**Abstract**

**Background:** Task-shifting and eHealth have been proposed as ways of approaching the mental health treatment gap in low and middle-income countries (LMIC). The Latin America Treatment & Innovation Network in Mental Health (LATIN-MH) developed CONEMO (Emotional Control), a behavioral intervention used to treat depressive symptoms in a sample of patients with diabetes and hypertension in Sao Paulo, Brazil. The intervention uses task shifting and is delivered via a smartphone app. The effectiveness of this intervention was tested in two randomized trials in these countries.

**Aim:** This paper aims to present the protocol for a study that will explore perceived barriers and facilitators to implementing this intervention to help future scale-up.

**Methods:** We will conduct qualitative research with users of the CONEMO intervention and health professionals who participated directly and indirectly in the trial in Brazil. We will use semi-structured interviews, and we will adopt the Consolidated Framework for Implementation Research (CFIR) for data analysis.

**Discussion:** Task-shifting and eHealth are potentially important tools to help decrease the mental health treatment gap in Latin America. This study will increase our understanding of the factors which may facilitate or hinder the implementation of mobile behavioral mental health interventions, using task-shifting, within LMICs. Findings could be used in future design and planning to facilitate successful implementation and treatment.
**Keywords:** Mental Health, Depression, Chronic diseases, Mobile Intervention, e-health

Registration in Clinical Trials ([www.clinical.trials.gov](http://www.clinical.trials.gov))

NCT028406662

### Contributions to the literature

- The research is important for the use of the Consolidated Framework for Implementation Research in the primary care context of low and middle-income countries, like the Brazil.
- Thesis findings will can contribute to think an effective implementation that decrease mental health treatment gap in primary care.
### Authors' contributions

HC and PM conceived the design of the study and drafted the protocol paper. MC contributed to the design of the study. All authors wrote, read, commented, and approved the final manuscript.

### Administrative information

Name and contact information for the trial sponsor (5b)

NIMH – National Institute of Mental Health

Source: https://www.nimh.nih.gov/about/organization/gmh/globalhubs/index.shtml.

Role of sponsor (5c)

*NIMH established the Collaborative Hubs for International Research on Mental Health (CHIRMH) to increase the research base for mental health interventions in LMICs through the integration of findings from translational, clinical, epidemiological, and/or policy research. The program aims to expand research activities in LMICs to provide the necessary knowledge, tools, and sustainable research-based strategies for use by government agencies, non-governmental organizations, and health care institutions to reduce the mental health treatment gap. Lessons learned from these contexts can inform mental health service delivery in other low-resource settings. As a group, awardees constitute a collaborative
network of regional hubs for mental health research in Africa, Asia, and Latin America, with capabilities for answering research questions (within and across regions) aimed at improving mental health outcomes for men, women, and children. Each hub supports research on task-shifting/task-sharing for the delivery of mental health services and provides research capacity-building opportunities. Hub teams are interdisciplinary, with strong interests in increasing the capacity of mental health services; enhancing collaborative learning and development; integrating local, state and national health interventions, and building relationships with governmental, non-governmental, and community-based stakeholders.” The five hubs are Africa Focus on Intervention Research for Mental Health - AFFIRM; Latin America Treatment and Innovation Network for Mental Health - LATIN-MH; Partnership for Mental Health Development in Sub-Saharan Africa - PaM-D; Regional Network for Mental Health Research in Latin America - RedeAmerica; South Asian Hub for Advocacy, Research & Education on Mental Health - SHARE.

**Background**

Mental health problems often coexist with physical health difficulties. Rates of depression in populations with chronic disease are found to be higher than those in the general community. In Brazil, the prevalence rate of depression is 4.1%, rising to 7.5% in those with hypertension and 8.6% in those with diabetes (Munhoz et al. 2016). The estimated prevalence of the major depressive disorder among adults in Sao Paulo is 9.4%. In Brazil, almost 80% of those experiencing depression do not receive any treatment, and of those who do, the most common treatment is medication without follow-up (Lopes et al. 2016), which creates a mental health treatment gap.

Currently, there is an increasing global demand for mental health care and a lack of specialized human resources to meet this need in LMICs, especially within primary and secondary care. Evaluation of task-shifting in mental health settings has shown task exchange or delegation to be an effective strategy to
cope with this demand (Agyapong et al. 2015). Active service user participation and the use of trained non-specialists could be essential tools to increase access to mental health care (Patel et al. 2010). Collaborative care for depression has also been found to be more effective than usual care, reinforcing the idea that integration among health professionals is likely better than clinical or educational guidelines alone (Patel et al. 2010).

Task-shifting is a strategy to delegate tasks usually performed by professionals with higher qualifications to people with a lower level of formal education or training (Verdeli 2016; Joshi et al. 2014). It creates a new workforce with specific training for particular tasks and offers a pragmatic response to health worker shortages (Joshi et al. 2014; Agyapong et al. 2015).

The Latin America Treatment and Innovation Network for Mental Health (LATIN-MH) has developed a mobile behavioral intervention (CONEMO) to treat depressive symptoms in patients with diabetes or hypertension, which utilizes task shifting. CONEMO is a low-intensity intervention that is based on behavioral activation and offered through a smartphone application. It comprises 18 sessions delivered three times a week for six weeks, with the support and monitoring of a Nurse Assistant. The Nurse Assistants (NAs) were recruited to be part of the task-shifting workforce and were responsible for teaching participants to use the CONEMO app, monitoring adherence to the intervention, helping participants with technological issues, and making telephone contacts to support and motivate participants. The NAs were trained and supervised by Psychologists. CONEMO is one of the first smartphone applications that offer psychoeducational intervention in mental health, developed and tested in LMICs. The clinical effectiveness of the response is being evaluated in two RCTs (Randomized Control Trials) comparing CONEMO to enhanced usual care.

If the CONEMO intervention is shown to be effective, it could be an essential tool in reducing the mental health treatment gap. To make this successful, it is important to assess the barriers and facilitators to implementation. This would enable necessary adjustments to be made to make the proposal viable and should help guarantee the best use of funds and resources.

To improve intervention success, it is important to adapt implementation strategies to the local context. Psychological interventions must be accepted by the patients and professionals involved in the process (Atif et al. 2016).
Professional and user opinions, perceptions or understanding of intervention can influence implementation and outcome (Agyapong et al. 2016; Knowles et al. 2013). Efficacy of treatment is proven according to cultural sensitivity, contextual relevance, and public comprehension of the importance and use of this treatment (Patel et al. 2010).

Aim

This study aims to explore the perceived barriers and facilitators to implementing a smartphone delivered intervention with task shifting in the treatment of depressive symptoms in people with diabetes and or hypertension.

This protocol is part of the RCT and is linked to the "Shared Research Project" of the five HUBs funded by the National Institute of Mental Health. The mission of this shared research is to explore the implementation of task-shifting programs in mental health care settings in low and middle-income countries. The five research groups are working on qualitative research to investigate critical facilitators and barriers to their interventions, according to the singularities and context of those involved (Minayo & de Souza Minayo, 2012). This paper focus on the results of the Sao Paulo branch of the shared research.

Method

We will conduct a cross-sectional qualitative study using semi-structured interviews to explore the barriers and facilitators to successful implementation of CONEMO, from a professional and user perspective.

Sample

We will interview individuals who either participated in the RCTs as a participant (patient of the health care system) or as health care professional involved directly or indirectly in the trial (Nurse Assistant or Manager). The interviewees range from patients from intervention groups, professionals, managers and policymakers invited to acquire their opinion about this proposal and others alike.

A total of 880 participants in the Sao Paulo RCT were recruited from 20 family health units (FHU), using cluster randomization.
For this study, the user’s sample constitution criteria will be non-probabilistic, using the saturation theory to determine the final sample (Mason, 2010). This will enable us to reach a representative sample, with a diverse range of experience with the RCT process.

**Interviews Guide**

The semi-structured interviews will be based on a standard proposal from the "Collaborative HUBs Shared Research" to facilitate the comparison of data across HUBs. The proposal has been translated and culturally adapted by the Latin-MH research team.

There will be four interview templates, one for each participant category: participants from intervention, NAs, Managers, and policymakers. A summary of the RCT proposal will be presented to policymakers before the interview since they did not participate in the RCT.

**Procedures**

**Participant selection**

The following criteria will be used for selecting participants, respecting the proportion in each category:

a) Adherence to intervention:

   i) No adherence: participants who completed only the training session;
   
   ii) Medium adherence: participants who completed up to 50% of sessions;
   
   iii) High adherence: participants who completed more than 50% of sessions.

b) Geographic area: participants from all FHU’s in Sao Paulo

The list of relevant characteristics and the number of participants required will be sent to the Data Center Coordination (DCC). The DCC will then provide a list of potential participants. We will use the software Stata 13 to carry out a selection by drawing, respecting the established criteria. The health professionals will be selected based on the experience of the research team based on their engagement.
Data Collection

Participants will be contacted by phone, and those interested in taking part will be interviewed by the research team, who will give a detailed explanation about the research, allowing questions, and obtaining informed consent. Interviews will be face-to-face, recorded using a portable voice recorder, and subsequently transcribed verbatim. Interviews will take place confidentially, in a private room, free from noise and distraction.

Data Analysis

After transcription, interviews will be analyzed using QSR International Pty Ltd’s N-VIVO 12 Pro For Windows, software to support the organization and analysis of qualitative interview data.

The Consolidated Implementation Research Framework (CFIR) will be used to guide the analysis to understand the facilitators and barriers to implementation. The CFIR is a conceptual explanatory framework used to identify constructs and mechanisms which may influence implementation and effectiveness (Damschroder et al. 2009).

Discussion

Task-shifting and e-health are viable strategies for increasing access to mental health care and reducing the treatment gap. CONEMO is one such intervention, and if shown to be effective, it would be fundamental to investigate which aspects can facilitate or hinder its implementation.

Lawton et al. (2015) highlight that the emotional aspects of people who work in the trial/intervention should be taken into account to ensure they are supported and able to conduct their tasks adequately (Lawton et al. 2015). Emotional challenges associated with conflicts between research and clinical activities may be stressful. Professional’s opinions and perceptions must be taken into account regarding any difficulties faced, for example, in handling the intervention, workload, or relationship with participants.
This study is fundamental to help identify and understand the facilitators and barriers to implementation of the CONEMO intervention from the perspective of those involved. Analyzing the social, cultural and territorial representations related to this intervention will allow the design of a customized proposal, with higher chances of being accepted and, therefore, successful.

**Trial Status**

Recruitment closed.

**List of abbreviations**

| Abbreviation | Description |
|--------------|-------------|
