Abstract

Left-Right symmetry including supersymmetry presents an important class of gauge models which may possess natural solutions to many issues of phenomenology. Cosmology of such models indicates a phase transition accompanied by domain walls. Such walls must be unstable in order to not conflict with standard cosmology, and can further be shown to assist with open issues of cosmology such as dilution of unwanted relic densities and leptogenesis. In this paper we construct a model of gauge mediated supersymmetry breaking in which parity breaking is also signalled along with supersymmetry breaking and so as to be consistent with cosmological requirements. It is shown that addressing all the stated cosmological issues requires an extent of fine tuning, while in the absence of fine tuning, leptogenesis accompanying successful completion of the phase transition is still viable.

I. INTRODUCTION

Left-Right symmetric model [1, 2, 3, 4, 5] has received considerable attention as a simple extension of the Standard Model (SM). It provides elegant explanation of several open questions of SM in addition to providing a natural explanation for the smallness of neutrino masses [6, 7, 8, 9] via see-saw mechanism [10, 11, 12, 13]. In [14, 15] the possibility that it be consistent as a TeV scale extension of the SM was explored. In the supersymmetric setting it was shown by [16] that $M_R \sim \text{TeV}$ is consistent with $SO(10)$ at $M_X \sim 10^{16}\text{GeV}$. In this paper we adopt a similar approach viz., the scale of Left-Right symmetry can be at TeV to PeV scale, and that supersymmetry (SUSY) is preserved down to the same scale, so that the TeV / PeV scale is protected from unreasonable corrections from higher energy scales\(^1\).

The cosmological phase transition accompanying the parity breakdown is effectively a first order phase transition wherein domains of two different kinds of vacua separated by a network of domain walls (DW) occur\(^{20}\). The need for ensuring a homogeneous Universe in late cosmology requires the phase transition to end appropriately, in particular that this network of domain walls be unstable. The limits on the epoch to which the DW network may survive are placed by the requirements of successful Big Bang Nucleosynthesis (BBN) and cosmic microwave background radiation (CMBR) data. A possible signature for a phase transition ending with decay of domain walls at such energy scales is relic gravitational waves detectable at upcoming experiments\(^{21}\).

The unstable domain walls can have specific physical consequences. One of the possibilities is that they are very slow in disappearing. This is generically true if the difference in values of the effective potential across the wall is small. The energy density of the domain wall complex scales with the cosmological scale factor $a$ as $\rho \propto 1/a$, resulting in $a(t) \propto t^2$ leading to a mild inflationary behaviour. This accords with a proposal of thermal inflation\(^{22}\) (in some contexts called weak inflation) which can help to dilute unwanted relics arising in string theory\(^{23}\)[24].

Unstable domain walls also provide the non-adiabatic conditions for leptogenesis. Theories with majorana neutrino masses and especially with gauged $B - L$ symmetry present the interesting possibility of explaining the baryon asymmetry of the Universe via thermal

---

\(^1\) For reviews of supersymmetry see [17, 18, 19] and references therein.
processes in the early Universe[25]. This particular approach however has been shown to generically require the scale of majorana neutrino mass, equivalently, the scale of gauged \( B - L \) symmetry breaking in relevant models, to be \( 10^{11}-10^{13} \) GeV [26, 27], with a more optimistic constraint \( M_{B-L} > 10^9 \) GeV [28, 29]. On the other hand, it has been shown [30, 31] that the only real requirement imposed by Leptogenesis is that the presence of heavy neutrinos should not erase lepton asymmetry generated by a given mechanism, possibly non-thermal. This places the modest bound \( M_1 > 10^4 \) GeV, on the mass of the lightest of the heavy majorana neutrinos.

There are two possible scenarios which exploit this window of low mass scale for leptogenesis. One is the “soft leptogenesis”, [32, 33, 34, 35] relying on the decay of scalar superpartners of neutrino and a high degree of degeneracy [36] in the mass eigenvalues due to soft SUSY breaking terms. Another possibility for leptogenesis is provided by the unstable domain walls. This mechanism is analogous to that explored for the electroweak baryogenesis [37], provided a source for \( CP \) asymmetry can be found. It has been shown [38] that the domain walls occurring in models such as to be studied in this paper generically give spatially varying complex masses to neutrinos. Unstable domain walls of our models are therefore sufficient to ensure the required leptogenesis.

In an earlier work two of the authors have explored the possibility of consistent cosmology in this class of models, primarily the questions of removal of unwanted relics[39] and the role of domain walls as possible catalysers of leptogenesis[40]. Exact Left-Right symmetry of the underlying model however does not permit instability of the domain walls. In [39] it was shown that this circumstance is avoided provided supersymmetry breaking in the hidden sector also breaks parity symmetry and this is signalled through the soft terms.

Several proposals have been made for successful phenomenological implementation of SUSY in a Left-Right symmetric gauge theory [41, 42, 43, 44, 45]. Implications of gauge mediation of SUSY in the same was studied in [46, 47]. More recently, this model has been studied in the context of the LHC in [48, 49] and also a similar low energy model in the context of cosmology in [50]. In all such models considered, spontaneous gauge symmetry breaking required to recover SM phenomenology also leads to observed parity breaking. However, for cosmological reasons it is not sufficient to ensure local breakdown of parity. It has been earlier proposed [51] that the occurrence of the SM like sector globally, i.e., homogeneously over the entire Universe, could be connected to the SUSY breaking effects.
from the hidden sector.

Here we pursue this question in the context of two classes of models, one represented by Aulakh, Benakli, Melfo, Rasin and Senjanovic \cite{45,43} (ABMRS) and the other, proposed recently in Babu and Mohapatra, \cite{49} (BM) both of which circumvent thorny issue of phenomenologically acceptable vacua by making minimal extensions of the basic scheme. The former uses two triplets $\Omega$ and $\Omega_u$ neutral under $U(1)_{B-L}$ while the latter uses one superfield $S$ singlet under all the proposed gauge interactions as well as parity. In the approach we adopt, namely preservation of the Left-Right symmetry to low energies, both these models have a generic issue regarding occurrence of domain walls in cosmology which needs to be addressed. However the walls can be easily removed without conflicting with phenomenology even with very small parity breaking effects. In gauge mediated supersymmetry breaking GMSB, the SUSY breaking effects are naturally small due to being communicated at one loop and two loop orders. We propose the required (GMSB) scheme to obtain natural conditions for SUSY breaking and also for the disappearance of the domain walls. We show that the smallness migrates into parity breaking and is adequate to ensure global choice of true ground state in the Universe.

In sec. II we discuss the two models ABMRS and BM. In sec. III we discuss the soft terms arising in these models and the constraints imposed by consistent cosmology; presenting some of the concerned formulae in the appendix A. In sec IV we pursue the consequence of implementing generic GMSB in these theories. In sec. V we propose a modification of the scheme to implement combined breaking of SUSY as well as parity in a manner consistent with low energy symmetries and successful cosmology. Section VI contains discussion of our results.

II. MINIMAL SUPERSYMMETRIC LEFT-RIGHT MODEL : A RECAP

The quark, lepton and Higgs fields for the minimal left-right SUSY model, with their respective quantum numbers under the gauge group $SU(3)_c \otimes SU(2)_L \otimes SU(2)_R \otimes U(1)_{B-L}$
are given by,
\[ Q = (3, 2, 1, 1/3), \quad Q_c = (3^*, 1, 2, -1/3), \]
\[ L = (1, 2, 1, -1), \quad L_c = (1, 1, 2, 1), \]
\[ \Phi_i = (1, 2, 2, 0), \quad \text{for } i = 1, 2, \]
\[ \Delta = (1, 3, 1, 2), \quad \bar{\Delta} = (1, 3, 1, -2), \]
\[ \Delta_c = (1, 1, 3, -2), \quad \bar{\Delta}_c = (1, 1, 3, 2). \] (1)

where we have suppressed the generation index for simplicity of notation. In the Higgs sector, the bidoublet $\Phi$ is doubled to have non-vanishing CKM matrix, whereas the $\Delta$ triplets are doubled to have anomaly cancellation. Under discrete parity symmetry the fields are prescribed to transform as,
\[ Q \leftrightarrow Q_c^*, \quad L \leftrightarrow L_c^*, \quad \Phi_i \leftrightarrow \Phi_i^\dagger, \]
\[ \Delta \leftrightarrow \Delta_c^*, \quad \bar{\Delta} \leftrightarrow \bar{\Delta}_c^*. \] (2)

However, this minimal left-right symmetric model is unable to break parity spontaneously [41, 42]. Inclusion of nonrenormalizable terms gives a more realistic structure of possible vacua [52][43, 44]. Such terms were studied for the case when the scale of $SU(2)_R$ breaking is high, close to Planck scale. We shall not pursue this possibility here further, retaining interest in TeV to PeV scale phenomenology.

A. The ABMRS model with a pair of triplets

Due to difficulties with the model discussed above, an early model to be called minimal by its authors is ABMRS[43, 44, 45]. Here two triplet fields $\Omega$ and $\Omega_c$, were added, with the following quantum numbers,
\[ \Omega = (1, 3, 1, 0), \quad \Omega_c = (1, 1, 3, 0), \] (3)

which was shown to improve the situation with only the renormalisable terms[43, 45, 53]. It was shown that this model breaks down to minimal supersymmetric standard model (MSSM) at low scale. This model was studied in the context of cosmology in [39, 51] specifically, the mechanism for leptogenesis via Domain Walls in [40].
The superpotential for this model is given by,

\[ W_{LR} = h_{l}^{i} L^{T} \tau_{2} \Phi_{i} \tau_{2} L_{c} + h_{q}^{i} Q^{T} \tau_{2} \Phi_{i} \tau_{2} Q_{c} + if L^{T} \tau_{2} \Delta L + if c^{T} \tau_{2} \Delta c L_{c} \]

\[ + m_{\Delta} \text{Tr} \Delta \bar{\Delta} + m_{\Delta} \text{Tr} \Delta_{c} \bar{\Delta}_{c} + \frac{m_{\Omega}}{2} \text{Tr} \Omega^{2} + \frac{m_{\Omega}}{2} \text{Tr} \Omega_{c}^{2} \]

\[ + \mu_{ij} \text{Tr} \tau_{2} \Phi_{i}^{T} \tau_{2} \Phi_{j} + a \text{Tr} \Delta \Omega \bar{\Delta} + a \text{Tr} \Delta_{c} \Omega \bar{\Delta}_{c} \]

\[ + \alpha_{ij} \text{Tr} \Omega \Phi_{i}^{T} \tau_{2} \Phi_{j} + \alpha_{ij} \text{Tr} \Omega_{c} \Phi_{i}^{T} \tau_{2} \Phi_{j} \tau_{2} . \]  

(4)

Since supersymmetry is broken at a very low scale, we can employ the \( F \) and \( D \) flatness conditions obtained from the superpotential, to get a possible solution for the vacuum expectation values (vev’s) for the Higgs fields.

\[ \langle \Omega \rangle = 0, \quad \langle \Delta \rangle = 0, \quad \langle \bar{\Delta} \rangle = 0, \]

\[ \langle \Omega_{c} \rangle = \begin{pmatrix} \omega_{c} & 0 \\ 0 & -\omega_{c} \end{pmatrix}, \quad \langle \Delta_{c} \rangle = \begin{pmatrix} 0 & 0 \\ d_{c} & 0 \end{pmatrix}, \quad \langle \bar{\Delta}_{c} \rangle = \begin{pmatrix} 0 & \bar{d}_{c} \\ 0 & 0 \end{pmatrix}. \]  

(5)

This solution set is of course not unique. Since the original theory is parity invariant a second solution for the \( F \) and \( D \) flat conditions exists, with Left type fields’ vev’s exchanged with those of the Right type fields [39, 40].

With vev’s as in eq. (5) the pattern of breaking is

\[ SU(2)_{L} \otimes SU(2)_{R} \otimes U(1)_{B-L} \xrightarrow{M_{R}} SU(2)_{L} \otimes U(1)_{R} \otimes U(1)_{B-L} \]

\[ \xrightarrow{M_{B-L}} SU(2)_{L} \otimes U(1)_{Y} \]  

(6) (7)

It was observed [43] that supersymmetric breaking imposes a condition on the scales of breaking, with respect to the electroweak scale \( M_{W} \).

\[ M_{R} M_{W} \simeq M_{B-L}^{2} \]  

(8)

This relation raises the interesting possibility that the scale of \( M_{R} \) can be as low as \( 10^{4} \) to \( 10^{6} \) GeV, with corresponding very low scale \( 10^{3} \) to \( 10^{4} \) GeV of lepton number violation, opening the possibility of low energy leptogenesis [31][40].

**B. The BM model with a single singlet**

An independent approach to improve the minimal model with introduction of a parity odd singlet [54], was adopted in [41, 42]. However this was shown at tree level to lead to charge-breaking vacua being at a lower potential than charge-preserving vacua.
Recently, an alternative to this has been considered in [49] where a superfield $S = (1, 1, 1, 0)$ also singlet under parity is included in addition to the minimal set of Higgs required as in eq. (1). The superpotential is given by,

$$W_{LR} = W^{(1)} + W^{(2)}$$

Where

$$W^{(1)} = h_{i}^{(1)} L^{T} \tau_{2} \Phi_{i} \tau_{2} L_{c} + h_{i}^{(0)} Q^{T} \Phi_{i} \tau_{2} Q_{c}$$

$$+ i f^{i} L^{T} \tau_{2} \Delta L + i f L^{c T} \tau_{2} \Delta_{c} L_{c}$$

$$+ S [ \lambda^{*} \text{Tr} \Delta \bar{\Delta} + \lambda \text{Tr} \Delta_{c} \bar{\Delta}_{c} + \lambda_{a}^{*} \text{Tr} \Phi_{a}^{T} \tau_{2} \Phi_{b} \tau_{2} - M_{R}^{2} ]$$

$$W^{(2)} = M_{\Delta} \text{Tr} \Delta \bar{\Delta} + M_{\Delta}^{*} \text{Tr} \Delta_{c} \bar{\Delta}_{c}$$

$$+ \mu_{a}^{i} \text{Tr} \Phi_{a}^{T} \tau_{2} \Phi_{b} \tau_{2} + M_{s} S^{2} + \lambda_{s} S^{3}$$

For a variety of phenomenological reasons[49], the terms in $W^{(2)}$ may be assumed to be zero. The presence of linear terms in $S$ in $W^{(1)}$ makes possible the following SUSY vacuum,

$$\langle S \rangle = 0, \quad \lambda v_{R} \bar{v}_{R} + \lambda^{*} v_{L} \bar{v}_{L} = M_{R}^{2}$$

In the ABMRS model, the introduction of a separate $\Omega$ field for each of the sectors $L$ and $R$ permits local preference of one sector over the other through spontaneous symmetry breaking. The preference however remains strictly local. Another region of space can equally well have vacuum of another type. In the BM model however, due to the $S$ field being neutral including under parity, such a distinction cannot arise even locally. This is reflected in the above equation (11) where we have a flat direction in the $v_{L} - v_{R}$ space. A more general treatment of the possible vacua is included in appendix A. Nevertheless,

$$v_{L} = \bar{v}_{L} = 0, \quad |v_{R}| = |\bar{v}_{R}| = \frac{M_{R}}{\sqrt{\lambda}}$$

is a possible vacuum[49] in which we recover the known phenomenology.

The important result is that after SUSY breaking and emergence of SUSY breaking soft terms, integrating out heavy sleptons modifies the vacuum structure due to Coleman-Weinberg type one-loop terms which must be treated to be of same order as the other terms in $V_{eff}$. Accordingly, it is shown[49] that the $V_{eff}$ contains terms of the form

$$V_{1-loop}^{eff}(\Delta_{c}) \sim - |f|^{2} m_{L_{e}}^{2} \text{Tr} (\Delta_{c} \Delta_{c}^{\dagger}) A_{1}^{R} - |f|^{2} m_{L_{e}}^{2} \text{Tr} (\Delta_{c} \Delta_{c}) \text{Tr} (\Delta_{c}^{\dagger} \Delta_{c}^{\dagger}) A_{2}^{R}$$

---

2 The first equation of sec. 3, of [49] is a special case of our condition (11)
where $A_1^R$ and $A_2^R$ are constants obtained from expansion of the effective potential. Presence of these terms is shown to lead to the happy consequence of a preference for electric charge preserving vacuum over the charge breaking vacuum, provided $m_{L}^2 < 0$.

For the purpose of the present paper it is important to note that even assuming that some soft terms will lift the flat direction in (11), we still have no source of breaking $L-R$ symmetry. This means that

$$v_R = \bar{v}_R = 0, \quad |v_L| = |\bar{v}_L| = \frac{M_R}{\sqrt{\lambda}}$$

also constitutes a valid solution of eq. (11). In this vacuum the soft terms can give rise to the following terms in the effective potential,

$$V_{1-loop}^{eff}(\Delta) \sim -|f|^2m_L^2\text{Tr}(\Delta\Delta^\dagger)A_1^L - |f|^2m_L^2\text{Tr}(\Delta\text{Tr}(\Delta^\dagger\Delta^\dagger)A_2^L$$

with $A_1^L$ and $A_2^L$ constants. Thus the choice of known phenomenology is only one of two possible local choices, and formation of domain walls is inevitable.

III. COSMOLOGY OF BREAKING AND SOFT TERMS

Due to the existence of two different sets of solutions for the possible vev’s, formation of domain walls (DW) is inevitable [39, 40] in both the models considered above. Stable walls are known to overclose the Universe[20][55] and are undesirable. However, a small inequality in the free energies in the vacua on the two sides of the walls is sufficient to destabilize them. The lower bound on the temperature upto which such walls may persist in the Universe is set by the known physics of BBN, $T \sim 1MeV$. Let the temperature by which the wall complex has substantially decayed, in particular has ceased to dominate the energy density of the Universe, be $T_D$. It has been estimated that the free energy density difference $\delta \rho$ between the vacua which determines the pressure difference across a domain wall should be of the form [56][57]

$$\delta \rho \sim T_D^4$$

in order for the DW to disappear at the scale $T_D$.

It has been observed in [58] that parity breaking effects suppressed by Planck scale are sufficient to remove the DW. Black Holes can carry only locally conserved charges, and therefore there would exist processes in Quantum Gravity which do not conserve global
charges as well as violate discrete symmetry such as parity. Thus we expect parity breaking terms induced by quantum gravity in the effective lagrangian. Assuming that the pressure across the walls is created by terms such as $C\varphi^6/M_{Pl}^2$, it is easy to check that reasonable range of values of the order parameter $\langle \varphi \rangle$ and $T_D$ exist for which the walls can disappear without conflicting with cosmology. This is especially true of high scale models, $M_R \gtrsim 10^{11}$ GeV. We shall be interested in a low (PeV) scale model where Planck scale effects can be ignorable and where the parity breaking should arise from known effects which can be counterchecked against other observables.

In ABMRS model at the scale $M_R$, $SU(2)_R \otimes U(1)_{B-L}$ breaks to $U(1)_R \otimes U(1)_{B-L}$, equally well, $SU(2)_L \otimes U(1)_{B-L}$ breaks to $U(1)_L \otimes U(1)_{B-L}$ depending on which of the two $\Omega$ fields acquires a vev. Thus domain walls are formed at the scale $M_R$. At a lower scale $M_{B-L}$ when the Higgs triplet $\Delta$’s get vev, $U(1)_R \otimes U(1)_{B-L}$ breaks to $U(1)_Y$ or $U(1)_L \otimes U(1)_{B-L}$ breaks to $U(1)_{Y'}$. In BM model the breaking is directly to $SU(2)_L \otimes U(1)_{Y}$ or equally well, $SU(2)_R \otimes U(1)_{Y'}$. As per the analysis reported above we are assuming that the $S$ field does not acquire a vev. Thus in each of the models we have MSSM after the $M_{B-L}$ or the $M_R$ scale, respectively. SUSY breaking soft terms emerge below the SUSY breaking scale $M_S$. We now proceed with the stipulation advanced in [51] that the role of the hidden sector dynamics is not only to break SUSY but also break parity. This permits in principle a relation between observables arising from the two apparently independent breaking effects.

The soft terms which arise in the two models ABMRS and BM may be parameterized as follows

\begin{align}
\mathcal{L}_{soft}^1 &= m_1^2 \text{Tr}(\Delta\Delta^\dagger) + m_2^2 \text{Tr}(\bar{\Delta}\bar{\Delta}^\dagger) \\
&\quad + m_3^2 \text{Tr}(\Delta_c\Delta_c^\dagger) + m_4^2 \text{Tr}(\bar{\Delta}_c\bar{\Delta}_c^\dagger) \\
\mathcal{L}_{soft}^2 &= \alpha_1 \text{Tr}(\Delta\Omega\Delta^\dagger) + \alpha_2 \text{Tr}(\bar{\Delta}\bar{\Omega}\bar{\Delta}^\dagger) \\
&\quad + \alpha_3 \text{Tr}(\Delta_c\Omega_c\Delta_c^\dagger) + \alpha_4 \text{Tr}(\bar{\Delta}_c\bar{\Omega}_c\bar{\Delta}_c^\dagger) \\
\mathcal{L}_{soft}^3 &= \beta_1 \text{Tr}(\Omega\Omega^\dagger) + \beta_2 \text{Tr}(\Omega_c\Omega_c^\dagger) \\
\mathcal{L}_{soft}^4 &= S[\gamma_1 \text{Tr}(\Delta\Delta^\dagger) + \gamma_2 \text{Tr}(\bar{\Delta}\bar{\Delta}^\dagger)] \\
&\quad + S^*[\gamma_3 \text{Tr}(\Delta_c\Delta_c^\dagger) + \gamma_4 \text{Tr}(\bar{\Delta}_c\bar{\Delta}_c^\dagger)] \\
\mathcal{L}_{soft}^5 &= \bar{\sigma}^2 |S|^2
\end{align}

(17) (18) (19) (20) (21)
For ABMRS model the relevant soft terms are given by,

\[ \mathcal{L}_{\text{soft}} = \mathcal{L}_{\text{soft}}^1 + \mathcal{L}_{\text{soft}}^2 + \mathcal{L}_{\text{soft}}^3 \] (22)

For BM model the soft terms are given by,

\[ \mathcal{L}_{\text{soft}} = \mathcal{L}_{\text{soft}}^1 + \mathcal{L}_{\text{soft}}^4 + \mathcal{L}_{\text{soft}}^5 \] (23)

Using the requirement of eq. (16) we can constrain the differences between the soft terms in the Left and Right sectors [39, 40]. According to eq. (11) S field does not acquire a vev in the physically relevant vacua and hence the terms in eq.s (20) and (21) do not contribute to the vacuum energy. The terms in eq. (18) are suppressed in magnitude relative to those in eq. (19) due to having Ω vev’s to one power lower. This argument assumes that the magnitude of the coefficients α are such as to not mix up the symmetry breaking scales of the Ω’s and the Δ’s.

To obtain orders of magnitude we have taken the \( m_i^2 \) parameters to be of the form \( m_1^2 \sim m_2^2 \sim m^2 \) and \( m_3^2 \sim m_4^2 \sim m^2 \) [40] with \( T_D \) in the range \( 10 - 10^3 \) GeV [24]. For both the models we have taken the value of the Δ vev’s as \( d \sim 10^4 \) GeV. For ABMRS model additionally we take \( \omega \sim 10^6 \) GeV. The resulting differences required for successful removal of domain walls are shown in Table I.

We see from table I that assuming both the mass-squared differences \( m^2 - m'^2 \) and \( \beta_1 - \beta_2 \) arise from the same dynamics, Ω fields are the determinant of the cosmology. This is because the lower bound on the wall disappearance temperature \( T_D \) required by Ω fields is higher and the corresponding \( T_D \) is reached sooner. This situation changes if for some reason Ω’s do not contribute to the pressure difference across the walls. The BM model does not have Ω’s and falls in this category.

| \( T_D/\text{GeV} \) | \( \sim \) | 10^2 | 10^3 |
|------------------|---------|------|------|
| \( (m^2 - m'^2)/\text{GeV}^2 \) | \( \sim \) | 10^{-4} | 1 | 10^4 |
| \( (\beta_1 - \beta_2)/\text{GeV}^2 \) | \( \sim \) | 10^{-8} | 10^{-4} | 1 |

TABLE I: Differences in values of soft supersymmetry breaking parameters for a range of domain wall decay temperature values \( T_D \). The differences signify the extent of parity breaking.
During the period of time in between destabilization of the DW and their decay, leptogenesis occurs due to these unstable DW as discussed in [38, 40]. After the disappearance of the walls at the scale $T_D$, electroweak symmetry breaks at a scale $M_{EW} \sim 10^2$ GeV and standard cosmology takes over. In the next section we discuss the implementation of GMSB scenario for these models.

IV. GAUGE MEDIATED SUSY BREAKING IN MINIMAL SUPERSYMMETRIC MODELS

In gauge mediated SUSY breaking proposal, dynamical breaking of SUSY in a hidden sector is communicated to visible sector through a field $X$ singlet under visible gauge interactions, and one or more conjugate pairs of chiral superfields called messenger fields which together constitute a vector like, anomaly free representation [59, 60, 61]. For reviews the reader may refer [17, 62, 63]. The choice of charges for the messenger fields ensures that they do not spoil gauge coupling unification. A simple choice is to choose them to be complete representations of the possible grand unification group, which in the Left-Right symmetric case is $SO(10)$.

The dynamical SUSY breakdown causes the messenger fields to develop SUSY violating interactions with the hidden sector, while they also interact with the (s)quarks, (s)leptons and Higgs(inos) via gauge and gauginos interactions. Gaugino fields get a mass at one loop due to these interactions, while gauge invariance prevents gauge fields from acquiring any mass. As such supersymmetry is broken in the visible sector.

We denote the messenger sector fields to be $\Phi_i$ and its complex conjugate representation to be $\bar{\Phi}_i$, with $i$ indexing the set of several possible messengers. These couple to a chiral superfield singlet $X$ via yukawa type interaction.

$$W = \sum_i y_i X \Phi_i \bar{\Phi}_i,$$

(24)

It should be noted that in the case of BM model, this $X$ could be identified with $S$. Coupling of $X$ to the hidden sector gives rise to vacuum expectation values $\langle X \rangle$ and $\langle F_X \rangle$ for its scalar and auxiliary parts respectively. As such the fermionic and scalar parts of the messenger sector get masses,

$$m_f^2 = |y_i \langle X \rangle|^2, \quad m_s^2 = |y_i \langle X \rangle|^2 \pm |y_i \langle F_X \rangle|$$

(25)
Thus, the degeneracy between the fermionic and scalar part of the messenger sector vanishes.

Gaugino mass arises due to one loop diagrams and is given [60]

\[ M_a = \frac{\alpha_a}{4\pi} \left( \frac{\langle F_X \rangle}{\langle X \rangle} \right) (1 + O(x)), \quad (a = 1, 2, 3) \]  

(26)

where \( x = \frac{\langle F_X \rangle}{(\lambda \langle X \rangle)^2} \). Masses for the scalars of the SUSY model for Left-Right symmetric case arises due to two loop corrections and is given by

\[ m_\phi^2 = 2 \left( \frac{\langle F_X \rangle}{\langle X \rangle} \right)^2 \left[ \left( \frac{\alpha_3}{4\pi} \right)^2 C_3^\phi + \left( \frac{\alpha_2}{4\pi} \right)^2 (C_{2L}^{\phi} + C_{2R}^{\phi}) + \left( \frac{\alpha_1}{4\pi} \right)^2 C_1^\phi \right] (1 + O(x)). \]  

(27)

The \( C_a^\phi \) are the Casimir group theory invariants defined by,

\[ C_a^\phi \delta^j_i = (T^a T^a)_i^j, \]  

(28)

where \( T^a \) is the group generator of the group which acts on the scalar \( \phi \). Since we consider both the models (ABMRS and BM), the values of \( C_a^\phi \)s for the fields are given by,

\[
C_3^\phi = \begin{cases} 
4/3 & \text{for } \phi = Q, Q_c \\
0 & \text{for } \phi = \Phi_i, \Delta', \Omega, L', S, \end{cases} \\
C_2^{\phi L} = \begin{cases} 
3/4 & \text{for } \phi = Q, L, \Phi_i \\
2 & \text{for } \phi = \Delta, \bar{\Delta}, \Omega \\
0 & \text{for } \phi = Q_c, L_c, \Delta_c, \bar{\Delta}_c, \Omega_c, S, \end{cases} \\
C_2^{\phi R} = \begin{cases}

\]

(29)

These contributions, will eventually translate into soft SUSY breaking terms, and in case of BM the desired effective potential to produce charge preserving vacuum. However, there is no signal of global parity breakdown and the problem of domain walls persists. In the next section we propose a modification of this standard GMSB to explain parity breaking.

V. CUSTOMIZED GMSB FOR LEFT-RIGHT SYMMETRIC MODELS

The differences required between the soft terms of the Left and the Right sector for the DW to disappear at a temperature \( T_D \) as given in Table I are very small. Reasons for
appearance of this small asymmetry between the Left and the Right fields is hard to explain since the original theory is parity symmetric. However, we now try to explain the origin of this small difference by focusing on the hidden sector, and relating it to SUSY breaking.

For this purpose we assume that the strong dynamics responsible for SUSY breaking also breaks parity, which is then transmitted to the visible sector via the messenger sector and encoded in the soft supersymmetry breaking terms. We implement this idea by introducing two singlet fields $X$ and $X'$, respectively even and odd under parity.

$$X \leftrightarrow X, \quad X' \leftrightarrow -X'. \quad (30)$$

The messenger sector superpotential then contains terms

$$W = \sum_n \left[ \lambda_n X \left( \Phi_{nL} \Phi_{nL} + \Phi_{nR} \Phi_{nR} \right) + \lambda'_n X' \left( \Phi_{nL} \Phi_{nL} - \Phi_{nR} \Phi_{nR} \right) \right] \quad (31)$$

For simplicity, we consider $n = 1$. The fields $\Phi_L, \bar{\Phi}_L$ and $\Phi_R, \bar{\Phi}_R$ are complete representations of a simple gauge group embedding the L-R symmetry group. Further we require that the fields labelled $L$ get exchanged with fields labelled $R$ under an inner automorphism which exchanges $SU(2)_L$ and $SU(2)_R$ charges, e.g. the charge conjugation operation in $SO(10)$. As a simple possibility we consider the case when $\Phi_L, \bar{\Phi}_L$ (respectively, $\Phi_R, \bar{\Phi}_R$) are neutral under $SU(2)_R \ (SU(2)_L)$. Generalization to other representations is straightforward.

As a result of the dynamical SUSY breaking we expect the fields $X$ and $X'$ to develop nontrivial vev’s and $F$ terms and hence give rise to mass scales

$$\Lambda_X = \frac{\langle F_X \rangle}{\langle X \rangle}, \quad \Lambda_{X'} = \frac{\langle F_{X'} \rangle}{\langle X' \rangle}. \quad (32)$$

Both of these are related to the dynamical SUSY breaking scale $M_S$, however their values are different unless additional reasons of symmetry would force them to be identical. Assuming that they are different but comparable in magnitude we can show that Left-Right breaking can be achieved simultaneously with SUSY breaking being communicated.

In the proposed model, the messenger fermions receive respective mass contributions

$$m_{fL} = |\lambda \langle X \rangle + \lambda' \langle X' \rangle| \quad (33)$$

$$m_{fR} = |\lambda \langle X \rangle - \lambda' \langle X' \rangle|$$
while the messenger scalars develop the masses

\[ m_{\phi L}^2 = |\lambda(X) + \lambda'(X')|^2 \pm |\lambda(F_X) + \lambda'(F_{X'})| \]

\[ m_{\phi R}^2 = |\lambda(X) - \lambda'(X')|^2 \pm |\lambda(F_X) - \lambda'(F_{X'})| \]

We thus have both SUSY and parity breaking communicated through these particles.

As a result the mass contributions to the gauginos of SU(2)_L and SU(2)_R from both the X and X' fields with their corresponding auxiliary parts take the simple form,

\[ M_{aL} = \frac{\alpha_a \lambda(F_X) + \lambda'(F_{X'})}{4\pi} \frac{|\lambda(X) + \lambda'(X')|^2}{1 + O(x_L)} \]

\[ M_{aR} = \frac{\alpha_a \lambda(F_X) - \lambda'(F_{X'})}{4\pi} \frac{|\lambda(X) - \lambda'(X')|^2}{1 + O(x_R)} \]

with

\[ x_L = \frac{\lambda(F_X) + \lambda'(F_{X'})}{|\lambda(X) + \lambda'(X')|^2} \]

\[ x_R = \frac{\lambda(F_X) - \lambda'(F_{X'})}{|\lambda(X) - \lambda'(X')|^2} \]

Here \( a = 1, 2, 3 \). In turn there is a modification to scalar masses, through two-loop corrections, expressed to leading orders in the \( x_L \) or \( x_R \) respectively, by the generic formulae

\[ m_{\phi L}^2 = 2 \left( \frac{\lambda(F_X) + \lambda'(F_{X'})}{\lambda(X) + \lambda'(X')} \right)^2 \left[ \left( \frac{\alpha_3}{4\pi} \right)^2 C_3^\phi + \left( \frac{\alpha_2}{4\pi} \right)^2 C_{2L}^\phi + \left( \frac{\alpha_1}{4\pi} \right)^2 C_1^\phi \right] \]

\[ m_{\phi R}^2 = 2 \left( \frac{\lambda(F_X) - \lambda'(F_{X'})}{\lambda(X) - \lambda'(X')} \right)^2 \left[ \left( \frac{\alpha_3}{4\pi} \right)^2 C_3^\phi + \left( \frac{\alpha_2}{4\pi} \right)^2 C_{2R}^\phi + \left( \frac{\alpha_1}{4\pi} \right)^2 C_1^\phi \right] \]

where, the values of \( C_i^\phi \)'s are given by Eqn. (29). Applying these formulae to \( \Delta \) and \( \Omega \), the parameters \( m_i^2 \)'s and \( \beta_i \)'s appearing in eqn.s (17) and (19) respectively can be calculated. The difference between the mass squared of the left and right sectors are obtained as

\[ \delta m_{\Delta}^2 = 2 \left[ \left( \frac{\lambda(F_X) + \lambda'(F_{X'})}{\lambda(X) + \lambda'(X')} \right)^2 - \left( \frac{\lambda(F_X) - \lambda'(F_{X'})}{\lambda(X) - \lambda'(X')} \right)^2 \right] \left\{ \left( \frac{\alpha_2}{4\pi} \right)^2 + \frac{6}{5} \left( \frac{\alpha_1}{4\pi} \right)^2 \right\} \]

\[ = 2(\Lambda_X)^2 \left[ \left( \frac{1 + \tan \gamma}{1 + \tan \sigma} \right)^2 - \left( \frac{1 - \tan \gamma}{1 - \tan \sigma} \right)^2 \right] \left\{ \left( \frac{\alpha_2}{4\pi} \right)^2 + \frac{6}{5} \left( \frac{\alpha_1}{4\pi} \right)^2 \right\} \]

where we have brought \( \Lambda_X \) out as the representative mass scale and parameterised the ratio of mass scales by introducing

\[ \tan \gamma = \frac{\lambda'(F_{X'})}{\lambda(F_X)}, \quad \tan \sigma = \frac{\lambda'(X')}{\lambda(X)} \]
Adequate \((m^2 - m'^2)\) \(10^{-8} \quad 10^{-4} \quad O(1)\)
Adequate \((\beta_1 - \beta_2)\) \(10^{-12} \quad 10^{-8} \quad 10^{-4}\)

TABLE II: Entries in this table are the values of the parameter \(\gamma - \sigma\), assuming it is small, required to ensure wall disappearance at temperature \(T_D\) displayed in the header row. The table should be read in conjunction with table I, with the rows corresponding to each other. In the last column first row, \(\gamma\) and \(\sigma\) are not assumed to be small, and the entry signifies the value of the square bracket in eq. (41), which is generically a quantity \(\sim O(1)\).

Similarly,

\[
\delta m^2_{\Omega} = 2(\Lambda_X)^2 \left[ \left( \frac{1 + \tan \gamma}{1 + \tan \sigma} \right)^2 - \left( \frac{1 - \tan \gamma}{1 - \tan \sigma} \right)^2 \right] \left( \frac{\alpha_2}{4\pi} \right)^2
\]

In the models studied here, the ABMRS model will have contribution from both the above kind of terms. The BM model will have contribution only from the \(\Delta\) fields.

The contribution to lepton masses is also obtained from eq. (40). This can be used to estimate the magnitude of the overall scale \(\Lambda_X\) to be \(\geq 30\) TeV [63] from collider limits.

Returning to cosmology requirements, we see from table I that the required mass-squared differences are rather small, and hence it is required to assume that ratios \(\tan \gamma\) and \(\tan \sigma\) must be small. Under this assumption, we expand the quantity in square brackets in eqs (41) and (43) in small quantities to find its magnitude \(4(\gamma - \sigma) + O(\gamma^2, \sigma^2)\). The resulting requirement on the values this small parameter is shown in Table II for various values of \(T_D\), the scale at which the DW finally disappear.

VI. CONCLUSION

In Left-Right symmetric models, domain walls generically arise in cosmology. It is necessary to assume the presence of dynamics that eventually signals departure from exact Left-Right symmetry. In the absence of such a dynamics the universe would remain trapped in an unacceptable phase. We have explored models where the scale of Left-Right symmetry and the accompanying gauged \(B - L\) symmetry are both low, within a few orders of magnitude of the electroweak scale. In earlier work we have obtained bounds on the parity
breaking parameters so that domain walls do not conflict with phenomenology, at the same time providing mechanisms for leptogenesis as well as weak inflation[22, 23]. The latter is an effective ways of diluting the density of unwanted relics[24]. Wall disappearance is a nonadiabatic phenomenon and could leave behind imprints on primordial gravitational wave background [21].

The possibilities considered in this paper fall into two categories, whether weak inflation is permitted or not. Leptogenesis is permitted in all the cases considered here. Weak inflation becomes possible if the domain walls linger around for a substantial time, dominating the energy density of the universe for a limited period. The walls are long lived if the pressure difference across the walls is small, as happens if the parity breaking effects are small and difference in effective potential across the walls is small.

In this paper we have explored the possibility that smallness of the parity breaking effect is related to the indirect supersymmetry breaking effects. To be specific we have studied two viable implementations of Left-Right symmetry, the ABMRS and BM models discussed in section II, and studied them in the context of gauge mediated supersymmetry breaking as the mechanism. We have explored a variant of the latter mechanism in order to achieve parity breaking to be signalled from within the dynamical supersymmetry breaking sector. Dynamical symmetry breaking effects are associated with strong dynamics and parity is usually susceptible to breaking in their presence.

Our implementation of GMSB contains two ringlets $X$, even under parity and $X'$ odd under parity in the hidden sector and coupled to messengers. Obtaining small parity breaking effect in this context generically requires that the scales of the vev’s of $X$ and $X'$ be finely tuned to the same value as seen in table II. While this is not unnatural since the strong dynamics is unknown, it raises the need to explore the latter further. In this case all the cosmological requirements can be met.

From table I we see that given that the same dynamics determines the soft terms in $\Delta$ and $\Omega$ effective lagrangians, the lower bound on $T_D$ required by $\Omega$ fields is higher, thus determining the $T_D$. On the other hand from table II, we see that given a desirable value of $T_D$ the terms in $\Delta$ lagrangian require less fine tuning than the those in the $\Omega$ lagrangian. Since in the BM model the singlet does not signal any new mass scale, it is the scale of $\Delta$ vev’s which determines the $T_D$. For this reason it would be more natural model from the point of view of cosmology.
The ABMRS model becomes equally good a contender if for some reason the $\Omega$ vev scale does not enter the wall disappearance mechanism. One way this could occur is if the SUSY breaking effects were communicated primarily to the $\Delta$ sector but not the $\Omega$ sector. In a class of models considered in [46, 47] SUSY breaking gets communicated by fields charged only under $B - L$ and no other charges. Since the $\Omega$ are neutral under $B - L$ they would receive the SUSY breaking effects only as higher order effects. In this category of SUSY breaking models ABMRS would require less fine tuning to ensure solution of all the cosmological issues studied here.

APPENDIX A: VACUA IN THE BM MODEL

Here we discuss some details of the minimization conditions for the BM model. We begin with the full renormalizable superpotential for the BM model

$$ W_{LR} = h_l^{(i)} L^T_{\tau_2} \Phi_i \tau_2 L_c + h_q^{(i)} Q^T_{\tau_2} \Phi_i \tau_2 Q_c $$

$$ + i f^* L^T_{\tau_2} \Delta L + i f L^T_{\tau_2} \Delta_c L_c $$

$$ + S \left[ \lambda^* \text{Tr } \Delta \tilde{\Delta} + \lambda \text{Tr } \Delta_c \tilde{\Delta}_c + \lambda'_{ab} \text{Tr } \Phi_a^T_{\tau_2} \Phi_b \tau_2 - M_R^2 \right] $$

$$ + M_\Delta \text{Tr } \Delta \tilde{\Delta} + M_\Delta^* \text{Tr } \Delta_c \tilde{\Delta}_c $$

$$ + \mu_{ab} \text{Tr } \Phi_a^T_{\tau_2} \Phi_b \tau_2 + M_s S^2 + \lambda_s S^3 $$ \hspace{1cm} (A1)

The resulting expressions for the $F$ terms are,

$$ F_s = -[\lambda^* \text{Tr } \Delta \tilde{\Delta} + \lambda \text{Tr } \Delta_c \tilde{\Delta}_c - M_R^2 + 2M_s S + 3\lambda_s S^2]^* $$ \hspace{1cm} (A2)

$$ F_\Delta = -[S \lambda^* \Delta + M_\Delta \tilde{\Delta}]^* $$ \hspace{1cm} (A3)

$$ F_{\tilde{\Delta}} = -[S \lambda^* \Delta + M_\Delta \Delta]^* $$ \hspace{1cm} (A4)

$$ F_{\Delta_c} = -[S \lambda \Delta_c + M_\Delta^* \tilde{\Delta}_c]^* $$ \hspace{1cm} (A5)

$$ F_{\tilde{\Delta}_c} = -[S \lambda \Delta_c + M_\Delta \Delta_c]^* $$ \hspace{1cm} (A6)
From these we assemble the potential for the scalar fields in standard notation,

\[ V = |F_s|^2 + |F_\Delta|^2 + |F_{\Delta c}|^2 + |F_{\Delta c}^\dagger|^2 \]

\[ = |\lambda^* \text{Tr} \Delta \bar{\Delta} + \lambda \text{Tr} \Delta_c \bar{\Delta}_c - M_R^2 + 2M_sS + 3\lambda_sS^2|^2 \]

\[ + |S\lambda^* + M_\Delta|^2 \text{Tr} \Delta \bar{\Delta}_c \text{Tr} \Delta \bar{\Delta}_c^\dagger \]

\[ + |S\lambda + M_\Delta^*|^2 \text{Tr} \Delta_c \bar{\Delta}_c \text{Tr} \Delta_c \bar{\Delta}_c^\dagger \]

\[ = |\lambda^* v_L \bar{v}_L + \lambda v_R \bar{v}_R - M_R^2 + 2M_sS + 3\lambda_sS^2|^2 \]

\[ + |S\lambda^* + M_\Delta|^2 (|\bar{v}_L|^2 + |v_L|^2) + |S\lambda + M_\Delta^*|^2 (|\bar{v}_R|^2 + |v_R|^2) \]  \(\text{(A7)}\)

The resulting minimization conditions for the vev’s are

\[ \frac{\delta V}{\delta S} = (2M_s + 6\lambda_sS) Q^* + \lambda^* (S\lambda^* + M_\Delta)^* (|\bar{v}_L|^2 + |v_L|^2) \]

\[ + \lambda (S\lambda + M_\Delta^*)^* (|\bar{v}_R|^2 + |v_R|^2) = 0 \]  \(\text{(A8)}\)

\[ \frac{\delta V}{\delta v^*_L} = \lambda^* \bar{v}_L Q^* + |S\lambda^* + M_\Delta|^2 v^*_L = 0 \]  \(\text{(A9)}\)

\[ \frac{\delta V}{\delta \bar{v}_L} = \lambda^* v_L Q^* + |S\lambda + M_\Delta|^2 \bar{v}_L^* = 0 \]  \(\text{(A10)}\)

\[ \frac{\delta V}{\delta v^*_R} = \lambda \bar{v}_R Q^* + |S\lambda + M_\Delta^*|^2 v^*_R = 0 \]  \(\text{(A11)}\)

\[ \frac{\delta V}{\delta \bar{v}_R} = \lambda v_R Q^* + |S\lambda + M_\Delta|^2 \bar{v}_R^* = 0 \]  \(\text{(A12)}\)

where

\[ Q = \lambda^* v_L \bar{v}_L + \lambda v_R \bar{v}_R - M_R^2 + 2M_sS + 3\lambda_sS^2 \]  \(\text{(A13)}\)

Thus the desired class of vacua eq. (11) is obtained provided we ignore the \(W^{(2)}\) of eq. (10) in the text and choose \(\langle S\rangle\) to be zero.
