Face reduction and the immobile indices approaches to regularization of linear Copositive Programming problems

Kostyukova O.I.*    Tchemisova T.V.†

Abstract

The paper is devoted to the regularization of linear Copositive Programming problems which consists of transforming a problem to an equivalent form, where the Slater condition is satisfied and the strong duality holds. We describe here two regularization algorithms based on the concept of immobile indices and an understanding of the important role these indices play in the feasible sets’ characterization. These algorithms are compared to some regularization procedures developed for a more general case of convex problems and based on a facial reduction approach. We show that the immobile-index-based approach combined with the specifics of copositive problems allows us to construct more explicit and detailed regularization algorithms for linear Copositive Programming problems than those already available.

Key words. Linear copositive programming, strong duality, normalized immobile index set, regularization, minimal cone, facial reduction, constraint qualifications

1 Introduction

Conic optimization is a subfield of convex optimization that studies the problems of minimizing a convex function over the intersection of an affine subspace and a convex cone. For a gentle introduction to conic optimization and a survey of its applications in Operations Research and related areas, we refer interested readers to [15] and the references therein. Copositive Programming (CoP) problems form a special class of conic problems and can be considered as an optimization over the convex cone of so-called copositive matrices (i.e. matrices which are positive semi-defined on the non-negative orthant). Copositive models arise in many important applications, including \(NP\)-hard problems. For the references on motivation and application of CoP see, e.g. [3, 7, 8]. In linear CoP, the objective function is linear and the constraints are formulated with the help of linear matrix functions. Linear copositive problems are closely related to that of linear Semi-Infinite Programming (SIP) and Semidefinite Programming (SDP). Copositive and semidefinite

problems are particular cases of SIP problems, but CoP deals with more challenging and less studied problems than SDP. The literature on the theory and methods of SIP, CoP, and SDP is quite extensive. We refer the interested readers to [1, 2, 3, 8, 25, 26], and the references in these works.

In convex and conic optimization, optimality conditions, and duality results are usually formulated under certain regularity conditions, so-called constraint qualifications (CQ) (see, e.g. [2, 10, 22, 26]). Such conditions should guarantee the fulfillment of the Karush-Kuhn-Tucker (KKT)-type optimality conditions and the strong duality property consisting in the fact that the optimal values of the primal problem and the corresponding Lagrangian dual one are equal and the dual problem attains its maximum. Strong duality is the cornerstone of convex optimization, playing a particularly important role in the stability of numerical methods.

Unfortunately, even in convex optimization, many problems cannot be classified as regular (i.e. satisfying some regularity conditions such as, for example, strict feasibility). In [9], we read: "...new optimization modeling techniques and convex relaxations for hard nonconvex problems have shown that the loss of strict feasibility is a more pronounced phenomenon than has previously been realized". This phenomenon can occur because of either the poor choice of functions that describe feasible sets or the degeneration of the feasible sets themselves. According to [23], sometimes the loss of a certain CQ "...is a modeling issue rather than inherent to the problem instance..." which "...justifies the pleasing paradigm: efficient modeling provides for a stable program".

Thus, the idea of a regularization appears quite naturally which is aimed at obtaining an equivalent and more convenient reformulation of the problem with some required properties, one of which is that the regularized problem must satisfy the generalized Slater condition.

The first papers on regularization of abstract convex problems (the regularization procedures are called pre-processing there) appeared in the 1980-th, being followed by various publications for special classes of conic problems (see, e.g. [5, 6]). Nevertheless, as Drusvyatskiy and Wolkowicz wrote in [9] published in 2017, for conic optimization in general, research in the field of regularization algorithms is still in its infancy. At the same time, the authors of [9] confirm that to make a regularization algorithm viable, it is necessary to actively explore the structure of the problem since for some specific applications of conic optimization, the rich basic structure makes regularization quite possible and leads to significantly simplified models and enhanced algorithms.

Several approaches to the regularization of conic optimization problems are proposed in the literature. In [5, 6], the concept of the minimal cone of constraints was used by Borwein and Wolkowicz for regularization of abstract convex and conic convex problems for which any CQ fails. An algorithm, proposed there for the description of the minimal cone, is based on a successive reduction of cone’s faces and was named by the authors the Facial Reduction Algorithm (FRA).

A different approach was proposed by Luo, Sturm, and Zhang (see [17] and the references therein) which is called the dual regularization or conic expansion. This approach tries to close a duality gap (the difference between the primal and dual optimal values) of the regularized problems by expanding the dual constraints’ cone.

In [24], Waki and Muramatsu applied the facial reduction approach to a conic optimization problem in such a way that each primal reduced cone is dual to the cone generated by the conic expansion approach.

The facial reduction approach has been successfully applied to SDP and the second-order cone programming problems, as well as to certain classes of optimization problems over symmetric
(i.e. self-dual and homogeneous) and nice cones (see, e.g. [18, 19, 20, 21]). At the same time, the question of effective constructive application of this approach to other classes of problems remains open. This is because the known FRAs are more conceptual than practical. In this paper, based on the results from [11, 13, 14], we develop a different approach to regularization of linear CoP problems. This approach is based on the concept of immobile indices, i.e. indices of the constraints that are active for all feasible solutions.

The purpose of the paper is to

a) describe in details a finite algorithm for regularization of linear CoP problems that is based on the concept of immobile indices but does not require any additional information about them;

b) compare two approaches to regularization of the linear CoP problems, one based on the facial reduction and the other based on the concept of immobile indices, and the corresponding regularized problems constructed using these approaches.

To the best of our knowledge, in CoP there has never been an attempt to develop detailed and easy in implementation algorithms, based on the minimal cone representation (see, e.g. the FRA in [5, 6] and the modified FRA in [24]). Nor do we have any information about any other attempts to describe constructive regularization procedures for linear copositive problems. The regularization algorithms presented in the paper are new, original, and timely due to the growing number of eminent applications of CoP.

The paper is organized as follows. Section 1 hosts Introduction. Section 2 contains equivalent formulations of the linear CoP problem and the basic definitions. In section 3, we describe different ways of regularization of copositive problems. In subsection 3.1, we describe the minimal face regularization from [5, 6] when it is applied to linear CoP problems; in 3.2, we shortly describe the proposed in [14] one-step regularization based on the concept of immobile indices and compare the regularized problems obtained in subsections 3.1 and 3.2. Section 4 contains iterative algorithms for regularization of linear copositive problems: the Waki and Muramatsu’s facial reduction algorithm is described in 4.1, a new regularization algorithm based on the immobile index set together with its compressed modification is described in 4.2, followed by a short discussion on the iterative algorithms. Section 5 contains some conclusions.

2 Linear copositive programming problem: equivalent formulations and basic definitions

Given an integer \( p > 1 \), denote by \( \mathbb{R}^p_+ \) the set of all \( p \) vectors with non-negative components, by \( S(p) \) and \( S_+(p) \) the space of real symmetric \( p \times p \) matrices and the cone of symmetric positive semidefinite \( p \times p \) matrices, respectively, and let \( \mathcal{COP}^p \) stay for the cone of symmetric copositive \( p \times p \) matrices:

\[
\mathcal{COP}^p := \{ D \in S(p) : t^\top Dt \geq 0 \ \forall t \in \mathbb{R}^p_+ \}.
\]

The space \( S(p) \) is considered here as a vector space with the trace inner product

\[
A \cdot B := \text{trace} (AB).
\]

Consider a linear copositive programming problem in the form

\[
\min_{x \in \mathbb{R}^n} \ c^\top x, \quad \text{s.t.} \ A(x) \in \mathcal{COP}^p,
\]

(1)
where \( x = (x_1, ..., x_n)^\top \) is the vector of decision variables. The data of the problem are presented by vector \( c \in \mathbb{R}^n \) and the constraints matrix function \( \mathbf{A}(x) \) defined in the form

\[
\mathbf{A}(x) := \sum_{i=1}^{n} A_i x_i + A_0,
\]

with given matrices \( A_i \in S(p) \), \( i = 0, 1, \ldots, n \).

It is well known (see e.g. \cite{1}) that the copositive problem (I) is equivalent to the following convex SIP problem:

\[
\min_{x \in \mathbb{R}^n} c^\top x, \quad \text{s.t.} \; t^\top \mathbf{A}(x)t \geq 0 \; \forall t \in T,
\]

with a \( p \)-dimensional compact index set in the form of a simplex

\[
T := \{t \in \mathbb{R}_+^p : e^\top t = 1\},
\]

where \( e = (1, 1, ..., 1)^\top \in \mathbb{R}^p \).

Denote by \( X \) the feasible set of the equivalent problems (I) and (3):

\[
X := \{x \in \mathbb{R}^n : \mathbf{A}(x) \in \mathcal{COP}^p\} = \{x \in \mathbb{R}^n : t^\top \mathbf{A}(x)t \geq 0 \; \forall t \in T\}.
\]

In what follows, we will suppose that \( X \neq \emptyset \).

Evidently, the set \( X \) is convex.

**Remark 1** Since \( X \neq \emptyset \), then without loss of generality, we can consider that \( A_0 \in \mathcal{COP}^p \). Indeed, by fixing a feasible solution \( y \in X \) and substituting the variable \( x \) by a new variable \( z := x - y \), we can replace the original problem (I) by the following one in terms of \( z \):

\[
\min_{z \in \mathbb{R}^n} c^\top z, \quad \text{s.t.} \; \bar{\mathbf{A}}(z) \in \mathcal{COP}^p,
\]

with \( \bar{\mathbf{A}}(z) := \sum_{i=1}^{n} A_i z_i + \bar{A}_0 \), \( \bar{A}_0 := \mathbf{A}(y) \in \mathcal{COP}^p \).

According to the commonly used definition, the constraints of the copositive problem (I) satisfy the Slater condition if

\[
\exists \bar{x} \in \mathbb{R}^n \text{ such that } \mathbf{A}(\bar{x}) \in \text{int} \mathcal{COP}^p = \{D \in S(p) : t^\top Dt > 0 \; \forall t \in \mathbb{R}_+^p, \; t \neq 0\}.
\]

Here \( \text{int} \mathcal{B} \) stays for the interior of a set \( \mathcal{B} \).

Following \cite{13, 14}, let’s define the set of normalized immobile indices \( T_{im} \) in problem (I):

\[
T_{im} := \{t \in T : t^\top \mathbf{A}(x)t = 0 \; \forall x \in X\}.
\]

In what follows, the elements of the set \( T_{im} \) are called immobile indices.

The following lemma follows from Lemma 1 and Proposition 1 in \cite{14}.

**Lemma 1** Given the linear copositive problem (I), (i) the Slater condition (6) is equivalent to the emptiness of the set \( T_{im} \), (ii) the normalized immobile index set \( T_{im} \) is either empty or can be represented as a union of a finite number of convex closed bounded polyhedra.
For a vector \( t = (t_k, k \in P)^\top \in \mathbb{R}_+^p \) with \( P := \{1, 2, ..., p\} \), define the sets
\[
P_+(t) := \{k \in P : t_k > 0\}, \quad P_0(t) := P \setminus P_+(t).
\]
Given a set \( B \) and a point \( l = (l_k, k \in P)^\top \in \mathbb{R}_+^p \), denote by \( \rho(l, B) \) the distance between these set and point, \( \rho(l, B) := \min_{\tau \in B} \sum_{k \in P} |l_k - \tau_k| \), and by \( \text{conv}B \) the convex hull of the set \( B \).

Suppose that in problem (1), the normalized immobile index set \( T_{im} \) is non-empty. Consider a finite non-empty subset of \( T_{im} \):
\[
V = \{\tau(i) \in T_{im} : \forall i \in I\}, \quad 0 < |I| < \infty.
\]
For this set, define the following number and sets:
\[
\sigma(V) := \min_{k \in P_+(\tau(i))} \{\tau_k(i), \; i \in I\} > 0, \quad (9)
\]
\[
\Omega(V) := \{t \in T : \rho(t, \text{conv}V) \geq \sigma(V)\}, \quad (10)
\]
\[
\mathcal{X}(V) := \{x \in \mathbb{R}^n : A(x)\tau(i) \geq 0 \forall i \in I; \; t^\top A(x)t \geq 0 \forall t \in \Omega(V)\}. \quad (11)
\]
In [11], the following theorem is proved.

**Theorem 1** Consider problem (1) with the feasible set \( X \). For any subset (8) of the set of normalized immobile indices of this problem, the following equality holds true:
\[
X = \mathcal{X}(V),
\]
where the set \( \mathcal{X}(V) \) is defined in (11).

### 3 Regularization of copositive problems

In this section, first, we remind a known regularization approach developed in [5, 6] for conic optimization problems and based on the concept of the minimal face. We briefly describe how this approach can be applied to linear CoP problems. After, for the copositive problem (1), we present another regularization approach based on the concept of immobile indices and compare the regularized problems obtained using two considered approaches.

#### 3.1 Minimal face regularization

Let us, first, recall the necessary terms and notions.

By definition, a convex subset \( F \) of the cone \( \mathcal{COP}^p \) is its face if for any \( x \in \mathcal{COP}^p, y \in \mathcal{COP}^p \), the inclusion \( x + y \in F \) implies \( x \in F, y \in F \). It is evident that any face of the cone \( \mathcal{COP}^p \) is also a cone.

Given the copositive problem (1) with the feasible set \( X \) presented in (5), let \( F_{min} \) be the smallest (by inclusion) face of \( \mathcal{COP}^p \) containing a set \( D \) defined in terms of the constraints of this problem as follows:
\[
D := \{A(x), \; x \in X\}. \quad (12)
\]
In what follows, the face \( F_{min} \) will be called the minimal face of the optimization problem (1).
Generally speaking, for the copositive problem (1), the approach suggested in [5, 6], is to replace the constraint $A(x) \in \text{COP}^p$ with an equivalent constraint $A(x) \in F_{min}$. The resulting regularized problem takes the form

$$\min_{x \in \mathbb{R}^n} c^T x, \quad \text{s.t. } A(x) \in F_{min}. \quad (13)$$

The dual problem to (13) can be written in the form

$$\max_{U \in S(p)} -A_0 \bullet U, \quad \text{s.t. } A_j \bullet U = c_j \forall j = 1, ..., n; \ U \in F^*_{min}; \quad (14)$$

where $F^*_{min}$ is the dual cone to the cone $F_{min}$.

It is proved in [5, 6], that the constraints of problem (13) satisfy the generalized Slater condition: there exists $\bar{x} \in X$ such that $A(\bar{x}) \in \text{relint } F_{min}$ and hence the duality gap between the dual problems (13) and (14) vanishes. Here relint $B$ stays for the relative interior of a set $B$.

Unfortunately, there is no available information about how to explicitly construct the cones $F_{min}$ and $F^*_{min}$ in a general case and, in particular, in the case of copositive problems.

### 3.2 One-step regularization based on the concept of immobile indices

In our paper [14], for the copositive problem (1), we obtained a regularized dual problem which is different from (14). The construction of this dual is based on the concept of immobile indices and can be considered as one-step regularization since it contains a unique step.

Consider the copositive problem (1). Let $T_{im}$ be the defined in (7) normalized set of immobile indices of this problem. If $T_{im} = \emptyset$, then problem (1) satisfies the Slater condition, which means that it is already regular and no regularization is required.

Now, suppose that $T_{im} \neq \emptyset$. In this case, the Slater condition is not satisfied and the problem is not regular. Let us describe how one can convert problem (1) into a regularized one.

Consider the set $\text{conv} T_{im}$ and the set $W$ of all vertices of $\text{conv} T_{im}$:

$$W := \{t(j), \ j \in J\}, \ 0 < |J| < \infty. \quad (15)$$

Suppose that the elements $t(j), \ j \in J$, of the set $W$ are known. Then we can regularize problem (1) in just one step.

In fact, it follows from Theorem 1 and Lemmas 2 and 3 in [14] that the set $X$ of feasible solutions of the original problem (1) coincides with the set of feasible solutions of the following system:

$$t^T A(x)t \geq 0 \ \forall t \in \Omega(W); \ A(x)t(i) \geq 0 \ \forall i \in J,$$

and the next condition is satisfied:

$$\exists \bar{x} \in X \text{ such that } t^T A(\bar{x})t > 0 \ \forall t \in \Omega(W). \quad (16)$$

Here the set $\Omega(W)$ is defined by the rules (10) with $V = W$. 
Consequently, the original copositive problem (1) is equivalent to the following SIP problem:

\[
\min_{x \in \mathbb{R}^n} c^\top x, \\
\text{s.t.} \quad t^\top A(x) t \geq 0 \quad \forall t \in \Omega(W), \\
A(x) t(i) \geq 0 \quad \forall i \in J.
\]

Problem (17)-(19) can be considered as a regularized primal problem since

- it possesses a finite number of linear inequality constraints (19),
- the first group of constraints, (18), satisfies the Slater type condition (16),
- the set \(\Omega(W)\) is compact.

Let us stress that in problem (17)-(19), the infinite index set \(\Omega(W)\) is obtained by removing the set \(T_{im}\) together with the \(\sigma(W)\)-neighborhood of its convex hull, from the original index set \(T\). Note here that the set \(\Omega(W)\)

- (a) is explicitly constructed by the rules (9), (11), using the finite set \(W = \{t(j), j \in J\}\) of vertices of \(\text{conv} T_{im}\),
- (b) does not contain the set \(\text{conv} T_{im}\),
- (c) may be sufficiently small.

All these properties may be useful for numerical solving the problem (17)-(19).

It is evident that problem (17)-(19) can be written in the equivalent conic form

\[
\min_{x \in \mathbb{R}^n} c^\top x, \quad \text{s.t.} \quad A(x) \in \mathcal{K}_0,
\]

where \(\mathcal{K}_0 := \{ D \in \mathcal{S}(p) : t^\top D t \geq 0 \quad \forall t \in \Omega(W); \quad Dt(j) \geq 0 \quad \forall j \in J\}\).

It can be shown that \(\mathcal{K}_0 \subset \mathcal{COP}^p\).

The dual problem to (20) is as follows:

\[
\max_{U \in \mathcal{S}(p)} -A_0 \cdot U, \quad \text{s.t.} \quad A_j \cdot U = c_j \quad \forall j = 1,\ldots,n; \quad U \in \mathcal{K}_0^*.
\]

In the problem above, \(\mathcal{K}_0^*\) is the dual cone to \(\mathcal{K}_0\) and has the form

\[
\mathcal{K}_0^* = \text{cl}\{ D \in \mathcal{S}(p) : D \in \mathcal{CP}(W) \oplus \mathcal{P}^*\},
\]

where

\[
\mathcal{CP}(W) := \text{conv}\{tt^\top : t \in \Omega(W)\}, \\
\mathcal{P}^* := \{ D \in \mathcal{S}(p) : D = \sum_{j \in J}(\lambda(j)(t(j))^\top + t(j)(\lambda(j))^\top) , \quad \lambda(j) \geq 0 \quad \forall j \in J\}.
\]

Here and in what follows, for given sets \(\mathcal{B}\) and \(\mathcal{G}\), \(\text{cl}\mathcal{B}\) denotes the closure of the set \(\mathcal{B}\) and \(\mathcal{B} \oplus \mathcal{G}\) stays for the Minkowski sum of the corresponding two sets.

Notice that for the pair of dual conic problems (20) and (21), the duality gap is zero.

As it was shown in [14], the cone (22) in problem (21) can be replaced by the following one (which has a more explicit form since it does not contain the closure operator):

\[
\mathcal{K}_0^* := \{ D \in \mathcal{S}(p) : D \in \mathcal{CP}^p \oplus \mathcal{P}^*\},
\]
where \(\mathcal{CP}^p\) denotes the set of completely positive matrices:

\[
\mathcal{CP}^p := \text{conv}\{tt^\top : t \in \mathbb{R}_+^p\},
\]

(23)

and there is no duality gap for problem (20) and its dual problem in the form (21) with \(K_0^*\) replaced by \(K_0^*\).

Note that the cones \(K_0\) and \(K_0^*\) are explicitly described in terms of indices (15) and this is an advantage of the presented here approach over that described in 3.1.

The only drawback of the regularization procedure described here is the following:

"to apply the one-step regularization, one needs to know the finite number of indices (15) which are the vertices of the set \(\text{conv} T_{im}\)."

It is easy to see that the regularized primal problem (20) can be modified as follows:

\[
\min_{x \in \mathbb{R}^n} c^\top x, \quad \text{s.t. } A(x) \in \overline{K}_0,
\]

(24)

where

\[
\overline{K}_0 = \{D \in S(p) : t^\top Dt \geq 0 \ \forall t \in \Omega(W),
\]

\[
e_k^\top Dt(j) = 0 \ \forall k \in P_+(t(j)), \ e_k^\top Dt(j) \geq 0 \ \forall k \in P \setminus P_+(t(j)), \ \forall j \in J\},
\]

\{e_k, k \in P\} is the standard (canonical) basis of the vector space \(\mathbb{R}^p\).

It is evident that \(\overline{K}_0 \subset K_0\) and, as mentioned above, \(K_0 \subset \mathcal{COP}^p\). Hence \(\overline{K}_0 \subset \mathcal{COP}^p\).

To show that these regularizations are themselves deeply connected, let us give an explicit description of the minimal face \(F_{\text{min}}\) in terms of the vertices of the set \(\text{conv} T_{im}\) and the index sets \(M(j), j \in J\), defined as:

\[
M(j) := \{k \in P : e_k^\top A(x)t(j) = 0 \ \forall x \in X\}, \ j \in J.
\]

(25)

The following theorem can be proved (see [11]).

**Theorem 2** Given copositive problem (1), let \(\{t(j), j \in J\}\) be the (finite) set of all vertices of the set \(\text{conv} T_{im}\). Then the minimal face \(F_{\text{min}}\) of this problem can be described in two equivalent forms

\[
F_{\text{min}} = K_{\text{min}}(1) := \{D \in \mathcal{COP}^p : e_k^\top Dt(j) = 0 \ \forall k \in M(j), \ \forall j \in J\}, \ \text{and}
\]

\[
F_{\text{min}} = K_{\text{min}}(2) := \{D \in \mathcal{COP}^p : e_k^\top Dt(j) = 0 \ \forall k \in M(j),
\]

\[e_k^\top Dt(j) \geq 0 \ \forall k \in P \setminus M(j), \ \forall j \in J\}.
\]

Now, having described the minimal face \(F_{\text{min}}\) via immobile indices, we can compare the regularized problems (13), (20), and (24) in more detail.

The regularized problem (13) is formulated using the facial reduction approach to the copositive problem (1) and the regularized problems (20) and (24) are obtained using the immobile indices of this problem. The difference between these three problems is that in problem (13), the constraint set is determined by the minimal face \(F_{\text{min}}\), while the constraints of problem (20) are formulated with the help of the cone \(K_0\), and the constraints of problem (24) use the cone...
It should be noticed that the minimal face \( F_{\min} \) and the cones \( K_0 \) and \( \overline{K}_0 \) satisfy the inclusions
\[
F_{\min} \subset \overline{K}_0 \subset K_0.
\]
At the same time, the cones \( F_{\min} \) and \( \overline{K}_0 \) are faces of the cone of copositive matrices \( \mathcal{COP}^p \), while the cone \( K_0 \) is not, in general. One can show that \( \overline{K}_0 \) is an exposed face while the face \( F_{\min} \) is not, in general.

For each of the mentioned above conic problems, we face certain challenges caused by the troubles connected with the concrete construction of the respective cones. Thus, for example, for the copositive problem (1), the following difficulties should be mentioned:

- to define the cones \( K_0 \) and \( \overline{K}_0 \), the elements \( t(j), j \in J \), of the finite set of indices (15) should be known;
- as far as we know, there are no explicit procedures of constructing the minimal face \( F_{\min} \) and its dual cone \( F_{\min}^* \).

Theorem 2 shows how the minimal face \( F_{\min} \) can be represented in the form of the cones \( K_{\min}(1) \) and \( K_{\min}(2) \) via immobile indices. Notice that to construct these cones, one has to find not only the set of indices (15) but also the corresponding sets \( M(j), j \in J \), defined in (25).

As mentioned above, regularity is an important property of optimization problems. As a rule, the regularity of copositive problems is characterized by the Slater condition. In this regard, it is important to note that the regularized problem (13) satisfies the generalized Slater condition while the obtained here regularized problems (20) and (24) satisfy the Slater type condition (16). This difference can be important for further study of linear CoP problems, as well as for the development of stable numerical methods for them.

4 Iterative algorithms for regularization of linear copositive problems

In section 3, we considered general schemes of two theoretical methods that allowed us to obtain regularizations of the linear copositive problem (1). In each of these schemes, we meet some difficulties associated with explicit representations of the respective "regularized" feasible cones and their dual ones. In this section, we consider and compare two different regularization approaches aimed to overcome these difficulties using algorithmic procedures.

4.1 Waki and Muramatsu’s facial reduction algorithm

In [24], for linear conic problems, a regularization algorithm was proposed by Waki and Muramatsu. This algorithm can be considered as the Facial Reduction Algorithm (FRA) from [5, 6] applied to linear conic problems in finite-dimensional spaces.

Let us describe the algorithm from [24] for the linear copositive problem (1) with the matrix constraint function \( A(x) \) defined in (2). Remind that here we consider that problem (1) is feasible. Then, according to Remark 1 we can assume that \( A_0 \in \mathcal{COP}^p \).

Denote
\[
\text{Ker} A := \{ D \in S(p) : A_j \bullet D = 0 \ \forall j = 0, 1, \ldots, n \}.
\]
As above, let \( \mathcal{F}^* \) denote the dual cone of a given cone \( \mathcal{F} \).

For a given feasible copositive problem \((\mathcal{CP})\), starting with \( \mathcal{CP}^p \), the Waki and Muramatsu’s algorithm repeatedly finds smaller faces of \( \mathcal{CP}^p \) until it stops with the minimal face \( \mathcal{F}_{\text{min}} \).

**Waki and Muramatsu’s FRA for the copositive problem \((\mathcal{CP})\)**

**Step 1:** Set \( i := 0 \) and \( \mathcal{F}_0 := \mathcal{CP}^p \).

**Step 2:** If \( \text{Ker} \mathcal{A} \cap \mathcal{F}_i^* \subset \text{span}\{Y_1, ..., Y_i\} \), then STOP: \( \mathcal{F}_{\text{min}} = \mathcal{F}_i \).

**Step 3:** Find \( Y_{i+1} \in \text{Ker} \mathcal{A} \cap \mathcal{F}_i^* \setminus \text{span}\{Y_1, ..., Y_i\} \).

**Step 4:** Set \( \mathcal{F}_{i+1} := \mathcal{F}_i \cap \{Y_{i+1}\}^\perp \) and \( i := i + 1 \), and go to step 2.

The description of the algorithm is very simple but, in practice, its implementation presents serious difficulties which arise on step 2 and especially on step 3. As the matter of fact, in the case of the copositive problem \((\mathcal{CP})\), the fulfillment of step 3 is hard already on the first two iterations.

Let us consider the initial iteration when \( i = 0 \). On step 3, one has to find a matrix \( Y_1 = \sum_{i \in I_1} t(i)(t(i))^\top \), \( t(i) \geq 0 \), \( t(i) \neq 0 \) \( \forall i \in I_1 \), \( 0 < |I_1| \leq p(p+1)/2 \), and the condition \( \sum_{i \in I_1} (t(i))^\top A_j t(i) = 0 \) \( \forall j = 0, 1, ..., n \), has to be satisfied.

At the next iteration \( (i = 1) \), one is looking for a matrix \( Y_2 \) such that

**C1:** \( Y_2 \in \mathcal{F}_1^* = \text{cl}\{D \in S(p) : D \in \mathcal{CP}^p \oplus \alpha Y_1, \alpha \in \mathbb{R}\} \),

**C2:** \( Y_2 \notin \text{span}\{Y_1\} \),

**C3:** \( A_j \cdot Y_2 = 0 \) \( \forall j = 0, 1, ..., n \).

The first difficulty arises when trying to satisfy the condition **C1**, as there is no explicit description of the set \( \mathcal{F}_1^* \). Notice that this set is defined using the closure operator, this operator being essential for the definition of \( \mathcal{F}_1^* \). Therefore, in general, for a matrix \( Y_2 \) satisfying the condition **C1**, it may happen that \( Y_2 \notin \{D \in S(p) : D \in \mathcal{CP}^p \oplus \alpha Y_1, \alpha \in \mathbb{R}\} \).

In \([24]\), there is also no any indication of how to find a matrix \( Y_2 \) satisfying the conditions **C2** and **C3**. Notice that the fulfillment of these conditions is a non-trivial task as well.

Thus, we can state that although the reported in \([24]\) FRA is an easy-to-describe method, its practical implementation is not constructively described, which makes it difficult to apply. There is no information concerning which form should have the matrix \( Y_i \) at the \( i \)-th iteration \( (i \geq 1) \) of the algorithm and how to meet the conditions **C1** - **C3** for it.

### 4.2 A regularization based on the immobile indices

Here we will describe and justify a different algorithm for regularization of the copositive problem \((\mathcal{CP})\). This algorithm has a similar structure to the Waki and Muramatsu’s FRA considered in \([14]\) but is based on the concept of immobile indices and described in more detail, being, therefore, more constructive. Note from the outset that although our algorithm exploits the properties of the set of immobile indices, it does not require the initial knowledge of either this set or the vertices of its convex hull.
4.2.1 Algorithm REG-LCoP (REGularization of Linear Copositive Problems)

**Iteration \# 0.** Given the copositive problem in the form (1), consider the following *regular* SIP problem:

\[
SIP_0: \quad \min_{(x, \mu) \in \mathbb{R}^{n+1}} \mu, \text{ s.t. } t^\top A(x) t + \mu \geq 0 \ \forall t \in T,
\]

with the index set \( T \) defined in (1).

If there exists a feasible solution \((\bar{x}, \bar{\mu})\) of this problem with \(\bar{\mu} < 0\), then set \(m_* := 0\) and go to the Final step.

Otherwise the vector \((x = 0, \mu = 0)\) is an optimal solution of the problem \((SIP_0)\).

It should be noticed that in the problem \((SIP_0)\), the index set \( T \) is compact, and the constraints satisfy the Slater condition. Hence, (see e.g. [1]), it follows from the optimality conditions for the vector \((x = 0, \mu = 0)\) that there exist indices and numbers \(\tau(i) \in T, \gamma(i) > 0 \ \forall i \in I_1, \ |I_1| \leq n + 1,\) such that \(\sum_{i \in I_1} \gamma(i)(\tau(i))^\top A_j(\tau(i)) = 0 \ \forall j = 0, 1, ..., n; \sum_{i \in I_1} \gamma(i) = 1.\)

It follows from the relations above that \(I_1 \neq \emptyset\) and \(\tau(i) \in T_{im} \subset T \ \forall i \in I_1,\) and hence \(e_k^\top A(x)(\tau(i)) = 0 \ \forall k \in P_+(t(i)), \forall i \in I_1, \forall x \in X.\) Set \(L_1(i) := P_+(\tau(i)), i \in I_1,\) and go to the next iteration.

**Iteration \# \(m, \ m \geq 1.** By the beginning of the iteration, we have indices and sets \(\tau(i), L_m(i), i \in I_m,\) such that

\[
\tau(i) \in T_{im}, \ P_+(\tau(i)) \subset L_m(i) \subset P, \ e_k^\top A(x)(\tau(i)) = 0 \ \forall k \in L_m(i), \forall x \in X, \forall i \in I_m. \quad (26)
\]

Consider a SIP problem

\[
SIP_m: \quad \min_{(x, \mu) \in \mathbb{R}^{n+1}} \mu, \quad \text{s.t. } e_k^\top A(x)(\tau(i)) = 0 \ \forall k \in L_m(i); \ e_k^\top A(x)(\tau(i)) \geq 0 \ \forall k \in P \setminus L_m(i), \ \forall i \in I_m,
\]

\[
t^\top A(x) t + \mu \geq 0 \ \forall t \in \Omega(W_m),
\]

where \(W_m := \{\tau(i), i \in I_m\},\) the set \(\Omega(W_m)\) is constructed by the rules (9), (10) with \(V = W_m.\)

Since \(W_m\) is a subset of the set of immobile indices of problem (1), then it follows from Theorem 11 and the equalities in (26) that \(X(W_m) = X.\)

Notice that by the definition of the set \(\Omega(W_m),\) it holds:

\[
\rho(t, \text{conv}W_m) \geq \sigma(W_m) > 0 \ \forall t \in \Omega(W_m).
\]

In the problem \((SIP_m),\) the index set \(\Omega(W_m)\) is compact and the constraints satisfy the following Slater type condition:

\[
\exists(\bar{x}, \bar{\mu}) \text{ such that } e_k^\top A(\bar{x})(\tau(i)) = 0 \ \forall k \in L_m(i); \ e_k^\top A(\bar{x})(\tau(i)) \geq 0 \ \forall k \in P \setminus L_m(i), \ \forall i \in I_m,
\]

\[
t^\top A(\bar{x}) t + \bar{\mu} > 0 \ \forall t \in \Omega(W_m).
\]

Hence, this problem is *regular.*

If problem \((SIP_m)\) admits a feasible solution \((\bar{x}, \bar{\mu})\) with \(\bar{\mu} < 0,\) then STOP and go to the Final step with \(m_* := m.\)
Suppose now that the problem is regular. Note that by construction, \( X(1) \) and can be considered as its regularization since \( 0 = 0.0 \). Observe that by Theorem 1, the found vector \( \bar{\mu} < \) copositive problem (1).

It follows from (29) that the algorithm \textbf{DAM} to the data (27), the following conditions are met:

\[
\sum_{i \in \Delta I_m} \gamma(i)(\tau(i))^\top A_j \tau(i) + 2 \sum_{i \in I_m}(\lambda^m(i))^\top A_j \tau(i) = 0 \quad \forall j = 0, 1, ..., n;
\]

\[
\gamma(i) > 0 \quad \forall i \in \Delta I_m; \quad \lambda^m_k(i) \geq 0 \quad \forall k \in P \setminus L_m(i), \quad \forall i \in I_m.
\] (28)

Here and in what follows, without loss of generality, we suppose that \( \Delta I_m \cap I_m = \emptyset \). Moreover, applying the described in [12] procedure \textbf{DAM} to the data (27), it is possible to ensure that the following conditions are met:

\[
P_0(\tau(i)) \cap P_+(\tau(j)) \neq \emptyset \quad \forall i \in \Delta I_m, \quad \forall j \in I_m.
\] (29)

Let us set \( \Delta L(i) := \{ k \in P \setminus L_m(i) : \lambda^m_k(i) > 0 \}, \quad i \in I_m, \)

\[
L_{m+1}(i) := L_m(i) \cup \Delta L(i), \quad i \in I_m; \quad L_{m+1}(i) := P_+(\tau(i)), \quad i \in \Delta I_m.
\]

It follows from (28) that \( e_k^\top \mathcal{A}(x) \tau(i) = 0 \quad \forall k \in \Delta L(i), \quad \forall i \in I_m, \) and \( \tau(i) \in T_{im} \quad \forall i \in \Delta I_m \). The last inclusions imply the equalities \( e_k^\top \mathcal{A}(x) \tau(i) = 0 \quad \forall k \in P_+(\tau(i)), \quad \forall i \in \Delta I_m \).

Go to the next iteration \( \#(m+1) \) with the new data

\[
\tau(i), \quad L_{m+1}(i), \quad i \in I_{m+1} := I_m \cup \Delta I_m.
\] (30)

**Final step.** It follows from (29) that the algorithm \textbf{REG-LCoP} runs a finite number \( m_* \) of iterations. Therefore, for some \( m_* \geq 0 \), the problem \( (SIP_{m_*}) \) has a feasible solution \( (\bar{x}, \bar{\mu}) \) with \( \bar{\mu} < 0 \). Observe that by Theorem 1 the found vector \( \bar{x} \) is a feasible solution of the original copositive problem (1).

If \( m_* = 0 \), then the constraints of problem (1) satisfy the Slater condition with \( \bar{x} \), and hence the problem is regular.

Suppose now that \( m_* > 0 \). Consider problem

\[
\min_{x \in \mathbb{R}^n} c^\top x,
\]

\[
\text{s.t.} \quad e_k^\top \mathcal{A}(x) \tau(i) = 0 \quad \forall k \in L_{m_*}(i), \quad e_k^\top \mathcal{A}(x) \tau(i) \geq 0 \quad \forall k \in P \setminus L_{m_*}(i), \quad \forall i \in I_{m_*}, \quad t^\top \mathcal{A}(\bar{x}) t \geq 0 \quad \forall t \in \Omega(W_{m_*})
\]

where the sets \( W_{m_*} = \{ \tau(i), i \in I_{m_*} \} \) and \( \Omega(W_{m_*}) \) are the same as in the problem \( (SIP_{m_*}) \). Note that by construction, \( \mathcal{X}(W_{m_*}) = X \). Hence the problem above is equivalent to problem (1) and can be considered as its regularization since

- it has a finite number of linear equality/inequality constraints,
- by construction, \( t^\top \mathcal{A}(\bar{x}) t > 0 \quad \forall t \in \Omega(W_{m_*}) \) for some \( \bar{x} \in X \).

The algorithm is described.

**Remark 2** In the described above algorithm \textbf{REG-LCoP}, it is assumed that \( X \neq \emptyset \). It is easy to modify the algorithm so that this assumption is removed.
4.2.2 On the comparison of the algorithms

To give another interpretation of the algorithm REG-LCoP and to better trace the compliance of the algorithm REG-LCoP to the Waki and Muramatsu’s FRA from [24] (presented in [1.1]), let us perform some additional constructions at the iterations of the algorithm REG-LCoP.

At the end of Iteration \# 0, having data \( \tau(i) \), \( \gamma(i) \), \( L_1(i) \), \( i \in I_1 \), let us set

\[
F_0 := \mathcal{COP}^p, \quad Y_1 := \sum_{i \in I_1} \gamma(i) \tau(i)(\tau(i))^\top, \quad F_1 := F_0 \cap \{Y_1\}^\perp.
\]

Notice here that, by construction,

\[
Y_1 \neq \emptyset_p, \quad Y_1 \in \text{Ker}A, \quad Y_1 \in F_0^* = \mathcal{C}^p,
\]

\[
F_1 := F_0 \cap \{Y_1\}^\perp = \{D \in \mathcal{COP}^p : D \cdot Y_1 = 0\} = \{D \in \mathcal{COP}^p : (\tau(i))^\top D\tau(i) = 0 \forall i \in I_1\}
\]

\[
= \{D \in \mathcal{COP}^p : e_k^\top D\tau(i) = 0 \forall i \in L_1(i), \ e_k^\top D\tau(i) \geq 0 \forall i \in P \setminus L_1(i), \forall i \in I_1\},
\]

where \( \emptyset_p \) is the \( p \times p \) null matrix.

Consider Iteration \# \( m \), \( 1 \leq m \leq m_* \). By the beginning of the iteration, we have a cone \( F_m = F_{m-1} \cap \{Y_m\}^\perp \) that can be described as follows:

\[
F_m = \{D \in \mathcal{COP}^p : e_k^\top D\tau(i) = 0 \forall k \in L_m(i), \ e_k^\top D\tau(i) \geq 0 \forall k \in P \setminus L_m(i), \forall i \in I_m\}. \quad (31)
\]

At the end of this iteration, we have new data \( (30) \) and numbers \( \gamma(i), i \in \Delta I_m \). Let us set

\[
Y_{m+1} := \sum_{i \in \Delta I_m} \gamma(i) \tau(i)(\tau(i))^\top + \sum_{i \in I_m} [\tau(i)(\lambda^m(i))^\top + \lambda^m(i)(\tau(i))^\top]. \quad (32)
\]

From the equations in \( (28) \), we conclude: \( Y_{m+1} \in \text{Ker}A \). From \( (31) \), it follows:

\[
F_m^* = \text{cl}\{D \in S(p) : D \in \mathcal{C}^p \oplus \mathcal{P}_m^*\},
\]

\[
\mathcal{P}_m^* := \{D \in S(p) : D = \sum_{i \in I_m} [\tau(i)(\lambda(i))^\top + \lambda(i)(\tau(i))^\top], \ \lambda_k(i) \geq 0 \forall k \in P \setminus L_m(i), \forall i \in I_m\}.
\]

Hence, by construction, \( Y_{m+1} \in F_m^* \).

Consider the cone \( F_{m+1} := F_m \cap \{Y_{m+1}\}^\perp \) and show that it can be described as follows:

\[
F_{m+1} = \{D \in \mathcal{COP}^p : e_k^\top D\tau(i) = 0 \forall k \in L_{m+1}(i), \ e_k^\top D\tau(i) \geq 0 \forall k \in P \setminus L_{m+1}(i), \forall i \in I_{m+1}\}. \quad (33)
\]

In fact, it follows from \( (32) \) that the equality \( D \cdot Y_{m+1} = 0 \) can be rewritten in the form

\[
0 = D \cdot Y_{m+1} = \sum_{i \in \Delta I_m} \gamma(i)(\tau(i))^\top D\tau(i) + 2 \sum_{i \in I_m} (\lambda^m(i))^\top D\tau(i),
\]

where \( \gamma(i) > 0 \forall i \in \Delta I_m; \ \lambda^m_k(i) \geq 0 \forall k \in P \setminus L_m(i), \forall i \in I_m \).

Taking into account \( (31) \) and the relations above, we conclude that for \( D \in F_m \), the equality \( D \cdot Y_{m+1} = 0 \) implies the equalities

\[
(\tau(i))^\top D\tau(i) = 0 \forall i \in \Delta I_m, \ e_k^\top D\tau(i) = 0 \forall k \in \Delta L(i), \forall i \in I_m.
\]
Notice that the relations $D \in \mathcal{COP}^p$, $(\tau(i))^\top D\tau(i) = 0$, $\tau(i) \geq 0 \forall i \in \Delta I_m$, imply

$$e_k^\top D\tau(i) = 0 \forall k \in P_+(\tau(i))$$

and

$$e_k^\top D\tau(i) \geq 0 \forall k \in P \setminus P_+(\tau(i)), \forall i \in \Delta I_m.$$ (34)

Representation (33) follows from (31) and (34).

The constructed by rules (32) and (33) matrices and cones

$$Y_m, F_m, m = 0, 1, ..., m_*,$$ (35)

satisfy the following relations:

1. $Y_m \in F_{m-1}^* \forall m = 1, ..., m_*$, $Y_0 = \mathcal{O}_p$: (I)
2. $Y_m \in \text{Ker}A \forall m = 1, ..., m_*$: (II)
3. $F_m = F_{m-1} \cap \{Y_m\}^\perp \forall m = 1, ..., m_*$, $F_0 = \mathcal{COP}^p$: (III)

Now we see that the algorithm REG-LCoP allows one to get a more clear description of the structure of the matrices $Y_m, m = 1, ..., m_*$, satisfying conditions (I) – (III), and quite constructive rules of their formation:

for a given $m$, the matrix $Y_m$ has a form (32) and is built on the basis of the optimality conditions for the feasible solution $(x = 0, \mu = 0)$ in the corresponding regular SIP problem ($SIP_m$).

As it was shown in subsection 4.1 at each iteration, the Waki and Muramatsu’s FRA produces a set of matrices and cones (33) satisfying the conditions (I) – (III), and the condition

$$Y_m \notin \text{span}\{Y_0, Y_1, ..., Y_{m-1}\} \forall m = 1, ..., m_* - 1.$$ (IV)

On the other hand, the described in subsection 4.2 algorithm REG-LCoP at each iteration produces a set of matrices and cones (35) satisfying the conditions (I) – (III) but not necessarily the condition (IV).

Since in the algorithm REG-LCoP, the fulfillment of the condition (IV) is not guaranteed at each iteration, if compare this algorithm with the Waki and Muramatsu’s FRA, at the first glance it may seem that, in general, the number of iterations executed by the algorithm REG-LCoP is larger. Such an impression is caused by the fact that in 4.2.1 we described in more detail all the steps of the algorithm and explicitly indicated all the computations carried out at each iteration. As for the Waki and Muramatsu’s FRA, its iterations are described only in general terms.

In what follows, we set out a modification of the algorithm REG-LCoP, where the number of iterations is reduced and it is guaranteed that all conditions (I) – (IV) are satisfied on each core iteration. This modification is formal, being essentially another way of the iterations’ numbering. The real number of the calculations on the steps of this modified algorithm is the same as on the iterations of the original one.

### 4.2.3 A compressed modification of the algorithm REG-LCoP

Consider the algorithm REG-LCoP presented in 4.2.1. Evidently, one can reduce the number of iterations of the algorithm if squeeze into just one iteration that iterations of the algorithm which change the description of the dual cone $F_m^*$, but do not change the cone $F_m$ itself. In
other words, we will only move to the next core iteration when all conditions (I) – (IV) are satisfied. Formally, such a procedure can be described as follows.

Suppose that the algorithm REG-LCoP has constructed matrices and cones (35), satisfying the properties (I) – (III) and let $m_s > 0$. Denote by $m_s \in \{0, 1, ..., m_s - 1\}$, $s = 0, 1, ..., s_s$, the iterations’ numbers such that

\[
m_0 := 0, \ m_s < m_{s+1} \ \forall s = 0, 1, ..., s_s - 1; \ m_{s+1} = m_s, \]
\[
Y_{m_s+1} \not\in \text{span}\{Y_0, Y_1, ..., Y_{m_s}\} \ \forall s = 0, 1, ..., s_s - 1; \]
\[
Y_{m_s+1+i} \in \text{span}\{Y_0, Y_1, ..., Y_{m_s+i}\} \ \forall i = 1, ..., m_{s+1} - m_s - 1, \ \forall s = 0, 1, ..., s_s - 1.
\]

Here $s_s$ denotes the number of iterations for which the conditions above are met. Notice that the set \{l, l + 1, ..., w\} is considered empty if $w < l$.

In other words, the condition (IV) is satisfied only for $m \in \{m_s + 1, s = 0, 1, ..., s_s - 1\}$ and, possibly, for $m = m_s$. Set

\[
Y_0 := Y_0, \ \tilde{F}_0 := \mathcal{F}_0, \ Y_{s+1} := Y_{m_s+1}, \ \tilde{F}_{s+1} := \mathcal{F}_{m_s+1} \ \forall s = 0, 1, ..., s_s.
\]

It is easy to check that the following conditions hold true:

\[
Y_s \in \mathcal{F}_{s-1}^*, \ Y_s \in \text{Ker}\mathcal{A}, \ \mathcal{F}_s = \mathcal{F}_{s-1} \cap \{Y_s\}^\perp \ \forall s = 1, ..., s_s + 1;
\]
\[
Y_s \not\in \text{span}\{Y_0, Y_1, ..., Y_{s-1}\} \ \forall s = 1, ..., s_s.
\]

Thus, after the described above squeezing, we get $s_s$ core iterations of the modified algorithm. It follows from the conditions above that $s_s \leq \dim(\text{Ker}\mathcal{A})$.

Notice that for any $s = 0, 1, ..., s_s - 1$, the iterations of the algorithm REG-LCoP having the numbers $m_s + 1 + i$, where $i = 1, ..., m_{s+1} - m_s - 1$ (the compressed iterations), are not useless. They can be considered as the steps of a regularization procedure for the cone $\mathcal{F}_{m_s+1}$ at the current core iteration $# s$. At each of these iterations, we reformulate the cone $\mathcal{F}_{m_s+1}$ in a new equivalent form. This additional information allows us to improve (make more regular) the representation of the cone $\mathcal{F}_{m_s+1}$ and get a more explicit and useful description of its dual cone $\mathcal{F}^*_{m_s+1}$.

### 4.2.4 A short discussion on the algorithms considered in this section

By analyzing and comparing the iterative algorithms presented above, we can draw the following conclusions.

1. The Waki and Muramatsu’s facial reduction algorithm from [24], reformulated for copositive problems in subsection 4.1, is very simple in the description and runs no more than $\dim(\text{Ker}\mathcal{A})$ iterations. But this algorithm is more conceptual than constructive since it does not provide any information about the structure of the matrix $Y_m$ and the cone $\mathcal{F}^*_m$ at its $m$-th iteration. Moreover, it is not explained in [24] how to fulfill steps 2 and 3 at each iteration.

2. The algorithm REG-LCoP proposed in subsection 4.2 also runs a finite number of iterations. This algorithm is described in all details and justified. The quite constructive rules for calculating the matrix $Y_m$ satisfying the condition $Y_m \in \mathcal{F}^*_m$, are presented using
the information available at the Iteration \#m of this algorithm. These rules are derived from the optimality conditions for the optimal solution \((x = 0, \mu = 0)\) of the regular problem \((SIP_m)\).

Notice that it is possible to develop a modification of the algorithm \text{REG-LCoP} which runs no more than \(2n\) iterations.

3. Finally, to show that the described in 4.2.1 algorithm \text{REG-LCoP} is not worse (by the number of iterations) than the FRA from the subsection 4.1, we presented a compressed modification of the algorithm \text{REG-LCoP}. This modification consists of no more than \(\dim(\text{Ker}A)\) iterations as well as the algorithm from subsection 4.1.

5 Conclusions

The main contribution of the paper is that, based on the concept of immobile indices, previously introduced for semi-infinite optimization problems, we suggested new methods for regularization of copositive problems. The algorithmic procedure of regularization of copositive problems is described in the form of the algorithm \text{REG-LCoP} and is compared with the facial reduction approach based on the minimal cone representation. We show that, when applied to the linear CoP problem \((\ref{1})\), the algorithm \text{REG-LCoP} possesses the same properties as the FRA suggested by Waki and Muramatsu in \([21]\), but its iterations are explicit, described in more detail and hence more constructive.

The described in the paper algorithms are useful for the study of convex copositive problems. In particular, for the linear copositive problem, they allow to

\begin{itemize}
  \item formulate an equivalent (regular) semi-infinite problem which satisfies the Slater type regularity condition and can be solved numerically;
  \item prove new optimality conditions without any CQs;
  \item develop strong duality theory based on an explicit representation of the "regularized" feasible cone and the corresponding dual (such as, e.g. the Extended Lagrange Dual Problem suggested for SDP by Ramana et al. in \([21]\)).
\end{itemize}

The described in the paper regularization approach is novel and rather constructive. It is important to stress that no constructive regularization procedures are known for linear copositive problems.
