Abstract
We consider the problem of partitioning a graph into a non-fixed number of non-overlapping subgraphs of maximum density. The density of a partition is the sum of the densities of the subgraphs, where the density of a subgraph is its average degree, that is, the ratio of its number of edges and its number of vertices. This problem, called Dense Graph Partition, is known to be NP-hard on general graphs and polynomial-time solvable on trees, and polynomial-time 2-approximable.

In this paper we study the restriction of Dense Graph Partition to particular sparse and dense graph classes. In particular, we prove that it is NP-hard on dense bipartite graphs as well as on cubic graphs. On dense graphs on $n$ vertices, it is polynomial-time solvable on graphs with minimum degree $n - 3$ and NP-hard on $(n - 4)$-regular graphs. We prove that it is polynomial-time $4/3$-approximable on cubic graphs and admits an efficient polynomial-time approximation scheme on graphs of minimum degree $n - t$ for any constant $t \geq 4$.

1 Introduction

The research around communities in social networks can be seen as a contribution to the well-established research of clustering and graph partitioning. Graph partitioning problems have been intensively studied with various measures in order to evaluate clustering quality, see e.g. [17, 18, 10, 6] for an overview. In the context of social networks, a ‘community’ is a collection of individuals who are relatively well connected compared to other parts of the social network graph. A ‘community structure’ then corresponds to a partition of the whole social network into communities.

We consider a classical definition of the density of a (sub)graph (see, for example, [12, 15, 8]) given by its average degree, that is, the ratio between its number of edges and its number of vertices. For this definition of density, there are several papers on finding the densest subgraph. This problem was shown solvable in polynomial time by Goldberg [12] but if the size of the subgraph is a part of the input, the problem called $k$-DENSEST SUBGRAPH becomes NP-hard even restricted to bipartite or chordal graphs [7]. The approximability of $k$-DENSEST SUBGRAPH was also studied, see [14, 9, 4].

In this paper, we study the problem MAX DENSE GRAPH PARTITION that models finding a community structure, that is, finding a dense partition. More precisely, given an undirected graph $G$, we aim to find a partition $\mathcal{P} = \{V_1, \ldots, V_k\}$, $k \geq 1$, of the vertices of $G$, such that
Dense Graph Partitioning on sparse and dense graphs

The following overview summarises the results achieved in this paper concerning Max Dense Graph Partition (MDGP).

- MDGP is trivially solvable on graphs of maximum degree 2, we prove its NP-hardness for 3-regular (cubic) graphs.
- We establish that on bipartite complete graphs an optimal partition consists of one part, that is the whole graph. Moreover if the size of the two independent sets are relatively prime numbers then this optimal solution is unique. We use this result to show that

sum of the densities of the subgraphs $G[V_i]$ is maximized. We denote the sum of the densities of the subgraphs $G[V_i]$ by $d(P)$, and call this the density of the partition $P$.

Note that the general concept of a community structure does not put any restriction on the number of communities. We therefore address the problem Max Dense Graph Partition of finding a partition of maximum density, without fixing the number of classes of the partition. Indeed, when the number of classes is given, the problem is a generalization of a partition into $k$ cliques. By not fixing the number of classes, Max Dense Graph Partition differs from partitioning into cliques: observe that while there exists a partition into exactly $k$ sets of density $(n - k)/2$ if and only if the input graph can be partitioned into $k$ cliques (see Lemma 2), there can be a partition into less than $k$ sets with a density even higher than $(n - k)/2$ even if the input cannot be partitioned into $k$ cliques. As an example, consider a complete graph of an even number $n$ of vertices and turn four of the vertices into an independent set by removing all edges among them. The resulting graph cannot be partitioned into 3 cliques (at least one set contains two of the four independent vertices), but it has a partition into two sets of equal cardinality with density $(n - 2)/2 - 4/n$.

Darley et al. [8] studied the problem Max Dense Graph Partition, and its complement Min Sparse Graph Partition. They defined the sparsity of a partition $P$ as $F(P) = \frac{1}{|P|} + d(P)$ and the problem Min Sparse Graph Partition as finding a partition of a given undirected graph $G$ such that the sparsity of the partition is minimized. Observe that Max Dense Graph Partition and Min Sparse Graph Partition are dual in the sense that solving the first one on a graph $G$ is the same as solving the second one on the complement of $G$. In [8] it is shown that both problems are NP-complete, and that there is no constant factor approximation for Min Sparse Graph Partition unless $P = NP$. Moreover, a polynomial time algorithm for Max Dense Graph Partition on trees is given. We point out that their proof of NP-completeness is a polynomial-time reduction from $k$-COLORING. By construction, the same reduction when starting from 3-COLOURING on graphs of degree at most 4 (proved NP-complete in [11]) yields as instance of Max Dense Graph Partition a graph on $n$ vertices and of minimum degree greater than $n - 4n^{4/5}$. Thus it follows that Max Dense Graph Partition is NP-complete restricted to graphs of minimum degree $n - 4n^{4/5}$.

Aziz et al. [2] studied the problem Fractional Hedonic Game, and more particularly the Max Utilitarian Welfare problem as the simple symmetric version of the game defined as follows. Let $N$ be a set of agents, the utility of $i \in N$ in a coalition $S \subseteq N$ is $u_i(S) = \frac{1}{|S|} \sum_{j \in S} u_i(j)$ where $u_i(j)$ is such that $u_i(j) \in \{0, 1\}$ for a simple game and $u_i(j) = u_j(i)$ for a symmetric one. For Max Utilitarian Welfare one tries to find a partition $C$ of $N$ into coalitions that maximizes $\sum_{S \in C} \sum_{i \in S} u_i(S)$. This game can be seen as a graph $G$ where agents are vertices and there is an edge between two agents $i$ and $j$ if and only if $u_i(j) = 1$. In this context, $u_i(S) = \frac{1}{|S|} \sum_{j \in S} u_i(j) = \frac{1}{|S|} \text{deg}_G[S](i)$. We deduce that $\sum_{S \in C} \sum_{i \in S} u_i(S) = \frac{1}{|C|} \sum_{S \in C} \sum_{i \in S} \text{deg}_G[S](i) = \frac{1}{|C|} \sum_{S \in C} 2|E(S)| = 2 \cdot d(C)$. Hence, the problems Max Utilitarian Welfare and Max Dense Graph Partition are equivalent to within a constant, which means that the 2-approximation for the former given in [2] directly translates to the latter.

Our contributions. The following overview summarises the results achieved in this paper concerning Max Dense Graph Partition (MDGP).

- MDGP is trivially solvable on graphs of maximum degree 2, we prove its NP-hardness for 3-regular (cubic) graphs.
- We establish that on bipartite complete graphs an optimal partition consists of one part, that is the whole graph. Moreover if the size of the two independent sets are relatively prime numbers then this optimal solution is unique. We use this result to show that
MDGP is NP-hard on dense bipartite graphs.
- MDGP is trivial on complete graphs since the optimal solution is the whole graph as one part of the partition. Moreover, as we previously explained, it is NP-hard on graphs of minimum degree $n - 4n^{4/5}$. We show that for graphs of minimum degree $\delta \geq n - 3$, the problem is solvable in polynomial time and any optimal solution has two parts. Moreover on $(n - 4)$-regular graphs, the problem becomes NP-hard.
- We further give improves on the 2-approximation for MDGP on general graphs [2] for specific sparse and dense graph classes. In particular, we show that MDGP admits a polynomial-time 4/3-approximation on cubic graphs. Moreover, as we previously explained, it is NP-hard on graphs of degree of the vertex with the greatest number of edges incident to it. The minimum degree of a graph, denoted by $\delta(G)$, is the degree of the vertex with the least number of edges incident to it. The minimum degree of $G$, denoted by $\delta(G)$, is the degree of the vertex with the least number of edges incident to it. For any vertex $v \in V$, $N_G(v)$ is the set of neighbors of $v$ in $G$ and $N_G(v) = N_G(v) \cup \{v\}$. Moreover, $N_G(S) = \bigcup_{v \in S} N_G(v)$. For a graph $G = (V, E)$ and a subset $S \subseteq V$ we denote by $E(S)$ the set of the edges of $G$ with both endpoints in $S$. For a given partition $\{A, B\}$ of $V$, we denote by $E(A, B) = \{uv \in E : u \in A, v \in B\}$. Further, $G[S]$ denotes the graph induced by $S$, defined as $G[S] = (S, E(S))$.

A triangle graph is the cycle graph $C_3$ or the complete graph $K_3$. A diamond graph has 4 vertices and 5 edges, it consists of a complete graph $K_4$ minus one edge. A graph is called cubic if all its vertices are of degree three. A graph is bipartite if its vertices can be partitioned into two sets $A$ and $B$ such that every edge connects a vertex in $A$ to one in $B$. A complete bipartite graph is a special kind of bipartite graph where every vertex of $G$ is connected to every vertex in $B$. A graph on $n$ vertices is $\delta$-dense if its minimum degree is at least $\delta n$. A set of instances is called dense if there is a constant $\delta > 0$ such that all instances in this set are $\delta$-dense (this notion was introduced in [11] and called everywhere-dense).

The density $d(G)$ of a graph $G = (V, E)$ is the ratio between the number of edges and the number of vertices in $G$, that is, $d(G) = \frac{|E|}{|V|}$. Moreover, for $S \subseteq V$, $d(S) = d(G[S]) = \frac{|E(S)|}{|S|}$.

We use $P$ to denote a partition of the set $V$ of vertices of $G$, that is, $P = \{V_1, \ldots, V_k\}$, where $\bigcup_{i=1}^{k} V_i = V$, and $V_i \cap V_j = \emptyset$ for each $i, j \in \{1, \ldots, k\}$. Then the density of a partition $P$ of $G$ is defined as $d(P) = \sum_{i=1}^{k} d(G[V_i])$, where $G[V_i]$ is the subgraph of $G$ induced by the subset $V_i$ of vertices, that is, $G[V_i] = (V_i, E_i)$, $E_i = \{\{u, v\} : \{u, v\} \in E \land u, v \in V_i\}$.

Our paper is organized as follows. Notations and formal definitions are given in Section 2. The study of (dense) bipartite graphs is established in Section 3. Section 4 presents the results on cubic graphs. In Section 5 we study dense graphs. Some conclusions are given at the end of the paper.

## 2 Preliminaries

In this paper we assume that all graphs are undirected, without loops or multiple edges, and not necessary connected. We use $G = (V, E)$ to denote an undirected graph with a set $V$ of vertices and a set $E$ of edges. We use $|V|$ to denote the number of vertices in $G$, i.e., the order of $G$, and we use $|E|$ to denote the number of edges in $G$, i.e., the size of $G$. We denote by $deg_G(v)$ the degree of $v \in V$ in $G$ that is the number of edges incident to $v$ and by $D_G(i)$ the set of vertices of degree $i$ in $G$. The maximum degree of $G$, denoted by $\Delta(G)$, is the degree of the vertex with the greatest number of edges incident to it. The minimum degree of $G$, denoted by $\delta(G)$, is the degree of the vertex with the least number of edges incident to it. For any vertex $v \in V$, $N_G(v)$ is the set of neighbors of $v$ in $G$ and $N_G(v) = N_G(v) \cup \{v\}$. Moreover, $N_G(S) = \bigcup_{v \in S} N_G(v)$. For a graph $G = (V, E)$ and a subset $S \subseteq V$ we denote by $E(S)$ the set of the edges of $G$ with both endpoints in $S$. For a given partition $\{A, B\}$ of $V$, we denote by $E(A, B) = \{uv \in E : u \in A, v \in B\}$. Further, $G[S]$ denotes the graph induced by $S$, defined as $G[S] = (S, E(S))$.

A triangle graph is the cycle graph $C_3$ or the complete graph $K_3$. A diamond graph has 4 vertices and 5 edges, it consists of a complete graph $K_4$ minus one edge. A graph is called cubic if all its vertices are of degree three. A graph is bipartite if its vertices can be partitioned into two sets $A$ and $B$ such that every edge connects a vertex in $A$ to one in $B$. A complete bipartite graph is a special kind of bipartite graph where every vertex of $A$ is connected to every vertex in $B$. A graph on $n$ vertices is $\delta$-dense if its minimum degree is at least $\delta n$. A set of instances is called dense if there is a constant $\delta > 0$ such that all instances in this set are $\delta$-dense (this notion was introduced in [11] and called everywhere-dense).

The density $d(G)$ of a graph $G = (V, E)$ is the ratio between the number of edges and the number of vertices in $G$, that is, $d(G) = \frac{|E|}{|V|}$. Moreover, for $S \subseteq V$, $d(S) = d(G[S]) = \frac{|E(S)|}{|S|}$.

We use $P$ to denote a partition of the set $V$ of vertices of $G$, that is, $P = \{V_1, \ldots, V_k\}$, where $\bigcup_{i=1}^{k} V_i = V$, and $V_i \cap V_j = \emptyset$ for each $i, j \in \{1, \ldots, k\}$. Then the density of a partition $P$ of $G$ is defined as $d(P) = \sum_{i=1}^{k} d(G[V_i])$, where $G[V_i]$ is the subgraph of $G$ induced by the subset $V_i$ of vertices, that is, $G[V_i] = (V_i, E_i)$, $E_i = \{\{u, v\} : \{u, v\} \in E \land u, v \in V_i\}$.
Dense Graph Partitioning on sparse and dense graphs

We study the problem of finding a partition $P = \{V_1, \ldots, V_k\}$ of a given graph $G$, such that $k \geq 1$ and that, among all such partitions, $d(P)$ is maximized. We refer to this problem as MAX DENSE GRAPH PARTITION and we define its decision version as follows.

**DENSE GRAPH PARTITION**

**Input:** An undirected graph $G = (V, E)$, a positive rational number $r$.

**Question:** Is there a partition $P$ such that $d(P) \geq r$?

Given an optimization problem in NPO and an instance $I$ of this problem, we denote by $|I|$ the size of $I$, by $\text{opt}(I)$ the optimum value of $I$, and by $\text{val}(I, S)$ the value of a feasible solution $S$ of instance $I$. The performance ratio of $S$ (or approximation factor) is $r(I, S) = \max\left\{\frac{\text{val}(I, S)}{\text{opt}(I)} : \text{val}(I, S) \geq \frac{1}{I}\right\} \geq 1$. For a function $f$, an algorithm is an $f(|I|)$-approximation, if for every instance $I$ of the problem, it returns a solution $S$ such that $r(I, S) \leq f(|I|)$. Moreover if the algorithm runs in polynomial time in $|I|$, then this algorithm gives a polynomial-time $f(|I|)$-approximation. We consider in this paper only polynomial time algorithms. When $f$ is a constant $\alpha$, the problem is polynomial-time $\alpha$-approximable. When $f = 1 + \varepsilon$, for any $\varepsilon > 0$, the problem admits a polynomial-time approximation scheme. When the running time of an approximation scheme is of the form $O(g(1/\varepsilon)\text{poly}(|I|))$ the problem has an efficient polynomial-time approximation scheme (eptas).

Before we start studying specific graph classes, we observe the following helpful structural properties that hold for DENSE GRAPH PARTITION on general graphs.

**Remark 1.** We can assume that for any optimal partition $P$ and for any part $P_i \in P$, $G[P_i]$ is connected, since otherwise turning each connected component into its own part does not decrease the density.

When discussing the density of a (sub)graph, it is often useful to think about how close this subgraph is to being a clique. We therefore call a pair of non-adjacent vertices in a (sub)graph a missing edge, and use the number of such missing edges to estimate the density of the (sub)graph. With such estimations, it is easy to show that the following intuition about fearing complete graphs as communities.

**Lemma 2.** Among all partitions of $G$ into $t \geq 2$ parts, those where the parts correspond to complete graphs, if there exists such, have the largest density.

**Proof.** Consider a partition of $G$ into $t$ parts $\{V_1, \ldots, V_t\}$ of size $n_1, \ldots, n_t$. If $G[V_i]$ has $o_i$ missing edges for any $1 \leq i \leq t$, then the density of this partition is $\frac{n_i + 1}{n_i} - \frac{o_i}{n_i} - \ldots - \frac{o_t}{n_t}$.

Consider a partition of $G$ into $t$ parts of size $n'_1, \ldots, n'_t$ such that each part induces a complete graph for any $1 \leq i \leq t$. Then the density of this partition is $\frac{n'_i}{t}$ and thus it is larger than the density of any partition in $t$ parts where at least one edge is missing inside $G[V_i]$ for some $1 \leq i \leq t$.

A direct consequence of this is the following.

**Lemma 3.** Let $G = (V, E)$ be a graph and $P$ be any partition of $V$. Then $d(P) \leq \frac{|V|}{2} - \frac{|P|}{2}$.

### 3 Dense Bipartite Graphs

In this section we show that MAX DENSE GRAPH PARTITION has a trivial solution on complete bipartite graphs. Moreover, using this result we show that the problem is NP-hard on dense bipartite graphs.

In the first part, we consider a complete bipartite graph $G_{n,m}$ with the two subsets that are independent sets of size $n$ and $m$ and we first prove the following result.
Lemma 4. The density \( d(G_{n,m}) \) of a complete bipartite graph \( G_{n,m} \) is greater than or equal to the density \( d(\mathcal{P}) \) of any partition \( \mathcal{P} \) of \( G_{n,m} \).

Proof. The density of the complete bipartite graph \( G_{n,m} = (A, B, E) \), with \( |A| = n, |B| = m \) is given by \( d(G_{n,m}) = \frac{nm}{n+m} \).

It suffices to show that \( d(G_{n,m}) \) is greater than or equal to the density of any partition \( \mathcal{P} = \{V_1, V_2\} \) that splits the set of vertices into exactly 2 nonempty subsets. Indeed, if this holds and we have a partition \( \mathcal{P} = \{V_1, \ldots, V_k\} \) where \( k \geq 3 \), we can show recursively that \( d(G_{n,m}) \geq d(G[V_1]) + d(G[V_2 \cup \cdots \cup V_k]) \geq \cdots \geq d(G[V_1]) + \cdots + d(G[V_k]) \).

We first consider a partition \( \mathcal{P}_1 = \{V_1, V_2\} \) where \( A \subseteq V_1 \). Without loss of generality we may assume that \( V_2 = B \setminus V_1 \) contains \( m_2 \) vertices from \( B \). Then

\[
d(\mathcal{P}_1) = \frac{n(m - m_2)}{n + m - m_2} + 0 \leq \frac{nm}{n+m}
\]

Now, consider a partition \( \mathcal{P}_1 = \{V_1, V_2\} \) such that each of the graphs \( G[V_i] \) contains at least one edge, so let \( G[V_i] = G_{n_i,m_i} \) with \( 0 < n_1 < n \) and \( 0 < m_1 < m \). Then \( G[V_2] = G_{n-n_1,m-m_1} \) and

\[
d(\mathcal{P}_1) = \frac{n_1 m_1}{n_1 + m_1} + \frac{(n - n_1)(m - m_1)}{n + m - n_1 - m_1} = \frac{nm(n_1 + m_1) - mn_1^2 - mn_1^2}{(n + m - n_1 - m_1)(n_1 + m_1)},
\]

which yields

\[
d(G_{n,m}) - d(\mathcal{P}_1) = \frac{(nm_1 - mn_1)^2}{(n + m - n_1 - m_1)(n_1 + m_1)(n + m)} \geq 0
\]

It follows that an optimal solution of any complete bipartite graph is the whole graph. From the calculations in the previous proof, we can inductively deduce the following result.

Corollary 5. For any complete bipartite graph \( G = (A, B, E) \) with \( |A| = n \) and \( |B| = m \), a partition \( \mathcal{P} = \{V_1, \ldots, V_k\} \) of \( A \cup B \) satisfies \( d(\mathcal{P}) = \frac{nm}{n+m} \) if and only if \( G[V_i] = G_{n_i,m_i} \), with \( n_1 \neq 0 \) and \( m_i \neq 0 \) and \( \frac{n_1}{m_1} = \frac{n}{m} \) for all \( i \in \{1, \ldots, k\} \).

Consequently, for any complete bipartite graph \( G_{n,m} \), if \( n \) and \( m \) are relatively prime the only optimal solution of \( G_{n,m} \) is the whole graph. Otherwise, several optimal solutions exist and are characterized exactly by Corollary 5

Theorem 6. Dense Graph Partitioning is NP-hard on dense bipartite graphs.

Proof. We give a reduction from Dominating Set. Let \( G = (V, E) \) with \( V = \{v_1, \ldots, v_n\} \) and an integer \( k \geq 1 \) be an instance of Dominating Set. Assume without loss of generality that \( G \) is connected. We first construct a bipartite graph \( G' = (V_1, V_2, E') \), that is not dense, and show how solving Dense Graph Partitioning on it solves Dominating Set on \( G \). In a second step, we show how to make \( G' \) dense maintaining the reduction.

We construct \( G' = (V_1, V_2, E') \) as follows:

- \( V_1 = V \cup \{v_i : 1 \leq i \leq n - k, 1 \leq j \leq k\} \cup \{z\} \)
- \( V_2 = V' \cup \{x_i : 1 \leq i \leq n, 1 \leq j \leq k\} \cup \{z_i : 1 \leq i \leq N - n\} \) where \( V' = \{v'_1, \ldots, v'_n\} \) and \( N \in \mathbb{N} \) is chosen as follows. Let \( c \in \mathbb{N} \) be the smallest integer such that \( c(n-k+1) - 1 > n \) (note that \( 1 \leq c \leq n \) and define \( N = c(n-k+1) - 1 \). For this choice of \( N \) it follows that the greatest common divisor of \( N \) and \( n-k+1 \) is 1, and \( n < N \leq 2n \).
Figure 1 A graph $G$, instance of DOMINATING SET and the bipartite graph $G'$ obtained from $G$, for $k = 2$ and $n = 5$.

$E' = E_d \cup E_w \cup E_v \cup E_z$ with

$E_d = \{\{v_i, v_j\} : \{v_i, v_j\} \in E\} \cup \{\{v_i, v'_j\} : 1 \leq i \leq n\}$,

$E_w = \{\{w_{j}^i, w_{j}^{i+1}\} : 1 \leq i \leq n - k, 1 \leq r \leq N - 1, 1 \leq j \leq k\}$,

$E_v = \{\{v, v'_j\} : 1 \leq i \leq n - k, 1 \leq j \leq k, 1 \leq s \leq n\} \cup \{\{v_i, x_{j}^i\} : 1 \leq s \leq n, 1 \leq r \leq N, 1 \leq j \leq k\}$ and

$E_z = \{\{z, z_j\} : 1 \leq j \leq N - n\} \cup \{\{z, x_{j}^i\} : 2 \leq r \leq N, 1 \leq j \leq k\} \cup \{\{v_i, z_j\} : 1 \leq i \leq n, 1 \leq j \leq N - n\}$

Notice that $G'$ is a bipartite graph with $|V_1| = n + 1 + k(n - k)$ and $|V_2| = (k + 1)N$.

We show that there exists a dominating set of cardinality at most $k$ in $G$ if and only if there exists a partition $\mathcal{P}$ of $G'$ with $d(\mathcal{P}) = (k + 1)d(G_{n-k+1,N})$.

Suppose there exists a dominating set $D$ in $G$ with $|D| = k$. Let $D = \{v_{i_1}, \ldots, v_{i_k}\}$ and $N'(v_{i_j}) = N_G(v_{i_j}) \setminus (D \cup N_G(\{v_{i_1}, \ldots, v_{i_{j-1}}\})$. Define the partition $\mathcal{P} = \{P_1, \ldots, P_{k+1}\}$ by:

$P_j = \{v_{i_j}\} \cup \{v'_j : v_j \in N'(v_{i_j})\} \cup \{w_{j}^i : 1 \leq i \leq n - k\} \cup \{x_{j}^i : 1 \leq r \leq N - |N'(v_{i_j})|\}$ for $1 \leq j \leq k$ and $P_{k+1} = V_1 \cup V_2 \setminus (\cup_{j=1}^{k} P_j)$. With this definition, $\mathcal{P}$ is clearly a partition of $V_1 \cup V_2$, and each partition $P_j$ contains $n - k + 1$ vertices from $V_1$ and $N$ vertices from $V_2$ for each $1 \leq j \leq k + 1$. Further, each $P_j$ induces a complete bipartite graph $G_{n-k+1,N}$: all vertices $w_{j}^i$ and $x_{j}^i$ are connected to each other, and to all vertices in $V_2$ and $V_1$, respectively, by construction. Further, $v_{i_j}$ is connected in $G'$ to all vertices in $N'(v_{i_j})$; note here that in $G'$ we connected $v_i$ to its “copy” $v'_i$ for all $1 \leq i \leq n$, which models the case that $v_{i_j}$ dominates itself. For $P_{k+1}$, note that $z$ is adjacent to all $x_{j}^i$-vertices, and each $z_j$ is adjacent to all vertices in $V$. Since $D$ is a dominating set, each vertex from $V'$ is contained in some $N'(v_{i_j})$, thus $V_2 \setminus (\cup_{j=1}^{k} P_j)$ only contains $x_{j}^i$-vertices. Also, the $P_j$ contain all $w_{j}^i$-vertices and hence $V_1 \setminus (\cup_{j=1}^{k} P_j)$ only contains vertices from $V$.

Conversely, let $\mathcal{P}$ be a partition of $G'$ of density $(k + 1)d(G_{n-k+1,N})$. Thus, Corollary 5 implies that the vertices for each set $P \in \mathcal{P}$ induce a complete bipartite graph $G_{r,s}$ such that

$\frac{r}{s} = \frac{|V_1|}{|V_2|} = \frac{\frac{(n-k)n+1}{N}}{\frac{(k+1)n-N}{N}} = \frac{n-k+1}{N}$. Since the greatest common divisor of $n - k + 1$ and $N$ is one, this yields $r \geq n - k + 1$ and $s \geq N$ and especially $\mathcal{P}$ can contain at most $k + 1$ sets.

For all $w_{j}^i$ and $w_{j}^{i+1}$, if $j \neq t$, $w_{j}^i$ and $w_{j}^{i+1}$ have $n$ common neighbors, and since $n < N$ there is no part $P \in \mathcal{P}$ such that $w_{j}^i, w_{j}^{i+1} \in P$. Moreover, for all $i, j, w_{j}^i$ and $z$ have $N - 1$ common neighbors so they also cannot be in the same $P \in \mathcal{P}$. Hence, there are exactly $k + 1$ parts in $\mathcal{P}$ that are complete bipartite graphs $G_{n-k+1,N}$.

For all $1 \leq j \leq k$, denote by $P_j$ the set containing the vertices $w_{j}^i$ for all $1 \leq i \leq n - k$ and $P_z$ the set containing $z$. To reach cardinality exactly $n - k + 1$, $P_j \cap V_1$ has to contain
Let $G = (V,E)$ be a cubic graph without connected components that induce a $K_4$. For any partition $\mathcal{P}$ of $G$ the following holds:

\[ u_P(v) \leq \frac{1}{4} \text{ for all vertices } v \in V \]

\[ \text{if } P \text{ is not a triangle, diamond or Case 1 in Figure 2 then } u(P) \leq \frac{1}{4} \]

**Proof.** Let $\mathcal{P}$ be a partition of $G$, $P \subseteq \mathcal{P}$ and $v \in P$. Since $G$ is cubic, $d(P) \leq \frac{3|P|}{2|E|} = \frac{3}{2}$. Then $u_P(v) \leq \frac{3}{2|E|}$. If $|P| \geq 6$, $u_P(v) \leq \frac{3}{2|E|} = \frac{1}{4}$. For $|P| = 5$ it follows that $u_P(v) \leq \frac{7}{25} < \frac{1}{4}$, since a cubic graph on 5 vertices cannot have more than 7 edges. Also, since there exists no $K_4$ in $G$, the only graph on 5 vertices with 7 edges is Case 1 in Figure 2 and all other graphs on 5 vertices have 6 or less edges which yields a utility of at most $\frac{7}{25} < \frac{1}{4}$.

Case analysis on the graphs of size 4 or less yields that the largest utility is achieved for $P$ being a triangle, which gives $u_P(v) = \frac{1}{3}$. Further, if $P$ is not a triangle or a diamond,
Dense Graph Partitioning on sparse and dense graphs

case analysis on the graphs of size 4 or less shows that $u_P(v)$ is maximized when $P$ is an induced matching and its value is $\frac{1}{4}$.

\begin{itemize}
  \item Lemma 9. Let $G$ be a cubic graph without connected components that induce a $K_4$, and let $v_1, v_2, v_3, v_4$ be vertices in $G$ that induce a diamond. Then $u_P(v_1) + u_P(v_2) + u_P(v_3) + u_P(v_4) \leq \frac{5}{4}$ for any partition $P$ for $G$.

  \begin{proof}
    Let $P$ be any partition of $G$. Let $P_1 \in P$ (resp. $P_2$, $P_3$ and $P_4$) be the part that contains $v_1$ (resp. $v_2$, $v_3$ and $v_4$). We distinguish several cases.

    \textbf{Case 1:} The four vertices $v_i$ are in the same part $P_1$. If $P_1$ is a diamond, then $d(P_1) = \frac{5}{4}$ and thus $u_P(v_1) + u_P(v_2) + u_P(v_3) + u_P(v_4) = \frac{5}{4}$. If the four vertices are in a part $P_1$ with more than 4 vertices, by Lemma 8 the only subgraph that gives utility more than $\frac{1}{4}$ per vertex is the graph displayed as Case 1 in Figure 2. This graph yields a utility of $\frac{7}{24}$ which gives $u_P(v_1) + u_P(v_2) + u_P(v_3) + u_P(v_4) = \frac{28}{24} < \frac{5}{4}$.

    \textbf{Case 2:} Three among the four vertices of the diamond are in the same part. Then the fourth vertex has degree at most one in its part, thus by Lemma 8 its utility is at most $\frac{1}{4}$. Further, also by Lemma 8 the utility of the other three vertices is at most $\frac{1}{4}$ and we conclude that $u_P(v_1) + u_P(v_2) + u_P(v_3) + u_P(v_4) \leq 1 + \frac{1}{4} = \frac{5}{4}$.

    \textbf{Case 3:} At most two of the four vertices are together in the same part. Then the two vertices of degree three in the diamond have degree at most one in their part, thus by Lemma 8 we deduce like in Case 2 that $u_P(v_1) + u_P(v_2) + u_P(v_3) + u_P(v_4) \leq 2 \frac{1}{4} + 2 \frac{1}{4} < \frac{5}{4}$.

  \end{proof}

  \end{itemize}

\begin{itemize}
  \item Lemma 10. Let $G$ be a cubic graph on $n$ vertices without connected components that induce a $K_4$, and let $D$ be the set of diamonds in $G$ and $T$ the set of triangles in $G$ that do not belong to a diamond. For any partition $P$, $d(P) \leq \frac{5}{4}|D| + |T| + \frac{1}{4}(n - 3|T| - 4|D|)$.

  \begin{proof}
    By Lemma 8 the only vertices with utility more than $\frac{1}{4}$ are those that are in triangles, diamonds, or the unique neighbors of diamonds (in the sense of vertex $v_5$ in Case 1 of Figure 2) and we know that the sum of the utilities of the vertices constituting a triangle is at most $3 \cdot \frac{1}{4} = 1$. By Lemma 9 we further know that the sum of the utilities of the vertices constituting a diamond is at most $\frac{5}{4}$. The unique neighbors of diamonds have a utility of more than $\frac{1}{4}$ if and only if they are in a part isomorphic to Case 1 of Figure 2 which has a density of $\frac{7}{24} < \frac{5}{4} + \frac{1}{4}$. Thus, if $S$ is the set of unique neighbors of diamonds, then the sum of the utilities of the vertices in the diamonds in $D$ and the vertices in $S$ is at most $\frac{5}{4}|D| + \frac{1}{4}|S|$. All remaining vertices have a utility of at most $\frac{1}{4}$ by Lemma 8. We deduce that $d(G) \leq \frac{5}{4}|D| + \frac{1}{4}|S| + |T| + \frac{1}{4}(n - 3|T| - 4|D| - |S|) = \frac{5}{4}|D| + |T| + \frac{1}{4}(n - 3|T| - 4|D|)$.
  \end{proof}

\end{itemize}

\caption{Different cases of Lemma 9}
\end{figure}
We show that Dense Graph Partition is NP-complete even for cubic graphs by giving a reduction from Exact Cover By 3-Sets where each element appears in exactly 3 sets, denoted Restricted Exact Cover By 3-Sets, known to be NP-hard by [13].

Restricted Exact Cover By 3-Sets (RX3C)

**Input:** A set \( X \) of elements with \( |X| = 3q \) and a collection \( C \) of 3-element subsets of \( X \), where each element appears in exactly 3 sets.

**Question:** Does \( C \) contain an exact cover for \( X \), i.e. a subcollection \( C' \subseteq C \) such that every element occurs in exactly one member of \( C' \)?

The following definition gives the construction to reduce RX3C to Dense Graph Partition.

**Definition 11.** Let \( I = (X,C) \) be an instance of RX3C. We define the construction \( \sigma \) transforming the instance \( I \) into the graph \( G := \sigma(I) \) where \( G = (V,E) \) is build as follows (see Figures 3 and 4):

- for each element \( x \in X \), add the vertex \( v_x \) to \( V \) (called vertices of type 1 or black vertices).
- for each subset of the collection \( \{x,y,z\} \in C \), add the vertices \( v^x_{xyz}, v^y_{xyz}, v^z_{xyz} \) to \( V \) (called vertices of type 2 or white vertices).
- add the edges \( \{v^x_{xyz}, v^y_{xyz}, v^z_{xyz}\} \) and \( \{v^y_{xyz}, v^z_{xyz}\} \) to \( E \)
- add the edges \( \{v^x_{xyz}, v_x\}, \{v^y_{xyz}, v_y\} \) and \( \{v^z_{xyz}, v_z\} \) to \( E \)

Notice that \( G \) is a cubic graph on \(|X|\) vertices of type 1 and \( 3|X| \) vertices of type 2.

Case distinction on the subgraphs in \( \sigma(I) \) shows:

**Lemma 12.** For \( G = (V,E) = \sigma(I) \) and any \( P \subseteq V \), it holds that \( u(P) \geq \frac{1}{4} \) if and only if \( G[P] \) is isomorphic to one of the following three graphs:

- a triangle where all the vertices are of type 2 and then \( u(P) = \frac{1}{4} \).
- an edge between two type 2 vertices or between two vertices of different types and then \( u(P) = \frac{1}{4} \).
- the subgraph described in Figure 4 and then \( u(P) = \frac{1}{4} \).

**Proof.** Let \( P \subseteq V \) such that \( u(P) \geq \frac{1}{4} \). We show in the following that there are exactly three possible subgraphs \( G[P] \) such that \( u(P) \geq \frac{1}{4} \). \( G \) obviously does not contain a connected component that is a \( K_4 \). Also, observe that by its construction, \( G \) does not contain \( C_4 \) as subgraph, since there are no two vertices \( u,v \in V \) that have more than one common neighbor. Note that this also implies that \( G \) is diamond-free.

As \( G \) is cubic, \( |E(G[P])| \leq \frac{2}{3}|P| \) and so \( d(P) \leq \frac{2}{3}|P| \cdot \frac{1}{|P|} = \frac{2}{3} \). Since \( \frac{1}{4} \leq u(P) \leq \frac{m}{2|P|} \) then \( |P| \leq 6 \). We study the five following cases:
Dense Graph Partitioning on sparse and dense graphs

- Case $|P| = 6$: Since $u(P) = \frac{|E(P)|}{d} \geq \frac{1}{2}$, we have $|E(P)| \geq 9$. Since $G[P]$ cannot be cubic (G is connected and $|V| > 6$), a subgraph with $|P| = 6$ and $|E(P)| \geq 9$ does not exist.
- Case $|P| = 5$: Since $u(P) = \frac{|E(P)|}{d} \geq \frac{1}{4}$, we have $|E(P)| \geq 7$. Since $G$ contains no $K_4$, the only possibility for this is the graph displayed as Case 1 in Figure 2. Since $G$ is also diamond-free, such a subgraph does not exist.
- Case $|P| = 4$: Since $u(P) = \frac{|E(P)|}{d} \geq \frac{1}{4}$, we have $|E(P)| \geq 4$. Since $G$ does not contain a $C_4$ the only possibility for $G[P]$ is the subgraph described in Figure 3.
- Case $|P| = 3$: Since $u(P) = \frac{|E(P)|}{d} \geq \frac{1}{4}$, we have $|E(P)| \geq 3$ and thus $P$ is a triangle where all the vertices are of type 2 and $u(P) = \frac{3}{4}$.
- Case $|P| = 2$: Since $u(P) = \frac{|E(P)|}{d} \geq \frac{1}{4}$, we have $|E(P)| \geq 1$ and thus $S$ is an edge between two type 2 vertices or between two vertices of different types and $u(P) = \frac{1}{4}$.

\[\text{Remark 13.}\] The case-analysis in the proof of Lemma 12 also shows that for any subset $P \subseteq V$ of the vertices of the graph $\sigma(I)$, if $v$ is of type 2 then $u_S(v) \leq \frac{1}{4}$, otherwise $u_S(v) \leq \frac{1}{2}$.

With these observations about the construction of $\sigma(I)$, we are able to prove our NP-completeness result.

**Theorem 14.** Dense Graph Partition is NP-complete on cubic graphs.

**Proof.** Let $I = (X, C)$ be an instance of RX3C. We claim that $I = (X, C)$ is a yes-instance of RX3C if and only if $I' = (G, d)$ with $G = \sigma(I)$ and $d = \frac{7|X|}{6}$ is a yes-instance of Dense Graph Partition.

Let $C' \subseteq C$ be an exact cover for $X$ of size $\frac{|X|}{3}$. Consider the following partition $\mathcal{P}$ with $\frac{2|X|}{3}$ parts: for any $c \in C'$, $c = \{x, y, z\}$, we define three parts of size 2, $\{v_x, v^x_{yz}\}$, $\{v_y, v^y_{xz}\}$, $\{v_z, v^z_{xy}\}$ and for any $c \notin C'$, $c = \{x, y, z\}$, we define the following part of size 3, $\{v^x_{xyz}, v^y_{xyz}, v^z_{xyz}\}$. Since $C'$ is an exact cover, $\mathcal{P}$ is a partition for $G$ and its density is $\frac{3}{2} \cdot \frac{|X|}{3} + \frac{2}{3}|X| = \frac{5}{6}|X|$.

Let $\mathcal{P}'$ be a partition of $G$ of density $d(\mathcal{P}') = \frac{7}{6}|X|$. Firstly, we show that $\mathcal{P}'$ has necessarily the following shape: $\frac{2|X|}{3}$ parts of size 3 containing only vertices of type 2 forming a triangle in $G$ and $|X|$ parts of size 2 containing one vertex of type 1 and one of type 2 adjacent in $G$ (see Figures 3 and 4). From Remark 1 we can assume that all parts induce connected subgraphs.

We first show that $d(\mathcal{P}') = \frac{7}{6}|X|$ implies that there are at least $\frac{2|X|}{3}$ parts in $\mathcal{P}'$ corresponding to triangles in $G$. Assume by contradiction that $\mathcal{P}'$ has $\frac{2}{3}|X| - \ell$ triangles, with $\ell > 0$. Since $G$ has $4|X|$ vertices, there are $2|X| + 3\ell$ vertices that do not belong to a part in $\mathcal{P}'$ that corresponds to a triangle in $G$. By Lemma 12 the utility of these last vertices is smaller than or equal to $\frac{1}{4}$. Then the density of $\mathcal{P}'$ is

$$d(\mathcal{P}') \leq \frac{2}{3}|X| - \ell + (2|X| + 3\ell) \cdot \frac{1}{4} = \frac{7}{6}|X| - \frac{\ell}{4} \leq \frac{7}{6}|X|$$

This contradicts the choice of $\mathcal{P}'$ such that $d(\mathcal{P}') = \frac{7}{6}|X|$, hence there are at least $\frac{2}{3}|X|$ triangles in $\mathcal{P}'$.

Now, we will prove that there are at most $\frac{2}{3}|X|$ parts in $\mathcal{P}'$ corresponding to triangles in $G$. Assume by contradiction that $\mathcal{P}'$ has $\frac{2}{3}|X| + \ell$ triangles, with $\ell > 0$. Since there are $3|X|$ vertices of type 2 and among these vertices $3 \cdot (\frac{2}{3}|X| + \ell)$ belong to a triangle then $|X| - 3\ell$ vertices of type 2 do not belong to a triangle. Each neighbor of a vertex $v_z$ of type 1 is of type 2, so if the utility of $v_z$ is positive, then there exists a vertex of type 2, $v^x_{xyz}$, neighbor
of \(v_x\), that is in the same part as \(v_x\) and \(v_{xyz}^{xy}\) does not belong to a triangle. Moreover, as all type 1 vertices have no common neighbors, for each type 1 vertex with positive utility, there is a type 2 vertex that is not in a triangle. Since there are at most \(|X| - 3\ell\) type 2 vertices that do not belong to a triangle, there are at most \(|X| - 3\ell\) type 1 vertices with positive utility. Then the density of \(P'\) is at most

\[
d(P') \leq \frac{2|X|}{3} + \ell + \frac{|X| - 3\ell}{4} + \frac{|X| - 3\ell}{4} \leq \frac{7|X|}{6} - \frac{\ell}{2} < \frac{7|X|}{6}.
\]

This contradicts the choice of \(P'\) such that \(d(P') = \frac{7|X|}{6}\), and then there are exactly \(\frac{2|X|}{3}\) triangles in \(P'\).

We will show now that \(d(P') = \frac{7|X|}{6}\) implies that all type 1 vertices are in a part that is a matching with a type 2 vertex. There are \(|X|\) type 1 vertices and \(|X|\) type 2 vertices that are not in some triangle in \(P'\). Since there are exactly \(\frac{2|X|}{3}\) parts in \(P'\) forming a triangle and the utility of each other vertex is smaller than or equal to \(\frac{1}{4}\), to reach a density of \(\frac{7|X|}{6}\) it is necessary that each of the \(2|X|\) vertices outside the parts that are triangles has a utility of exactly \(\frac{1}{4}\). To reach this utility, by Lemma 12 there are two possibilities, the graph described in Figure 4 and an edge. Since there are exactly \(|X|\) vertices of type 1 and \(|X|\) vertices of type 2 outside the triangles in \(P'\), and vertices of type 1 only have neighbors of type 2, the only possibility for all these vertices to have utility \(\frac{1}{4}\) is if each type 1 vertex is matched with one type 2 vertex.

Consider now the following subcollection \(C'' \subseteq C\): for each triple \(v_{xyz}^{xy}, v_{xyz}^{yz}, v_{xyz}^{zx}\) that does not belong to a triangle, we add the set \(\{x, y, z\}\) to \(C''\). The subcollection \(C''\) is a cover since each type 1 vertex is a neighbor of one of these vertices and it is an exact cover since there are exactly \(\frac{|X|}{3}\) 3-element subsets that do not belong to a triangle.

Our observations about the maximum utility of certain vertices can also be used to show the following positive result.

**Theorem 15.** **Max Dense Graph Partition** is polynomial-time \(\frac{4}{3}\)-approximable on cubic graphs.

**Proof.** Let \(I = G\) be a cubic graph, instance of Max Dense Graph Partition. If \(G\) contains connected components isomorphic to \(K_4\), create a part for each such component, as this is the optimum way to partition these sets. So assume that \(G\) contains no connected component isomorphic to \(K_4\), and let \(D\) be the set of all diamonds in \(G\), and \(T\) the set of all triangles that do not belong to a diamond. Diamonds (resp. triangles) can be found in polynomial time simply by enumerating all 4-tuples (resp. 3-tuples) of vertices and checking if they induce a diamond (resp. triangle) as subgraph. Let \(G'\) be the graph obtained from \(G\) after removing the vertices of \(D\) and \(T\). Let \(M\) be the set of edges that constitute a maximum matching of \(G'\). Let \(G''\) be the graph obtained from \(G'\) after removing the vertices of \(M\). Since \(M\) is a maximal matching, the vertices in \(G''\) form an independent set.

We show in the following that \(|V(G'')| \leq \frac{|V(G)|}{4}\).

For each \(v \in V\) we associate a function \(t(v)\) and initialize it with \(t(v) = 1\). When removing the diamonds and triangles from \(G\) in order to get \(G''\) we update the function \(t\) as follows:

- For every diamond \(\{u_1, u_2, u_3, u_4\} \subseteq V\) that is deleted from \(V\), let \(u_1\) and \(u_3\) be the vertices with neighbors outside of the diamond (if these vertices still exist) and let \(v_1\) and \(v_3\) be those neighbors (with the possibility that \(v_1 = v_3\)). We update the function \(t: t(v_1) := t(v_1) + t(u_1) + t(u_2)\) and \(t(v_3) := t(v_3) + t(u_3) + t(u_4)\) (thus
Dense Graph Partitioning on sparse and dense graphs

\( t(v_1) := t(v_1) + t(u_1) + t(u_2) + t(u_3) + t(u_4) \) if \( v_1 = v_3 \). If \( v_1 \) or \( v_3 \) were already deleted, we delete their associated \( t \) function.

For every triangle \( \{u_1, u_2, u_3\} \subseteq V \) that is deleted from \( V \), let \( v_1 \) (resp. \( v_2 \) and \( v_3 \)) be the neighbor of \( u_3 \) (resp. \( u_2 \) and \( u_3 \)) outside of the triangle (if these vertices exist). We update the function \( t : t(v_1) := t(v_1) + t(u_1), t(v_2) := t(v_2) + t(u_2) \) and \( t(v_3) = t(v_3) + t(u_3) \). If \( v_1, v_2 \) or \( v_3 \) do not exist, we delete their associated \( t \) function.

Observe that after updating \( t \) for any \( v \in V(G') \), if \( v \in D_{G'}(3) \) then \( t(v) \geq 1 \), if \( v \in D_{G'}(2) \) then \( t(v) \geq 2 \), if \( v \in D_{G'}(1) \) then \( t(v) \geq 3 \) and if \( v \in D_{G'}(0) \) then \( t(v) \geq 4 \). In order to justify this, observe that the \( t \) function associated to vertices in \( V(G') \) cannot decrease. If a vertex \( v \) is of degree \( 3 - i \) in \( G' \), \( 1 \leq i \leq 3 \), then there are at least \( i \) adjacent edges to distinct vertices in triangles or diamonds that were removed from \( G \) and increase \( t(v) \). Each time when a neighbor of a vertex \( v \) from a diamond or a triangle is removed then \( t(v) \) increases by at least one. Then, in \( G' \), each vertex \( v \) of degree \( 3 - i \) has \( t(v) \geq i + 1 \).

Let \( n'_i \) be the number of vertices of degree \( i \) in \( G' \). By the previous remark, we have

\[
\sum_{v \in V(G')} t(v_i) \geq 4n'_0 + 3n'_1 + 2n'_2 + n'_3 \tag{1}
\]

Since \( G' \) is a subcubic triangle-free graph and \( M \) a maximum matching in \( G' \), using a result of Munaro [16], we get

\[
|V(M)| \geq \frac{9}{10}n'_0 + \frac{3}{5}n'_1 + \frac{3}{10}n'_4 \tag{2}
\]

We show now that \( 4|V(G'')| \leq \sum_{v \in V(G')} t(v_i) \). In fact, combining \( |V(G'')| = n'_0 + n'_1 + n'_2 + n'_3 \) with inequality (2) gives \( |V(G'')| \leq n'_0 + \frac{7}{10}n'_1 + \frac{2}{5}n'_2 + \frac{1}{10}n'_4 \). Thus, \( 4|V(G'')| \leq 4n'_0 + \frac{28}{10}n'_1 + \frac{8}{5}n'_2 + \frac{4}{10}n'_3 \leq 4n'_0 + 3n'_1 + 2n'_2 + n'_3 \leq \sum_{v \in V(G')} t(v_i) \) using inequality (1). Then

\[
4|V(G'')| \leq \sum_{v \in V(G')} t(v_i) \quad \text{and since} \quad |V(G)| \geq \sum_{v \in V(G')} t(v_i) \quad \text{we get} \quad |V(G'')| \leq \frac{4}{5}|V(G)|.
\]

Consider the partition \( \mathcal{P} = D \cup T \cup M \cup V(G') \) in the sense that \( \mathcal{P} \) contains a set for each diamond in \( D \), one set for each triangle in \( T \), one set for each edge in the matching \( M \) and one set for each vertex in \( V(G') \). Then \( d(\mathcal{P}) = \frac{1}{2}|D| + \frac{1}{2}|T| + \frac{1}{2}|M| \geq \frac{1}{2}|D| + \frac{1}{2}|T| + \frac{1}{2}|(n-3)|T| - 4|D| - \frac{2}{3} \) since \( |V(G'')| \leq \frac{4}{5}|V(G)| \). By Lemma 10 we know that \( \text{opt}(I) \leq \frac{4}{3}|D| + \frac{1}{3}|T| + \frac{1}{3} \left( (n-3)|T| - 4|D| \right) \). Then \( \text{opt}(I) d(\mathcal{P}) \leq \frac{1}{2}|D| + \frac{1}{2}|T| + \frac{1}{2} \left( (n-3)|T| - 4|D| \right) + \frac{2}{3} \left( (n-3)|T| - 4|D| \right) = \frac{4}{3}|D| + \frac{1}{3}|T| + \frac{2}{3} = 1 + \frac{n}{4|D| + 4|T| + 3n} \leq 1 + \frac{1}{3} \).

Then \( \frac{\text{opt}(I)}{d(\mathcal{P})} \leq \frac{4}{3}. \)

5 Dense Graphs

In this section we consider graphs \( G = (V, E) \) on \( n \) vertices such that \( G \) can be viewed as \( G = \overline{H} \) where \( H \) is a graph of small maximum degree. Note that the edges of \( H \) are exactly the missing edges of \( G \). We first consider graphs \( G = (V, E) \) on \( n \) vertices such that \( \delta(G) \geq n - 3 \), that is \( G = \overline{H} \) where \( H \) has \( \Delta(H) = 2 \) and has \( q \leq n \) edges and show that MAX DENSE GRAPH PARTITION is solvable in polynomial time on these graphs.

\( \blacktriangleright \textbf{Lemma 16.} \) For any graph \( G \) on \( n \) vertices such that \( \delta(G) \geq n - 3 \), its density \( d(G) \) is greater than or equal to the density of any partition \( \mathcal{P} \) of \( G \) into \( t \geq 3 \) parts.

\( \textbf{Proof.} \) The density of \( G \) is given by \( d(G) = \frac{n(n-1) - \delta(G)}{n} = \frac{n - \delta(G)}{2} = \frac{n - 2}{2} \). From Lemma 2 among all partitions of \( G \) into \( t \geq 3 \) parts, those where the parts correspond to complete graphs...
have the largest density. The density of such a partition into $t$ parts of size $n_1, \ldots, n_t$ is $\frac{n-1}{2}$. Thus, the density of $G$ is at least as large as the density of this last partition since $t \geq 3$ and $q \leq n$ (note here that a graph with minimum degree $n-3$ has at most $n$ missing edges).

Observe that in the proof of the previous lemma when $q = n$ and $t = 3$, the density of a partition in $3$ parts corresponding to complete subgraphs and the density of the entire graph are the same. This previous lemma implies that for any graph $G$ such that $\delta(G) \geq n-3$, there exists a partition into one or two parts of maximum density.

**Lemma 17.** For any graph $G$ on $n$ vertices such that $\delta(G) \geq n-3$, in any partition for $G$ into two parts, the sum of missing edges in the two parts is at least $o$, where $o$ is the number of odd cycles in $G$.

**Proof.** Let $C$ be an odd cycle in $\overline{G}$ (the graph of missing edges in $G$). Since $C$ is not bipartite, there is no partition $\{V_1, V_2\}$ of $V$ such that all the edges of $C$ have one endpoint in $V_1$ and one endpoint in $V_2$. Hence, for any partition $\{V_1, V_2\}$ at least one of the missing edges from $C$ is inside $G[V_1] \cup G[V_2]$.

**Lemma 18.** Among all partitions into $2$ parts of fixed size containing $x$ missing edges, the one containing all missing edges in the largest part has the best density.

**Proof.** Consider two partitions $\{V_1, V_2\}$ and $\{V'_1, V'_2\}$ such that $|V_1| = |V'_1| = n_1$ and $|V_2| = |V'_2| = n_2$ with $n_1 \leq n_2$ and $G[V_1]$ (resp. $G[V_2]$) containing $x_1$ (resp. $x_2$) missing edges and $G[V'_1]$ (resp. $G[V'_2]$) containing $0$ (resp. $x_1 + x_2$) missing edges. The densities for these partitions are:

\[
d(\{V_1, V_2\}) = \frac{x_1 - x_2}{n_1} - \frac{x_2}{n_2}, \quad \text{and} \quad d(\{V'_1, V'_2\}) = \frac{x_1}{n_1} - \frac{x_2}{n_2}.
\]

Since $x = x_1 + x_2$ and $n_1 \leq n_2$, it follows that $d(\{V_1, V_2\}) \leq d(\{V'_1, V'_2\})$.

**Lemma 19.** Among all partitions into $2$ parts containing $0$ (resp. $x$) missing edges in the smaller (resp. larger) part, the one with a maximum number of vertices in the largest part has the best density.

**Proof.** Consider two partitions $\{V_1, V_2\}$ and $\{V'_1, V'_2\}$ such that $|V_1| = n_1$, $|V_2| = n_2$ with $n_1 \leq n_2$ and $|V'_1| = n'_1$, $|V'_2| = n'_2$ with $n'_1 \leq n'_2$ and $G[V_1]$ (resp. $G[V'_1]$) containing $0$ (resp. $x$) missing edges and $G[V'_2]$ (resp. $G[V_2]$) containing $0$ (resp. $x$) missing edges. Moreover suppose $n_2 \leq n'_2$. The densities for these partitions are:

\[
d(\{V_1, V_2\}) = \frac{n_2 - x}{n_2}, \quad \text{and} \quad d(\{V'_1, V'_2\}) = \frac{n'_2 - x}{n'_2}.
\]

Since $n_2 \leq n'_2$, it follows that $d(\{V_1, V_2\}) \leq d(\{V'_1, V'_2\})$.

**Theorem 20.** MAX DENSE GRAPH PARTITION is solvable in polynomial time on graphs $G$ with $n$ vertices with $\delta(G) \geq n-3$.

**Proof.** Let $G$ be a graph of minimum degree $n-3$. We first define a partition $\{V_1, V_2\}$ of the vertices of $G$ by giving vertices color 1 or 2, in the sense that $V_1$ (resp. $V_2$) contains vertices of color 1 (resp. 2). An example is given in Figure 5. We assign color 2 to each vertex of degree $n-1$. Since the minimum degree in $G$ is $n-3$, the graph $H$ of missing edges is a collection of paths and cycles. We color the vertices on paths or cycles with an even number of vertices alternating by 1 and 2. For vertices on paths or cycles with an odd number of vertices we also color them alternating by 1 and 2, always starting with color 2. Thus cycles of odd size have two adjacent vertices of color 2.
We claim that we can bound the density of observation allows to bound cannot be more missing edges than vertices in a part, thus in particular a cycle of odd length creates at least one missing edge. Thus the number of missing edges into two parts. By construction we have maximized the number of vertices in the part with the contains among the missing edges. The sets \( V_1 \) and \( V_2 \) contain the same number of vertices of degree \( n - 2 \) that are extremities of a path with an even number of vertices in \( H \). The set \( V_2 \) contains \( p_o \) more vertices of degree \( n - 2 \), that are extremities of a path with an odd number of vertices, than \( V_1 \). The set \( V_2 \) contains \( o \) more vertices of degree \( n - 3 \) than \( V_1 \). Thus \( n_1 = \frac{1}{2}(n - d_{n-1} - p_o - o) \) and \( n_2 = \frac{1}{2}(n + d_{n-1} + p_o + o) \). We claim that there is no partition into two parts that has a higher density.

By Lemma 17 any partition into two sets contains at least \( o \) missing edges inside the two parts. By construction we have maximized the number of vertices in the part with the missing edges among all partitions with the minimum number \( o \) of missing edges, i.e., there is no partition into two parts \( \{V'_1, V'_2\} \) with \( o \) missing edges all contained in \( V'_2 \) and \( |V'_2| > |V'_1| \). Hence, by Lemmas 18 and 19 it remains to show that any partition \( \{V'_1, V'_2\} \) with \( o + x > o \) missing edges for some \( x > 0 \) has a smaller density than \( \{V_1, V_2\} \).

Let \( \{V'_1, V'_2\} \) be a partition with \( o + x > o \) missing edges for some \( x > 0 \) and assume w.l.o.g. that \( |V'_1| \leq |V'_2| \). By definition of the partition \( \{V_1, V_2\} \), it follows that \( |E(H)| = 2n_1 - p_o + o \) (note that all non-edges have to either be among the \( o \) missing edges in the partition or in the cut between \( V_1 \) and \( V_2 \)). In the partition \( \{V'_1, V'_2\} \), it follows that \( |E(H)| \leq 2|V'_1| - r_1 + (o + x) \), where \( r_1 \) is the number of vertices in \( V'_1 \) adjacent to only one edge in \( H \). In the cut between \( V'_1 \) and \( V'_2 \), each vertex in \( V'_1 \) is adjacent to at most two such edges. Combining these two bounds on \( |E(H)| \) yields

\[
2n_1 - p_o \leq 2|V'_1| - r_1 + x.
\]

We claim that \( r_1 \geq p_o - x \). To see this, observe that every path of odd length either results in a vertex in \( V'_1 \) adjacent to only one edge in \( E(H) \) (\( r_1 \)) or in a missing edge. Also, every cycle of odd length creates at least one missing edge. Thus the number of missing edges \( o + x \) for \( \{V'_1, V'_2\} \) is at least \( p_o - r_1 + o \). Reordering this yields the claimed

\[
r_1 \geq p_o - x.
\]

Inequalities 3 and 4 yield \( 2n_1 - p_o \leq 2|V'_1| - p_o + 2x \) and thus \( n_1 - |V'_1| \leq x \). Since \( \{V'_1, V'_2\} \) is a partition it follows that \( |V'_2| = n - |V'_1| \leq n - n_1 + x = n_2 + x \).

By Lemmas 18 and 19 the best case of missing edges for \( \{V'_1, V'_2\} \) is that they all are in the larger part \( V'_2 \), hence the density of \( \{V'_1, V'_2\} \) is at most \( \frac{n_2 - x}{2} - \frac{o + x}{n_2} \). With \( |V'_2| \leq n_2 + x \), we can bound \( d(V'_1, V'_2) \leq \frac{n_2 - x}{2} - \frac{o + x}{n_2 + x} \). Since \( H \) is of degree at most 2, we know that there cannot be more missing edges than vertices in a part, thus in particular \( o \leq n_2 \). This last observation allows to bound \( d(V'_1, V'_2) \leq \frac{n_2 - x}{2} - \frac{o + x}{n_2} \leq \frac{n_2 - x}{n_2} = d(V_1, V_2) \), thus the density of \( \{V'_1, V'_2\} \) is not larger than the density of \( \{V_1, V_2\} \).
In the rest of the section we consider graphs $G = (V,E)$ on $n$ vertices, $(n-4)$-regular, that is $G = \overline{H}$ where $H$ is a cubic graph. We show that Dense Graph Partition is NP-hard on $(n-4)$-regular graphs, by showing a reduction from Min Uncut on cubic graphs, that is the complement of Max Cut. This last problem on cubic graphs was proved NP-hard and even not polynomial-time 1.003-approximable, unless P=NP \cite{3}.

**Min Uncut**

**Input:** A graph $G = (V,E)$, an integer $k$.

**Question:** Does $G$ contain a partition of $V$ into two parts $A,B$ such that the number of edges with both endpoints in the same part is at most $k$?

Since we reduce from Min Uncut on cubic graphs, we use the following straightforward observation on any partition in such graphs.

▶ **Lemma 21.** For any cubic graph $G$ and any $\{A,B\}$ partition of $V$, we have $|A| + \frac{2}{3} |E(B)| = |B| + \frac{2}{3} |E(A)|$, where $E(A)$, resp. $E(B)$, is the set of edges with both endpoints in $A$, resp $B$.

Since we did not find a reference for the following result in the literature we propose a short proof.

▶ **Lemma 22.** Let $G = (V,E)$ be a cubic graph. There exists a partition $\{A,B\}$ of $G$ with a cut of size at least $|V|$ and it can be found in polynomial time.

**Proof.** Let $P = \{A,B\}$ be a partition of $V$. Consider the following operation: if there is a vertex $v \in A$ (resp. $B$) with at least two neighbors in $A$ (resp. $B$) then $A = A \setminus \{v\}$ (resp. $B = B \setminus \{v\}$) and $B = B \cup \{v\}$ (resp. $A = A \cup \{v\}$). Since the graph is cubic, this operation increases the number of edges between $A$ and $B$ by at least one. Since the number of edges is finite, we can repeat this operation until we obtain a partition $P' = \{A',B'\}$ with no vertex $v \in A'$ (resp. $B'$) with at least two neighbors in $A'$ (resp. $B'$). Since the graph is cubic, if every vertex in $A'$ (resp. $B'$) has at most one neighbor in $A'$, then it has at least two neighbors in $B'$ (resp. $A'$). Consequently $P'$ has a cut of size at least $\frac{2(|A'|+|B'|)}{2} = |V|$. ◀

▶ **Definition 23.** Let $I = (G,k)$ be an instance of Min Uncut where $G = (V,E)$ is a cubic graph. We define the construction $\sigma$ transforming the graph $G$ into the graph $G' := (V',E') = \sigma(G)$ (see Figure 6) as follows:

1. let $G_0 = (V_0,E_0)$ be the union of $\frac{n^2-n}{6}$ copies of $K_{3,3}$ (see remark below). Thus $G_0$ is a cubic bipartite graph with $n^2 - n$ vertices and $V_0$ is the union of two independent sets $L,R$ such that $|L| = |R|$.
2. let $G_1 = (V \cup V_0, E \cup E_0)$.
3. let $G' = \overline{G_1}$.

![Figure 6 The construction of $G'$ in Definition 23](image)
Dense Graph Partitioning on sparse and dense graphs

Remark 24. Note that we can assume that the number of vertices of a cubic graph $G$ is a multiple of 6. Since $G$ is cubic, $n$ is a multiple of 2. If $n$ is not a multiple of 3, we consider the instance $I_{\text{triple}}$ defined as follows: $G_{\text{triple}}$ is the union of 3 copies of $G$ and $k_{\text{triple}} = 3k$, and thus in the new instance $I_{\text{triple}}$ the graph has $3n$ vertices. Note that the number of edges with both endpoints in the same part is $3k$ in $G_{\text{triple}}$ if and only if it is $k$ in $G$.

Let $n = |V|$, $m = |E|$, $n' = |V'|$ and $m' = |E'|$. Observe that $n' = n^2$, and $G'$ is a $(n' - 4)$-regular graph.

Proof. Since the graph $G$ is cubic, $|E(A, B)| = 3 \cdot |A| - 2 \cdot |E(A)| = 3 \cdot |B| - 2 \cdot |E(B)|$. We can deduce that $|A| + \frac{2}{3} \cdot |E(B)| = |B| + \frac{2}{3} \cdot |E(A)|$.

Theorem 25. Dense Graph Partitioning is $NP$-complete on $(n - 4)$-regular graphs with $n$ vertices.

Proof. Let $I = (G = (V, E), k)$ be an instance of $\text{Min UnCut}$, where $G$ is a cubic graph. Consider the following instance $I'$ of Dense Graph Partitioning on the graph $G' = \sigma(G)$ and $d = \frac{n^2}{2} - 1 - \frac{2k}{n^2}$. We claim that $I = (G, k)$ is a yes-instance of $\text{Min UnCut}$ if and only if $I'(G', d)$ is a yes-instance of Dense Graph Partitioning.

Let $\{A, B\}$ be a partition of $V$ whose uncut value is at most $k$. Since $V_0 = L \cup R$, where $L, R$ are independent sets in $G_0$ such that $|L| = |R|$, the sets $L, R$ form two cliques of the same size in $G'$. Let $A' = A \cup L$ and $B' = B \cup R$ and $P = \{A', B'\}$ be a partition of $G'$.

Let $M_{A'}$ and $M_{B'}$ be the set of missing edges in $G'[A']$ and $G'[B']$, respectively. Due to the construction of $G'$, there is no missing edge between $A$ and $L$ and between $B$ and $R$. Thus all missing edges are inside $G'[A \cup B]$, i.e. $|M_{A'}| + |M_{B'}| \leq k$. Thus, the density of the partition $P$ is:

$$d(P) = \frac{|A'| - 1}{2} - \frac{|M_{A'}|}{|A'|} + \frac{|B'| - 1}{2} - \frac{|M_{B'}|}{|B'|} = \frac{n^2 - 2}{2} - \frac{|M_{A'}|}{|A'|} - \frac{|M_{B'}|}{|B'|}$$

We will prove in the following that $d(P) \geq d = \frac{n^2}{2} - 1 - \frac{2k}{n^2}$ that is equivalent to proving that $\frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|} \leq \frac{2(2|M_{A'}| + |M_{B'}|)}{|A'| + |B'|}$.

Consider the difference

$$\frac{2(|M_{A'}| + |M_{B'}|)}{|A'| + |B'|} - \left(\frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|}\right) =$$

$$= \frac{1}{|A'| + |B'|} \left(2|M_{A'}| + 2|M_{B'}| - \frac{|A'| + |B'|}{|A'|}|M_{A'}| - \frac{|A'| + |B'|}{|B'|}|M_{B'}|\right) =$$

$$= \frac{1}{|A'| + |B'|} \frac{1}{|A'|} \frac{1}{|B'|} (|A'| |B'||M_{A'}| + |A'||B'||M_{B'}| - |B'|^2 |M_{B'}| - |A'|^2 |M_{A'}|) =$$

$$= \frac{1}{|A'| + |B'|} \frac{1}{|A'|} \frac{1}{|B'|} (|A'| - |B'|)(|B'||M_{A'}| - |A'||M_{B'}|)$$

Wlog we can consider that $|A'| \geq |B'|$, that implies $|B'| \leq \frac{n^2}{2}$. From Lemma 21 for the cubic graph $G_1$ and partition $\{A', B'\}$, we have $|A'| + \frac{2}{3} |M_{B'}| = |B'| + \frac{2}{3} |M_{A'}|$. Using that $|A'| = n^2 - |B'|$ and $|M_{A'}| = k - |M_{B'}|$, we have $n^2 - |B'| + \frac{2}{3} |M_{B'}| = |B'| + \frac{2}{3} (k - |M_{B'}|)$ and thus $|M_{B'}| = \frac{3}{4} (2 |B'| + \frac{2}{3} k - n^2)$.

Thus,

$$|B'||M_{A'}| - |A'||M_{B'}| = |B'|(k - |M_{B'}|) - (n^2 - |B'|)|M_{B'}| = |B'|k - n^2 |M_{B'}| =$$
We conclude that
\[
\left| B' \right| k - n \frac{3}{4} \left(2 \left| B' \right| + \frac{2}{3} k - n^2 \right) = \left( \left| B' \right| - \frac{n^2}{2} \right) \left( k - \frac{3n^2}{2} \right)
\]
Since \( \left| B' \right| \leq \frac{n^2}{2} \) and \( k \leq \frac{3n^2}{2} \) we can conclude that
\[
\frac{2({|M_{A'}| + |M_{B'}|})}{|A'| + |B'|} - \left( \frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|} \right) \geq 0
\]
Thus, the partition \( P = \{A', B'\} \) has the density \( d(P) \geq d = \frac{n^2}{2} - 1 - \frac{2k}{n^2} \).

Let \( P' \) be a partition of \( G' \) of density \( d(P') \geq d = \frac{n^2-2}{2} - \frac{2k}{n^2} \). We will prove that \( P' \) has exactly two parts \( A' \) and \( B' \) such that \( A = A' \cap V \) and \( B = B' \cap V \) is a partition of \( G \) whose uncut value is at most \( k \).

Suppose that \( |P'| \geq 3 \). Then, using Lemma 3 we have \( d(P') \leq \frac{n^2-|P'|}{2} \leq \frac{n^2-3}{2} = \frac{n^2-2}{2} - \frac{1}{2} \). Since \( k \leq \frac{n^2}{2} \) and \( n \geq 6 \) then \( \frac{k}{n^2} < \frac{1}{2} \). Then \( d(P') < \frac{n^2-2}{2} - \frac{2k}{n^2} = d \) which is a contradiction. Then \( |P'| \leq 3 \).

Suppose that \( |P'| = 1 \). Since \( G' \) is \((n^2 - 4)\)-regular, its density is \( d(P') = \frac{n^2-1}{2} - \frac{3}{2} = \frac{n^2-2}{2} - 1 < \frac{n^2-2}{2} - \frac{2k}{n^2} \) which is a contradiction. Then \( |P'| > 1 \). We conclude that \( |P| = 2 \).

Let \( A' \) and \( B' \) be the two parts of \( P \). Let \( M_{A'} \), resp. \( M_{B'} \), be the set of missing edges in \( G'[A'] \), resp. \( G'[B'] \). Observe that if \( |M_{A'}| + |M_{B'}| \leq k \) then \( |M_{A'}| + |M_{B'}| \leq k \) and then there is a cut of size at least \( k \) between \( A \) and \( B \) in \( G \). What it remains to prove is that \( |M_{A'}| + |M_{B'}| \leq k \).

As a first step we will show the following inequality we need later
\[
\frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|} \leq \frac{|M_{A'}| + |M_{B'}|}{|A'| + |B'|}
\]
In order to prove this, we consider the following difference
\[
\left( \frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|} \right) - \left( \frac{|M_{A'}| + |M_{B'}|}{|A'| + |B'|} \right)
\]
By removing the denominator we get
\[
|M_{A'}||B'| \left( \frac{|A'| + |B'|}{2} + \frac{|M_{A'}| + |M_{B'}|}{3} \right) + |M_{B'}||A'| \left( \frac{|A'| + |B'|}{2} + \frac{|M_{A'}| + |M_{B'}|}{3} \right)
\]
\[
- \left( |M_{A'}| + |M_{B'}| \right) \left( \frac{|A'|}{2} \right) + \left( \frac{|M_{A'}|}{3} \right) + \left( \frac{|M_{B'}|}{3} - \left( \frac{|A'|}{2} \right) \right) + |M_{B'}||A'| \left( \frac{|A'|}{2} + \frac{|M_{B'}|}{3} + \frac{|A'|}{3} - \frac{|B'|}{2} \right)
\]
From Lemma 23 for the cubic graph \( G_1 \) and partition \( \{A', B'\} \), we have \( |A'| = \frac{2}{3} |M_{A'}| = |B'| + \frac{2}{3} |M_{A'}| \), which implies that \( \frac{|A'|}{2} = \frac{|B'|}{2} + \frac{|M_{A'}|}{3} - \frac{|M_{B'}|}{3} \) and \( \frac{|B'|}{2} = \frac{|A'|}{2} + \frac{|M_{B'}|}{3} - \frac{|M_{A'}|}{3} \) and then we get that the previous equality becomes
\[
= |M_{A'}||B'| \left( \frac{|A'| + |M_{B'}|}{2} + \frac{|M_{A'}| + |M_{B'}|}{3} \right) + |M_{B'}||A'| \left( \frac{|A'|}{2} + \frac{|M_{B'}|}{3} + \frac{|M_{A'}|}{3} - \left( \frac{|B'|}{2} + \frac{|M_{A'}|}{3} - \frac{|M_{B'}|}{3} \right) \right)
\]
\[
= |M_{A'}||B'| \left( \frac{2|M_{B'}|}{3} \right) + |M_{B'}||A'| \left( \frac{2|M_{A'}|}{3} \right)
\]
Since \( |M_{A'}|, |M_{B'}|, |A'| \) and \( |B'| \) are positive integers then
\[
\frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|} - \frac{|M_{A'}| + |M_{B'}|}{|A'| + |B'|} \geq 0
\]
We conclude that
\[
\frac{|M_{A'}| + |M_{B'}|}{|A'| + |B'|} \leq \frac{|M_{A'}|}{|A'|} + \frac{|M_{B'}|}{|B'|}.
\]
Finally, we show that $|M_A| + |M_B| \leq k$ using the previous inequality. Let $x = |M_A| + |M_B|$. In order to finalize the proof, we suppose that $x > k$ and we will arrive at a contradiction, that is $d(P') < d$. Consider the following difference

$$d - d(P') = \frac{n^2 - 2}{2} - 2k \cdot \frac{n^2}{n^2} - \left( \frac{n^2 - 2}{2} - \frac{|M_A|}{|A'|} - \frac{|M_B|}{|B'|} \right) = \frac{|M_A|}{|A'|} + \frac{|M_B|}{|B'|} - 2k \cdot \frac{n^2}{n^2}$$

Since $\frac{x}{2} \leq \frac{|M_A|}{|A'|} + \frac{|M_B|}{|B'|}$ then

$$d - d(P') \geq \frac{x}{n^2 + \frac{x}{3}} - 2k \cdot \frac{n^2}{n^2} = \frac{x \cdot n^2 - k \cdot n^2 - 2xk}{n^2} \cdot \frac{n^2}{n^2}$$

Since $x$ and $k$ are integers, then $x \geq k + 1$, and by removing the denominator, we get

$$\geq (k + 1) \cdot \left( n^2 - \frac{2}{3} \cdot k \right) - k \cdot n^2 = n^2 - \frac{2}{3} \cdot k^2 - \frac{2}{3} \cdot k$$

Since $k \leq \frac{n}{2}$, it follows that $n^2 - \frac{2}{3} \cdot k^2 - \frac{2}{3} \cdot k > 0$. This finally gives $d(P') < d$, a contradiction to the choice of $P'$ as partition with density at least $d$, and we hence conclude that $|M_A| + |M_B| \leq k$.

Overall, it follows that if $d(P') \geq n^2 - 2 \cdot \frac{2xk}{n^2}$ then there is a partition $\{A, B\}$ with an uncut of size at most $k$.

At the end of this section we show that a partition into a bounded number of cliques provides a good approximation for graphs of large minimum degree.

**Theorem 26.** Dense Graph Partition is polynomial-time $\frac{n-1}{\delta(G)+1}$-approximable on graphs $G$ with $n$ vertices.

**Proof.** Let $G$ be a graph on $n$ vertices with minimum degree $\delta = \delta(G)$, instance of MAX Dense Graph Partition. If $\delta \geq n - 3$, we can give an optimum solution in polynomial time by Theorem 20. So assume $\delta \leq n - 4$. By Lemma 3 any partition $P$ for the vertices of $G$ satisfies $d(P) \leq \frac{n-1}{2}$. Using Brooks’ theorem, $G$ is $(n - \delta - 1)$-colorable, and further, such a coloring can be computed in polynomial time. (Note that $\delta \leq n - 4$ implies that $G$ is not a complete graph or a circle, the two exceptions in Brooks’ theorem where one more color is needed.) Using such a coloring, $G$ can be partitioned into $n - \delta - 1$ cliques. Then the density of this partition is $\frac{n-(n-\delta-1)}{2} = \frac{\delta+1}{2}$. Comparing this value with the upper bound of $\frac{n-1}{\delta+1}$ on the optimum shows that this partition into $n - \delta - 1$ cliques gives a polynomial-time $\frac{n-1}{\delta+1}$-approximation for Dense Graph Partition.

Notice that if $\delta(G) > \frac{n-1}{2}$, the ratio given in Theorem 26 improves upon the current best ratio of 2 for Dense Graph Partition on general graphs. This approximation can further be used to show the following.

**Theorem 27.** There is an efficient polynomial-time approximation scheme for MAX Dense Graph Partition on graphs $G$ with $n$ vertices and $\delta(G) = n - t$, where $t$ is a constant, $t \geq 4$.

**Proof.** Let $I = G$ be a graph on $n$ vertices and $\delta(G) = n - t$, instance of MAX Dense Graph Partition. We establish in the following the claim. Given $\varepsilon > 0$, consider two cases.

If $n \geq t - 1 + \frac{t-2}{2}$, then let $P$ be a partition that corresponds to a $(t-1)$-coloring of $G$ such that each part is a clique in $G$ as in the proof of Theorem 26. Then $d(P) = \frac{n-1}{2(t+\frac{t}{t+2})} \geq \frac{n-1}{2(1+\varepsilon)} \geq \frac{\text{opt}(I)}{1+\varepsilon}$, where the last inequality $\text{opt}(I) \leq \frac{n-1}{2}$ comes from Lemma 3.
Otherwise, that is $n < t - 1 + \frac{t-2}{\varepsilon}$, enumerate all the partitions of $G$ and consider the best one. Since the number of partitions of $G$ is the Bell number of order $|V| = n$, $B_n$, and $B_n \leq n^n$, we get an optimal solution in time $(1/\varepsilon)^{O(1/\varepsilon)}$.

\section{Conclusion}

In order to have a better understanding of the complexity of \textsc{Max Dense Graph Partition} it would be nice to study it on other graph classes. It was proved to be polynomial-time solvable on trees, but the complexity on graphs of bounded treewidth remains open. Moreover no result exists on split graphs. Concerning approximation, no lower bound was established, it would be nice to improve the 2-approximation algorithm or to show that no polynomial-time approximation scheme exist on general instances.
