose $uv_1 \in E(G)$. Then, we constructed a new graph $H_2 \cong G - uv$ on $n$ vertices and independence number $\gamma$, the result holds.

(ii) Suppose that each vertex of $S_i$ is adjacent to a single vertex of $S_j$ for $i, j = 1, \ldots , t$ and $j = 1, \ldots , t + 1, i \neq j$, then we use the same techniques applied in the proof from Lemma 3, we can see that $G - S_{t+1} \cong \gamma K_t$. Now, let $i = t + 1$ and $G - S_{t+1} \cong \gamma K_t$. We claim, $v$ is adjacent to all the vertices of a connected component of $G - S_{t+1}$ isomorphic to $K_t$. Otherwise, there exists $\ell_m$ in each connected component of $G - S_{t+1}$ isomorphic to $K_t$ such that $vw_m \notin E(G)$ for $m = 1, \ldots , \gamma$. So, $S = \{v, v_1, \ldots , v_\gamma\}$ would be an independent set in $G$ of cardinality $\gamma + 1$ which is a contradiction. Then, there exists $Z = \{v_1, \ldots , v_t\}$ such that $v_p \in V(G) - S_{t+1}, vw_p \in E(G)$ for $p = 1, \ldots , t$ and $v_pv_q \in E(G)$ for $p, q = 1, \ldots , t$. Thus, $u \notin Z$ or $w \notin Z$. If $u \notin Z$ then we constructed a new graph $H_2 \cong G - uv$ of order $n$ and independence number $\gamma$.

The proof is complete. \qed

Let $G$ and $H$ be two graphs of order $n$, we will say that $G$ and $H$ are comparable, if and only if, $H$ is subgraph of $G$ or $G$ is subgraph of $H$. 
Lemma 5. Let G be a graph of order n and independence number γ with $n = t\gamma + s$ where $0 \leq s < \gamma$ and $1 < \gamma < n$, then $sK_{t+1} \cup (\gamma - s)K_t$ is a subgraph of G.

Proof. Let $G_1 \cong sK_{t+1} \cup (\gamma - s)K_t$ then by Lemma 3 in $G_1$ the following conditions are verified (a) there exists $t$ maximal independent sets $S_1, \ldots, S_t$ and an independent set $S_{t+1}$ of cardinality $s$ where $S_i \cap S_j = \phi$ for $i, j = 1, \ldots, t + 1, i \neq j$ and (b) each vertex of $S_i$ is adjacent to a single vertex of $S_j$ for $i, j = 1, \ldots, t + 1, i \neq j$. Let $G_2 \cong G_1 - uv$ where $u \in S_i, v \in S_j$ and $uv \in E(G_1)$ for some $i, j = 1, \ldots, t + 1, i \neq j$. Thus, in $G_2$ some of the sets $S_i \cup \{v\}$ or $S_j \cup \{u\}$ is an independent set of cardinality $\gamma + 1$. Since $G$ is a graph of order $n$ and independence number $\gamma$ then $G$ is not a proper subgraph of $G_1$. Now, suppose $G$ and $G_1$ are not comparable graphs. By Lemma 4, $G$ has a proper subgraph $H_1$ of order $n$ and independence number $\gamma$. Clearly, $H_1 \not\cong G_1$. Then by Lemma 4, $H_1$ has a proper subgraph $H_2$ of order $n$ and independence number $\gamma$. Clearly, $H_2 \not\cong G_1$. By repeated applications of previous argument, we can conclude $K_n$ is a graph of order $n$ and independence number $\gamma$ where $1 < \gamma < n$ which is a contradiction. Hence, $G$ and $G_1$ are comparable graphs. Since $G$ is not a proper subgraph of $G_1$ then $G_1$ is a subgraph of $G$. The proof is complete.

Below we present the main result of the section which is a lower bound for the spectral radius of graphs in terms of order and independence number.

Theorem 3. Let $G$ be a graph of order $n$ and independence number $\gamma$ with $n = t\gamma + s$ where $0 \leq s < \gamma$. Let $0 \leq \alpha < 1$ then

$$\rho_\alpha(G) \geq \begin{cases} \frac{n-s}{\gamma} & \text{if } s > 0, \\ \frac{n-\gamma}{\gamma} & \text{if } s = 0. \end{cases}$$

- If $s = 0$, then the equality holds, if and only if, $G \cong \gamma K_t$.
- If $s > 0$, then the equality holds if $G \cong sK_{t+1} \cup (\gamma - s)K_t$.

Proof. Let $G$ be a graph of order $n$ and independence number $\gamma$ with $n = t\gamma + s$ where $0 \leq s < \gamma$. First consider $\gamma = 1$ then $s = 0$ and $n = t$. By Remark 1, $G \cong K_n \cong \gamma K_t$ the result holds. Now, let $\gamma = n$ then $s = 0$ and $t = 1$. Then, $G \cong K_n \cong \gamma K_t$ the result is true. Now, we assume $1 < \gamma < n$. By Lemma 5, $sK_{t+1} \cup (\gamma - s)K_t$ is a subgraph of $G$. Clearly, for $G^* \cong sK_{t+1} \cup (\gamma - s)K_t$, we have $\rho_\alpha(G^*) = \frac{n-s}{\gamma}$ if $s > 0$, and $\rho_\alpha(G^*) = \frac{n-\gamma}{\gamma}$ if $s = 0$. By Lemma 1,

$$\rho_\alpha(G) \geq \begin{cases} \frac{n-s}{\gamma} & \text{if } s > 0, \\ \frac{n-\gamma}{\gamma} & \text{if } s = 0. \end{cases}$$

Suppose the equality holds, $s = 0$ and $G \not\cong G^*$ then the edge number $m$ of $G$ is greater than $\frac{\gamma t(t-1)}{2}$. By Lemma 2, $\rho_\alpha(G) \geq \frac{2m}{n} > \frac{\gamma t(t-1)}{2} = \frac{n-\gamma}{\gamma}$ which is a contradiction. The proof is complete.

The following result which is a direct consequence of Theorem 3, presents a lower bound for the signless Laplacian spectral radius and this in turn improves the bound of Theorem 2.
Corollary 1. Let $G$ be a graph of order $n$ and independence number $\gamma$ with $n = t\gamma + s$ where $0 \leq s < \gamma$, then

$$q_1(G) \geq \begin{cases} \frac{2(n-s)}{\gamma} & \text{if } s > 0, \\ \frac{2(n-\gamma)}{\gamma} & \text{if } s = 0. \end{cases}$$

- If $s = 0$, then the equality holds, if and only if, $G \cong \gamma K_t$.
- If $s > 0$, then the equality holds if $G \cong sK_{t+1} \cup (\gamma - s)K_t$.

Proof. Taking $\alpha = \frac{1}{2}$ then $2A_\alpha (G) = Q (G)$, by Theorem 3 the result holds. $\square$

3. Spectral Radius and Minimal Degree

In this section, we provide the necessary definitions and lemmas on which our main results rely. We begin with some simple matrix results. Let $B = (b_{ij})$ be an $m \times n$ matrix. Then $s_i(B)$ will denote the $i$-th row sum of $B$, that is, $s_i(B) = \sum_{j=1}^n b_{ij}$, where $1 \leq i \leq m$.

Lemma 6 ([14]). Let $B$ be a real symmetric $n \times n$ matrix and $\lambda$ be an eigenvalue of $B$, with an eigenvector $x$ all of whose entries are nonnegative. Then

$$\min_{1 \leq i \leq n} s_i(B) \leq \lambda \leq \max_{1 \leq i \leq n} s_i(B).$$

Moreover, if the row sums of $B$ are not all equal and if all entries of $x$ are positive, then both inequalities above are strict.

An immediate consequence is the following result.

Lemma 7. Let $G$ be a simple connected graph of order $n$ with $A_\alpha (G) = A_\alpha$ where $0 \leq \alpha < 1$. Let $P$ be any polynomial and $R_v(P(A_\alpha))$ be the row sum of $P(A_\alpha)$ corresponding to $v \in V(G)$, then

$$\min_{v \in V(G)} R_v(P(A_\alpha)) \leq P(\rho_\alpha(G)) \leq \max_{v \in V(G)} R_v(P(A_\alpha)).$$

Both equalities above holds, if and only if, the row sums of $P(A_\alpha)$ are all equal.

As a consequence of Lemma 7, we obtain the following result which generalize Theorem 1.

Theorem 4. Let $G$ be a simple connected graph of order $n$ and minimal degree $\delta$ with $m$ edges and $0 \leq \alpha < 1$. Then

$$\rho_\alpha(G) \leq \frac{\delta - 1 + \alpha + \sqrt{(\delta + 1 - \alpha)^2 + 4(2m - n\delta)(1 - \alpha)}}{2}.$$ 

The equality holds, if and only if, $G$ is either a regular graph or a bidegreed graph where each vertex has degree either $\delta$ or $n-1$. 
**Proof.** Let \( G \) be a graph of order \( n \), minimal degree \( \delta \) and \( m \) edges and \( R_v (A_a) \) be the row sum of \( A_a \) corresponding to \( v \in V(G) \) where \( A_a \) denote the matrix \( A_a(G) \). We can easily see that \( R_v (A_a) = d_v \) for \( v \in V(G) \). Calculating the row sum of \( A_a^2 \) for \( v \in V(G) \), we have

\[
R_v \left( A_a^2 \right) = ad_v^2 + (1 - \alpha) \sum_{u \sim v} d_u = ad_v^2 + (1 - \alpha) \left( 2m - d_v - \sum_{u \in V, u \neq v} d_u \right).
\]

Thus,

\[
R_v \left( A_a^2 \right) \leq ad_v^2 + (1 - \alpha) \left( 2m - d_v - (n - d_v - 1) \delta \right).
\]

Thereby,

\[
R_v \left( A_a^2 \right) - ((1 - \alpha) (\delta - 1) + ad_v) R_v (A_a) \leq (1 - \alpha) (2m - (n - 1) \delta).
\]

For the linearity,

\[
R_v \left( A_a^2 - ((1 - \alpha) (\delta - 1) + ad_v) A_a \right) \leq (1 - \alpha) (2m - (n - 1) \delta).
\]

Taking \( P(x) = x^2 - ((1 - \alpha) (\delta - 1) + ad_v) x \) in Lemma 7, we have

\[
\rho_a^2(G) - ((1 - \alpha) (\delta - 1) + ad_v) \rho_a(G) - (1 - \alpha) (2m - (n - 1) \delta) \leq 0.
\]

In particular,

\[
\rho_a^2(G) - (\delta - 1 + \alpha) \rho_a(G) - (1 - \alpha) (2m - (n - 1) \delta) \leq 0.
\]

Solving the inequality (2) for \( \rho_a(G) \), we obtain

\[
\rho_a(G) \leq \frac{\delta - 1 + \alpha + \sqrt{(\delta + 1 - \alpha)^2 + 4 (2m - n \delta) (1 - \alpha)}}{2}.
\]

Suppose the equality in (3) holds, then all the inequalities in the above argument must be equalities. This implies that

\[
2m - d_v - (n - d_v - 1) \delta = \sum_{u \sim v} d_u
\]

for all \( v \in V(G) \), that is,

\[
\sum_{u \in V, u \neq v} d_u = (n - d_v - 1) \delta.
\]

for all \( v \in V(G) \). Now, suppose \( u_1 \) and \( v_1 \) are two non-adjacent vertices in \( G \) then \( d_{v_1} < n - 1 \). By (4), we have \( d_{u_1} = \delta \). Analogously, we can prove that \( d_{v_1} = \delta \). Hence, the affirmation “Any pair of non-adjacent vertices in \( G \) have degree \( \delta \)” is true. Now, if there exists \( v \in V(G) \) such that \( d_v > \delta \) then by above affirmation, we conclude \( v \) is adjacent to \( u \) for all \( u \in V(G) \) with \( u \neq v \), this is, \( d_v = n - 1 \) which implies either \( G \) is a regular graph of degree \( \delta \) or \( G \) is a bidegreed graph where each vertex has degree either \( \delta \) or \( n - 1 \). Conversely, if \( G \) is a regular graph then the equality holds. Now, suppose \( G \) is a bidegreed graph where each vertex has degree \( \delta \) or \( n - 1 \).
proof. Taking then \( q_i \leq 2d - n \), since \( R_v(A_{\lambda}) = d_v \), by (1) we have

\[
R_v \left( A_{\lambda}^2 \right) - ((1 - \alpha) (\delta - 1) + \alpha \delta) R_v(A_{\lambda}) = (1 - \alpha)(2m - d_v - (\delta - 1)d_v)
\]

\[
= (1 - \alpha)(2m - n - (n - 1)\delta).
\]

Let \( v \in V(G) \) such that \( d_v = \delta \), since \( R_v(A_{\lambda}) = d_v \), by (1) and (4) we have

\[
R_v \left( A_{\lambda}^2 \right) - ((1 - \alpha) (\delta - 1) + \alpha \delta) R_v(A_{\lambda}) = (1 - \alpha)(2m - d_v - \sum_{u \neq v, u \neq v} d_u - (\delta - 1)d_v)
\]

\[
= (1 - \alpha)(2m - \delta - (n - 1 - \delta)\delta - (\delta - 1)\delta)
\]

\[
= (1 - \alpha)(2m - (n - 1)\delta).
\]

Now, taking \( P(x) = x^2 - ((1 - \alpha) (\delta - 1) + \alpha \delta) x \) in Lemma 7, we have

\[
\rho_{\alpha}^2(G) - ((1 - \alpha) (\delta - 1) + \alpha \delta) \rho_{\alpha}(G) - (1 - \alpha)(2m - (n - 1)\delta) = 0.
\]

Hence,

\[
\rho_{\alpha}(G) = \frac{\delta - 1 + \alpha + \sqrt{(\delta + 1 - \alpha)^2 + 4(2m - n\delta)(1 - \alpha)}}{2}.
\]

The proof is complete. \( \square \)

**Corollary 2.** Let \( G \) be a graph of order \( n \) and minimal degree \( \delta \) with \( m \) edges then

\[
q_1 \leq \frac{2\delta - 1 + \sqrt{8(2m - n\delta) + (2\delta + 1)^2}}{2}.
\]

Equality holds, if and only if, \( G \) is either a regular graph or a bidegree graph where each vertex has degree either \( \delta \) or \( n - 1 \).

**Proof.** Taking \( \alpha = \frac{1}{2} \) then \( 2A_{\alpha}(G) = Q(G) \), by Theorem 4 the result holds. \( \square \)

**Lemma 8 ([15,16]).** Let \( G \) be a graph of order \( n \) with \( m \geq 1 \) edges. Let \( q_i \) be the \( i \)-th greatest signless Laplacian eigenvalue of \( G \) and \( \lambda_i(L_G) \) be the \( i \)-th greatest eigenvalue of the line graph of \( G \). Then

\[
q_i = \lambda_i(L_G) + 2,
\]

for \( i = 1, 2, \ldots, k \), where \( k = \min\{n, m\} \). In addition, if \( m > n \), then \( \lambda_i(L_G) = -2 \) for \( i \geq n + 1 \) and if \( n > m \), then \( q_i = 0 \) for \( i \geq m + 1 \).

As a direct consequence of Corollary 2 and Lemma 8, we obtain the following result.

**Corollary 3.** Let \( G \) be a graph of order \( n \) and minimal degree \( \delta \) with \( m \) edges then

\[
\lambda_1(L_G) \leq \frac{2\delta - 5 + \sqrt{8(2m - n\delta) + (2\delta + 1)^2}}{2}.
\]
Equality holds, if and only if, \( G \) is either a regular graph or a bidegreed graph where each vertex has degree \( \delta \) or \( n - 1 \).

4. Monotonicity of the \( \alpha \)-Indices of Graphs with \( 0 \leq \alpha < 1 \)

In this section, for \( 0 \leq \alpha < 1 \), we present an ordering of \( \alpha \)-indices in the class of the graphs \( G_p \equiv K_j \vee (K_p \cup K_{n-p-j}) \) where \( 1 \leq p \leq \lceil \frac{n-l}{2} \rceil \). The graphs \( G_p \) plays an important role in the representation of graphs that relate the join operation between an arbitrary family of graphs, in particular maximize some topological indices of graphs in terms of edge connectivity and vertices connectivity such as Energy, Estrada index, Spread (see References \([17–19]\)). Furthermore, in graphs of communication or transportation networks, the edge connectivity is an important measure of reliability, the study of the line graph of these graphs is relevant. In Theorem 8 \([20]\), for \( 1 \leq p \leq \lceil \frac{n-l}{2} \rceil \) is presented an ordering between the spectral radii of the distance matrices \( D_\alpha(G_p) \) where \( \alpha \in (\bar{\alpha}, 1) \), being \( \bar{\alpha} = \max\{\alpha_p : 2 \leq p \leq \lceil \frac{n-l}{2} \rceil \} \) and \( \alpha_p \) the unique zero of the function \( e(x, \alpha) = (4\alpha - 3)x + (a^2(2l - 4n) + \alpha(3n - 3l + 4) + l - 3) \) in the interval \( \left( \frac{3}{4}, \frac{3n-l}{4n-2l} \right) \). In this section, we prove that this same order is conserved for the spectral radii of the matrices \( A_\alpha(G_p) \) with \( \alpha \in [0, 1) \). We begin presenting a result for the spectrum of the matrices \( A_\alpha(G_p) \) with \( \alpha \in [0, 1] \). In Theorem 5 \([2]\), the spectrum of the adjacency matrix of the \( H \)-join of regular graphs is obtained. The version of this result for the matrices \( A_\alpha \) with \( 0 \leq \alpha < 1 \) is given below, its proof is similar.

**Theorem 5.** Let \( G \equiv \bigvee_H \{G_j : j \in V(H)\} \) where \( H \) is a graph of order \( k \) and \( G_j \) is a \( r_j \)-regular graph of order \( n_j \) for \( j = 1, \ldots, k \). Then, the spectrum of the matrix \( A_\alpha(G) \) with \( 0 \leq \alpha < 1 \) is

\[
\bigcup_{G_j \neq K_1} \{\lambda : \lambda \in Sp(A_\alpha(G_j) + s_j I_{n_j}) - \{r_j + s_j\} \} \cup Sp(M(G))
\]

where \( M(G) \) is the matrix of order \( k \) given by

\[
M(G) = \begin{bmatrix}
  a_{s_1} + r_1 & \delta_{12} \sqrt{n_1 n_2} & \cdots & \delta_{1k} \sqrt{n_1 n_k} \\
  \delta_{12} \sqrt{n_1 n_2} & a_{s_2} + r_2 & \cdots & \cdots & \cdots \\
  \vdots & \vdots & \ddots & \ddots & \ddots \\
  \delta_{1k} \sqrt{n_1 n_k} & \cdots & \delta_{(k-1)k} \sqrt{n_{k-1} n_k} & a_{s_k} + r_k \\
\end{bmatrix}
\]

with

\[
\delta_{ij} = \begin{cases} 
  1 - \alpha & \text{if } ij \in E(H) \\
  0 & \text{otherwise},
\end{cases}
\]

and

\[
s_j = \sum_{j \in E(H)} n_j.
\]

Let \( l \) and \( n \) be fixed positive integer and \( p \) be a positive integer such that \( 1 \leq p \leq \lceil \frac{n-l}{2} \rceil \), by \((5)\) we have

\[
M(G_p) = \begin{bmatrix}
  a(n - l) + l - 1 & (1 - \alpha) \sqrt{l p} & (1 - \alpha) \sqrt{l(n - l - p)} \\
  (1 - \alpha) \sqrt{l p} & al + p - 1 & 0 \\
  (1 - \alpha) \sqrt{l(n - l - p)} & 0 & n - p - (1 - \alpha)l - 1
\end{bmatrix}.
\]

We remember that the eigenvalues of \( A_\alpha(K_n) \) are \( s - 1 \) and \( as - 1 \) with multiplicity \( s - 1 \). The following result is a direct consequence of Theorem 5.
**Theorem 6.** Let and the eigenvalues of the matrix $M$

**Lemma 9.** ([21]) The characteristic polynomial of $M$

**Proof.** Since $M$ the matrices $\rho$ and $\beta$ respectively, then $\alpha$ is the largest eigenvalue of $M(g_p)$.

For $n$ $(\alpha(G) = x^Hx, if and only if, x is an associated eigenvector to \alpha(G)$; and $\beta(G) = x^Hx, if and only if, x is an associated eigenvector to $\beta(G)$.

The following Remark is an immediate consequence of Lemma 9.

**Remark 3.** For $0 \leq \alpha < 1$ and $1 \leq p \leq \lfloor n-1 \rfloor$, the spectral radius of the matrix $M(G_p)$ is not less than its diagonal entries.

As a direct consequence of Corollary 4 and Remark 3, we have

**Lemma 10.** For $0 \leq \alpha < 1$ and $1 \leq p \leq \lfloor n-1 \rfloor$, the spectral radius of the matrix $M(G_p)$ is the $\alpha$-index of $G_p$.

One can easily verify the following result.

**Lemma 11.** The characteristic polynomial of $M(G_p)$ with $0 \leq \alpha < 1$ and $1 \leq p \leq \lfloor n-1 \rfloor$, is given by

$$f_{p,a}(x) = x^3 + (3 - n - \alpha(l + n))x^2 + (\alpha^2n + \alpha((n - 2)(l + n)) + n(p - 2) + p(l + p + 3)x + l\alpha^2(2p(n - l - p) - n(n - 1)) + \alpha((n + l)(n - 1) - p(n + 3l)(n - p - l)) + p(l + 1)(n - p - l) - n + 1. $$

**Theorem 6.** Let $0 \leq \alpha < 1$ and $1 \leq p \leq \lfloor n-1 \rfloor - 1$. Then,$$
\rho_{a}(G_{p+1}) < \rho_{a}(G_p).
$$

**Proof.** Since $M(G_p)$ and $M(G_{p+1})$ are nonnegative irreducible matrices then its spectral radii are simple eigenvalues, we can assume $\rho_{a}(G_p) = \eta_1 > \eta_2 \geq \eta_3$ and $\rho_{a}(G_{p+1}) = \gamma_1 > \gamma_2 \geq \gamma_3$ are the eigenvalues of the matrices $M(G_p)$ and $M(G_{p+1})$, respectively.
Hence,
\[
f_{p+1,a}(x) - f_{p,a}(x) = \prod_{j=1}^{3}(x - \gamma_j) - \prod_{j=1}^{3}(x - \eta_j)\]
\[= (n - l - 2p - 1)(x + 2\alpha^2 - \alpha(n + 3l) + l + 1).
\] (6)

We claim \(\rho_a(G_p) > \rho_a(G_{p+1})\). Otherwise, if \(\rho_a(G_p) \leq \rho_a(G_{p+1})\) then \(\rho_a(G_{p+1}) \geq \eta_j\), for all \(j\). Taking \(x = \rho_a(G_{p+1})\) in (6), we obtain
\[
0 \geq -\prod_{j=1}^{3}(\rho_a(G_{p+1}) - \eta_j)
\]
\[= (n - l - 2p - 1)(\rho_a(G_{p+1}) + 2\alpha^2 - \alpha(n + 3l) + l + 1)
\]
\[\geq (n - l - 2p - 1)(\alpha(n - l) + l - 1 + 2\alpha^2 - \alpha(n + 3l) + l + 1)
\]
\[\geq 2(n - l - 2p - 1)(\alpha - 1)^2
\]
\[> 0
\]
which is a contradiction. Then, we conclude \(\rho_a(G_p) > \rho_a(G_{p+1})\) for all \(1 \leq p \leq \lfloor \frac{m-l}{2} \rfloor - 1\). \(\square\)
