A new class of BFGS updating formula based on the new quasi-newton equation

Basim A. Hassan, Hussein K. Khalo
Department of Mathematics, College of Computers Sciences and Mathematics, University of Mosul, Iraq.

ABSTRACT
Quasi-Newton methods are amongst the mainly useful and competent iterative process for solving unrestrained minimization functions. In this paper we derive a new quasi-Newton equation with on the Hessian estimate updates and alterations intended at developing their performance. The “Numerical results” illustrate that the proposed technique useful for the known test functions.

1. INTRODUCTION
Uncovering a solution to a general broad degree nonlinear optimization Problem:

\[ \min \ell(x), \ x \in R^n \]

where \( \ell \) is a smooth function of \( n \) variables, by quasi-Newton methods is painstaking. Quasi-Newton methods are awfully useful utensils for solving unrestrained optimization problems [1]. At the \( k \) th iteration of the quasi-Newton method, a symmetric and non negative definite \( B_k \) is known, and a search direction is computed by:

\[ d_k = -B_k^{-1}J_k, \]

where \( J_k \) is the gradient of \( \ell \) evaluated at the current iterate \( x_k \). One then computes the next iterate by:

\[ x_{k+1} = x_k + \alpha_k d_k \]

It computed a step length \( \alpha_k \) that make sure the approval of the Wolfe conditions:
\[ \ell(x_k + \alpha_k d_k) \leq \ell(x_k) + \delta \alpha_k J_k^T d_k \]  
\[ d_k^T J(x_k + \alpha_k d_k) \geq \sigma d_k^T J_k \]

where \( 0 < \delta < \sigma < 1 \). For more details can be found in [2]. By tradition, \([B_k]\) satisfies the quasi-Newton equation:

\[ B_{k+1} \hat{\partial}_k = p_k , \]

where \( \hat{\partial}_k = x_{k+1} - x_k \) and \( p_k = J_{k+1} - J_k \). Let \( H_k \) be the inverse of \( B_k \). The famous inverse update \( H_k \)

is the standard BFGS formula:

\[ H_{BFGS}^{k+1} = H_k - \frac{H_k p_k \hat{\partial}_k^T + \hat{\partial}_k p_k^T H_k}{\hat{\partial}_k^T p_k} + \left[ 1 + \frac{p_k^T H_k p_k}{\hat{\partial}_k^T p_k} \right] \hat{\partial}_k \hat{\partial}_k^T \]

Certainly, BFGS method is one of the most excellent methods and doing to now for solving (1). For more details can be found in [3]. A lot of approaches have been suggested to find better the quasi-Newton Hessian estimate updates. In this fragment we sketch a few latest suggested updates take by modifying the vector \( p_k \), as shown in Table 1.

| Name methods | Difference in gradients | References |
|--------------|-------------------------|------------|
| P            |                        | (4)        |
| LF           |                        | (5)        |
| WLQ          |                        | (6)        |
| ZDC          |                        | (7)        |

Table 1. Modifying The Vector

The idea of variant QN methods had been studied by many researchers for example, [8], [9].

Now we will derive new quasi-Newton equations and analyze its convergence.

2. DERIVING NEW QUASI-NEWTON EQUATION AND ALGORITHM

In this fragment we derive the new quasi-Newton equations. Therefore we can apply it to functions more general than quadratic as from:

\[ \ell_k = \ell_{k+1} - J_{k+1}^T \partial_k - \frac{1}{2} \partial_k^T U_{k+1} \partial_k + \frac{1}{6} \partial_k^T T_{k+1} \partial_k \]

where \( T_{k+1} \) is the tensor of \( \ell \) at the point \( x_k \). we attain, by revoking the conditions which comprise the tensor:

\[ \partial_k^T U_{k+1} \partial_k = p_k^T \partial_k + 6(\ell_k - \ell_{k+1}) + 3(J_{k+1} + J_k)^T \partial_k \]
For more details can be found in [10]. So, would like derivative of manages to formulate general quadratic, we have:

$$
\frac{1}{2} \partial_k^T U_{k+1} \partial_k = \frac{1}{2} p_k^T \partial_k + 3(\ell_k - \ell_{k+1}) + \frac{3}{2} (J_{k+1} + J_k)^T \partial_k
$$

(10)

The step size scalar $\alpha_k$, which minimizes $\ell(x_k)$, is approximated by:

$$
\alpha_k = - \frac{J_k^T d_k}{d_k^T U d_k}
$$

(11)

After some algebraic manipulations one obtains:

$$
\partial_k^T U_{k+1} \partial_k = \frac{1}{2} p_k^T \partial_k + 3(\ell_k - \ell_{k+1}) + \frac{3}{2} J_{k+1}^T \partial_k + J_k^T \partial_k
$$

(12)

Since $B_{k+1} \partial_k$ is need to estimated $U_{k+1} \partial_k$, it is reasonable to need:

$$
\partial_k^T B_{k+1} \partial_k = \frac{1}{2} p_k^T \partial_k + 3(\ell_k - \ell_{k+1}) + \frac{3}{2} J_{k+1}^T \partial_k + J_k^T \partial_k
$$

(13)

A good choice to estimate $B_{k+1} \partial_k$ is known by:

$$
B_{k+1} \partial_k = p_k^*, \quad p_k^* = \frac{1}{2} p_k + \frac{3(\ell_k - \ell_{k+1}) + 3/2(J_{k+1}^T \partial_k) + J_k^T \partial_k}{\partial_k^T p_k} \omega_k
$$

(14)

where $u_k$ is any vector such that $\partial_k^T \omega_k \neq 0$.

Varieties of this quasi-Newton equations differ in the way of selecting the vector $\omega_k$ in (14) we have the forms:

1. First case $\omega_k = p_k$ gives:

$$
B_{k+1} \partial_k = p_k^*, \quad p_k^* = \frac{1}{2} p_k + \frac{3(\ell_k - \ell_{k+1}) + 3/2(J_{k+1}^T \partial_k) + J_k^T \partial_k}{\partial_k^T p_k} p_k
$$

(15)

2. Second case $\omega_k = J_{k+1}$ gives:

$$
B_{k+1} \partial_k = p_k^*, \quad p_k^* = \frac{1}{2} p_k + \frac{3(\ell_k - \ell_{k+1}) + 3/2(J_{k+1}^T \partial_k) + J_k^T \partial_k}{\partial_k^T J_{k+1}} J_{k+1}
$$

(16)

Different change gradient used in quasi-Newton equation for yield different quasi-Newton methods.

The new CBFGS algorithm can be stated formally as follows.

Step 1: Data $x_0 \in R^n$ and $H_0 = I$ , Set $k = 0$.

Step 2: Stop if $\|J_k\| = 0$.

Step 3: Calculate $d_k$ by:

$$
d_k = - H_k J_k
$$

Step 4: Finds a $\alpha_k$ which satisfies the (4) and (5).

Step 5: Iterative process be as $x_{k+1} = x_k + \alpha_k d_k$.

\textit{A new class of BFGS updating formula based on the new quasi-newton equation (Basim A. Hassan)}

Step 6: Update $H_0$ for times to find $H_{k+1}$ by (7) and (14).
Step 7: Put $k = k + 1$. Go to step 2.

A property positive definite of $H_k$ is awfully important, can be verify in the next theorem.

**Theorem 2.1.**

Let $(\alpha_k, x_{k+1}, J_{k+1}, d_{k+1})$ be generated by the new algorithm. Then $B_{k+1}$ is positive definite for all $k$ provided that $\partial_k^T p_k^* > 0$.

**Proof.**

Now, we evaluate the quantity $\partial_k^T y_k^*$. If the step length $\alpha_k$ satisfies the Wolfe conditions (4) and (5), then we have:

$$
\partial_k^T p_k^* = \frac{1}{2} p_k^T \nabla_k + 3(\ell_k - \ell_{k+1}) + \frac{3}{2} J_{k+1} \nabla_k + J_{k+1} \nabla_k
$$

$$
= 3(\ell_k - \ell_{k+1}) + \frac{1}{2} J_k \nabla_k + J_{k+1} \nabla_k
$$

$$
\geq \left[ \frac{1}{2} - 3\delta + \sigma \right] J_k \nabla_k
$$

(17)

To attain this intention, prefer the values of $\sigma$ and $\delta$ with $1/2 > \delta > 1/3$ and $1/2 - 3\delta + \sigma < 0$. Noting the $\partial_k^T J_k = \alpha_k d_k^T J_k < 0$, we know that there exists a constant $m < 0$ such that:

$$
\partial_k^T p_k^* \geq m d_k^T J_k > 0
$$

(18)

The proof is complete.

3. **GLOBAL PROPERTY**

We ready the local convergence property of the modified BFGS method. The following assumption is required.

**Assumption**

(i) The level set $S = \{ x \in R^n | \ell(x) \leq \ell(x_0) \}$ is bounded.

(ii) The function $f$ is twice continuously differentiable on $S$ and there exists a constant $L > 0$ such that:

$$
\left\| J(x) - J(y) \right\| \leq L \left\| x - y \right\|
$$

(19)

Since $\{\ell_k\}$ is a diminishing series, it is obvious that the series $\{x_k\}$ generated by new Algorithm is enclosed in $S$, and there exists a constant $\ell^*$ such that:

$$
\lim_{k \to \infty} \ell_k = \ell^*
$$

(20)

(iii) The function $\ell$ is uniformly convex, i.e., there exist positive constants $M$ and $m$ such that:

$$
m \|d\|^2 \leq d^T U(x)d \leq M \|d\|^2
$$

(21)
holds for all $x \in S$ and $d \in R^n$, where $U(x) = \nabla^2 \ell(x)$. These assumptions are the same as those in [11].

**Theorem 2.2.**

Let $\{x_k\}$ be generated by the new algorithm. Then we have:

\[
m \|\delta^T_k p^*_k\| \leq \|\delta^T_k p^*_k\| \leq m \|\delta^T_k \delta_k\|,\]

\[
\|p^*_k\| \leq (L + M) \|\delta_k\|,\]

and

\[
\sum_{k=1}^{\infty} \alpha_k J_k^T d_k \leq + \infty\]

**Proof.**

Following the definition of $p^*_k$ and the Taylor's series, we get:

\[
\delta^T_k p^*_k = \frac{1}{2} p^T_k \delta_k + 3(\ell - \ell_{k+1}) + \frac{3}{2} J^T_{k+1} \delta_k + J^T_k \delta_k
\]

\[
= p^T_k \delta_k + 6(\ell - \ell_{k+1}) + 3(J_{k+1} + J_k)^T \delta_k
\]

\[
= 4J^T_{k+1} \delta_k + 2J^T_k \delta_k + 6(\ell - \ell_{k+1})\]

By using Taylor's series, and mean value theorem, we get:

\[
\ell = \ell_{k+1} - J^T_{k+1} \delta_k + \frac{1}{2} \delta^T_k U(\eta_k) \delta_k\]

From (24) and (25) we get:

\[
s^T_k p^*_k = \frac{1}{2} p^T_k \delta_k + 3(\ell - \ell_{k+1}) + \frac{3}{2} J^T_{k+1} \delta_k + J^T_k \delta_k
\]

\[
= p^T_k \delta_k + 6(\ell - \ell_{k+1}) + 3(J_{k+1} + J_k)^T \delta_k
\]

\[
= 4\delta^T_k U(\eta_k) \delta_k - (\ell - \ell_{k+1}) + 2J^T_k \delta_k + 6(\ell - \ell_{k+1})
\]

By using quadratic function, and mean value theorem, we have:

\[
\ell_{k+1} = \ell_k + \delta^T_k J^T k + \frac{1}{2} \delta^T_k U(\eta_k) \delta_k\]

Therefore, it follows from (26) and (27) that:

\[
\delta^T_k p^*_k = 2\delta^T_k U(\eta_k) \delta_k + 2J^T_k \delta_k + 2(\ell - \ell_{k+1})
\]

\[
= 2\delta^T_k U(\eta_k) \delta_k - \delta^T_k U(\eta_k) \delta_k
\]

\[
= \delta^T_k U(\eta_k) \delta_k\]

where

\[
\eta_k = x_k + \xi(x_{k+1} - x_k) \text{ and } \xi \in (0, 1)\]
Mingling with Assumption (iii), it is simple to catch:

\[ m \| \vartheta_k \|^2 \leq \vartheta_k^T P_k^* \leq M \| \vartheta_k \|^2 \]  

(30)

Using definition of \( P_k^* \) and the Taylor’s series once more, we get:

\[
\| P_k \| = \left\| \frac{1}{2} p_k + \frac{3(\ell_k - \ell_{k+1}) + 3/2(J_k^T \vartheta_k) + J_k^T \vartheta_k \omega_k}{\vartheta_k \omega_k} \right\| \\
\leq \frac{1}{2} \| p_k \| + \frac{3(\ell_k - \ell_{k+1}) + 3/2(J_k^T \vartheta_k) + J_k^T \vartheta_k}{\| \vartheta_k \| \| \omega_k \|} \\
\leq \frac{1}{2} \| p_k \| + \frac{\| \vartheta_k \|}{\| \vartheta_k \|} \| \omega_k \| \\
\leq \| p_k \| + \frac{\| \vartheta_k \|}{\| \vartheta_k \|} \leq L \| \vartheta_k \| + M \| \vartheta_k \| \\
\leq \left( L + M \right) \| \vartheta_k \| 
\]

(31)

Now we turn to the proof of (23). By the WWP rule (4) and Assumption (ii) we obtain:

\[-(1 - \sigma) J_k^T d_k \leq (J_{k+1} - J_k)^T d_k \leq L \alpha_k \| d_k \|^2 \]  

(32)

This yields that:

\[ \alpha_k \geq \frac{-\left(1 - \sigma\right) J_k^T d_k}{L \| d_k \|^2} = \frac{(1 - \sigma) d_k^T B_k d_k}{L \| d_k \|^2} \geq \frac{(1 - \sigma) m}{L} = \bar{\alpha}_k \]  

(33)

Conversely, from (1), we obtain:

\[ \sum_{k=1}^{\infty} (\ell_k - \ell_{k+1}) = \lim_{N \to \infty} \sum_{k=1}^{N} (\ell_k - \ell_{k+1}) = \lim_{N \to \infty} (\ell_1 - \ell_{N+1}) = \ell_1 - \ell^* \]  

(34)

Thus,

\[ \sum_{k=1}^{\infty} (\ell_k - \ell_{k+1}) \leq +\infty, \]  

(35)

which mixed with the WWP law (4) that is:

\[ \sum_{k=1}^{\infty} -\alpha_k J_k^T d_k \leq +\infty \]  

(36)

Currently we established the worldwide convergence of new Algorithm.

**Theorem 2.3.**

Let \( \{ x_k \} \) be created by new Algorithm and let \( \ell \) satisfies Assumptions i and ii. Suppose to facilitate there exists constants \( K_1 \) and \( K_2 \) such the subsequent relation:
\[ \| B_k \partial_k \| \leq \kappa_1 \| \partial_k \| \text{ and } \partial_k^T B_k \partial_k \geq \kappa_2 \| \partial_k \|^2 \]  

(37)

holds. Then we have:

\[ \lim_{k \to \infty} \| J_k \| = 0 \]  

(38)

**Proof.**

We proceed by contradiction, we assume \( \| J_k \| \geq \varepsilon \) for all \( k \) with some positive constant \( \varepsilon \). Taking into account \( B_k \partial_k = \alpha_k B_k d_k = -\alpha_k J_k \), then \( \| J_k \|^2 = (1/\alpha_k)^2 \| B_k \partial_k \|^2 \), we get from (36) that:

\[
\infty > \sum_{k=1}^{\infty} (-J_k^T d_k) \geq \sum_{k=1}^{\infty} (-J_k^T d_k) \\
= \sum_{k=1}^{\infty} \frac{1}{\alpha_k} \partial_k^T B_k \partial_k = \sum_{k=1}^{\infty} \alpha_k \frac{\| J_k \|^2}{\| B_k \partial_k \|^2} \partial_k^T B_k \partial_k \\
\geq \sum_{k=1}^{\infty} \alpha_k \varepsilon^2 \kappa_1 \kappa_2^{-1} = \infty
\]  

(39)

where the inequality follows from \( \alpha_k \geq \bar{\alpha}_k \) and the modified update \( \partial_k \partial_k + \kappa_2 \| \partial_k \|^2 \), which concludes the proof.

4. **NUMERICAL RESULTS AND DISCUSSION**

Now, we details the numerical results for Algorithms CBFGS and BFGS. The problems that we tested are from [12,13]. Himmelblau used the next stop law see in [14] “If \( |\ell(x_k)| < 10^{-5} \), let \( \text{stop } 1 = |\ell(x_k) - \ell(x_{k+1})| / |\ell(x_k)| \); Otherwise, let \( \text{stop } 1 = |\ell(x_k) - \ell(x_{k+1})| \). For each problem, if \( \| J_k \| < \varepsilon \) or \( \text{stop } 1 < 10^{-5} \) was satisfied, the program will be stopped. All codes were written in MATLAB 4.4 and Windows XP operation system. The parameters are chosen as: \( \delta = 0.1 \), \( \sigma = 0.9 \), \( \varepsilon = 10^{-5} \) and the initial matrix \( B_0 = I \) is the unit matrix”. Table 1 explains the results, where the columns contain the following implying:

- **Problem**: the name of the test problem in MATLAB;
- **Dim**: the dimension of the problem;
- **NI**: the number of iterations;
- **NF**: the number of function evaluations.

Their numerical experience signify that numerous updates from this idea labored well in applied, specially the modified update \( \omega_k = J_{k+1} \) but the modified update \( \omega_k = p_k \) give a slight improvement over the original BFGS method. Comparison of several amounts between different quasi-Newton methods as shown in Table 1.

Generally, we can compute the percentage performance of the new proposed algorithms compared against the standard BFGS algorithm for the general tools NI and NF as follows. Relative efficiency of the new algorithms as shown in Table 2.
Table 1. Comparison of Several Amounts Between Different Quasi-Newton Methods

5. CONCLUSIONS

In this paper, we supported the new QN-equation, we’ve got projected some new quasi-Newton strategies. The convergence results and also the understanding experimentation make sure that the approach explicit during this paper is fruitful.
