Received: 22 May 2015 / Accepted: 31 August 2015

Abstract This paper investigates the potential for stabilizing an inverted pendulum without electric devices, using gravitational potential energy. We propose a wheeled mechanism on a slope, specifically, a wheeled double pendulum, whose second pendulum transforms gravity force into braking force that acts on the wheel. In this paper, we derive steady-state equations of this system and conduct nonlinear analysis to obtain parameter conditions under which the standing position of the first pendulum becomes asymptotically stable. In this asymptotically stable condition, the proposed mechanism descends the slope in a stable standing position, while dissipating gravitational potential energy via the brake mechanism. By numerically continuing the stability limits in the parameter space, we find that the stable parameter region is simply connected. This implies that the proposed mechanism can be robust against errors in parameter setting.

Keywords Wheeled inverted pendulum · Passive control · Gravity · Friction · Asymptotic stabilization

1 Introduction

Electric and electronic control devices are indispensable for a variety of modern technologies. However, these technologies typically become useless during massive power outages such as those caused by natural or other disasters. In this paper, we consider a non-electrified alternative control method to stabilize an inverted pendulum using gravitational potential. Our proposed mechanism is a wheeled inverted pendulum that descends a slope. The brake mechanism of our proposed mechanism transforms gravity force into friction force between the pendulum and the wheel. This friction produces a restoring force by which the pendulum is asymptotically stabilized in a standing position.

Approaches similar to ours can be found in the field of passive dynamic walking, pioneered by McGeer [1], in which two-legged mechanisms are designed to stably walk down a slope that consume only gravitational potential energy. Extensive studies have been reported on the passive dynamic walking, including experimental development of passive walkers [1–3] and nonlinear analyses of passive dynamic walking based on simplified models [4–6]. Early insights into the use of such passivity can also be found in the study of passive gravity-gradient attitude stabilization [7–10] wherein the alignment of one axis of a satellite along the earth’s local vertical direction was achieved without the use of active control elements.

On the other hand, the wheeled inverted pendulum has attracted significant attention in the fields of control engineering and robotics. Because of the applications of wheeled inverted pendulums in personal mobility devices, including the Segway® [11], methods for controlling wheeled inverted pendulums have been developed via approaches such as partial feedback linearization [12], inclined surface control [13], sliding-mode velocity control [14], neuro-fuzzy-based control [15], and robust control based on a quasi-linear parameter-varying model [16]. Not surprisingly, these studies implied the use of electric devices.
In this paper, we merge concepts from passive dynamic walking and studies of the wheeled inverted pendulum to derive our new mechanical design for the non-electrified stabilization of a wheeled inverted pendulum. As stated above, we propose a wheeled double pendulum mechanism, whose second pendulum transforms gravity force into braking force that acts on the wheel. To investigate the dynamic stabilities of this newly proposed mechanism, we start with deriving a nonlinear analytical model of the mechanism to examine the stabilities of its steady states. Three types of critical points arise in the analytical model. These critical points are analytically characterized and numerically continued in the parameter space to obtain stability limits for the steady standing motions. It is found that the stability of the proposed mechanism is limited by Hopf bifurcation and vanishing external resistance on the wheel.

2 Wheeled inverted pendulum with friction control

We propose a wheeled inverted pendulum with friction control, as shown in Fig. 1, that comprises 1) a wheel placed on a slope without slipping, 2) a double pendulum suspended on the wheel axis, and 3) a friction control mechanism that generates a braking force on the wheel proportional to the angle between the first and second pendulums. Hereinafter, we refer to this model as a friction-controlled wheeled inverted pendulum (FCWIP).

Configuration of the FCWIP can be described by a three-dimensional generalized coordinate: \( \theta = (\theta_1, \theta_2, \theta_3)^T \),

\[
\begin{align*}
\theta_1 &= \text{the rotational angle of the wheel}, \\
\theta_2 &= \text{the absolute slant angle of the first pendulum}, \\
\theta_3 &= \text{the relative angle of the second pendulum from the first pendulum}.
\end{align*}
\]

where \( \theta_1 \) is the rotational angle of the wheel, \( \theta_2 \) is the absolute slant angle of the first pendulum, and \( \theta_3 \) is the relative angle of the second pendulum from the first pendulum. In addition, we consider the corresponding generalized force:

\[
\mathbf{T} = (T_1, T_2, T_3)^T,
\]

where \( T_i \) is a torque acting on \( \theta_i \).

### 2.1 Wheeled double pendulum

Unless the friction control mechanism (or \( \mathbf{T} \)) is specified, the FCWIP in Fig. 1 is simply a wheeled double pendulum whose Lagrangian is given by

\[
\begin{align*}
L := \mathbf{T} - \mathbf{U} :& \quad \mathbf{T} := \frac{1}{2} \dot{\theta}_1^2(Q_1 r + I_1) + \frac{1}{2} \dot{\theta}_2^2\{ -2Q_3 \dot{r} \cos(\theta_3) + Q_2 + I_2 \} \\
&+ \frac{1}{2} \dot{\theta}_3^2(Q_3 w_G + I_3) + \dot{\theta}_1 \dot{\theta}_3 Q_3 \{ w_G - I \cos(\theta_3) \} \\
&+ \dot{\theta}_1 \dot{\theta}_2 \{ -Q_3 \dot{r} \cos(\alpha - \theta_2 - \theta_3) + Q_4 \dot{r} \cos(\alpha - \theta_2) \} \\
&- \dot{\theta}_1 \dot{\theta}_3 Q_4 \dot{r} \cos(\alpha - \theta_2 - \theta_3), \\
\mathbf{U} := -g \{ Q_3 \cos(\theta_2 + \theta_3) - Q_4 \cos(\theta_2) + \theta_1 Q_1 \sin(\alpha) \},
\end{align*}
\]

with

\[
\begin{align*}
Q_1 &= (m_1 + m_2 + m_3) \dot{r}, \\
Q_2 &= m_3 l_G^2 + m_3 (w_G^2 + \dot{r}^2), \\
Q_3 &= m_3 w_G, \\
Q_4 &= m_2 l_G + m_3 l.
\end{align*}
\]

where the physical parameters are listed in Table 1.
On substituting $L$ into Lagrange’s equations with the generalized force $T$, we obtain the equations of motion of the wheeled double pendulum as

$$M\ddot{\theta} = F + T,$$

with

$$M^T = M, \quad M_{11} = Q_1r + I_1,$$

$$M_{12} = -Q_3r\cos(\alpha - \theta_2 - \theta_3) + Q_4r\cos(\alpha - \theta_2),$$

$$M_{13} = -Q_3r\cos(\alpha - \theta_2 - \theta_3),$$

$$M_{22} = -2Q_3l\cos(\theta_3) + Q_2 + I_2,$$

$$M_{23} = Q_3\{w_G - l\cos(\theta_3)\}, \quad M_{33} = Q_3w_G + I_3,$$

and

$$F_1 = Q_3r(\dot{\theta}_2 + \dot{\theta}_3)^2\sin(\alpha - \theta_2 - \theta_3) - Q_4r\dot{\theta}_3^2\sin(\alpha - \theta_2) + gQ_1\sin(\alpha),$$

$$F_2 = -Q_3\dot{\theta}_3(2\dot{\theta}_2 + \dot{\theta}_3)\sin(\theta_3) - g\{Q_3\sin(\theta_2 + \theta_3) - Q_4\sin(\theta_2)\},$$

$$F_3 = Q_3\dot{\theta}_3^2\sin(\theta_3) - gQ_3\sin(\theta_2 + \theta_3),$$

where $M_{ij}$ represents the $(i, j)$ component of the matrix $M$ and $F_i$ is the $i$th component of the vector $F$.

### 2.2 Friction control mechanism

Next, we introduce a friction control mechanism (FCM) into the wheeled double pendulum by specifying $T$ as follows.

Let $z$ be a displacement of the brake rod outputted from the cam mechanism, as shown in Fig. 1, and suppose that the cam function $z(\theta_3)$ is given as a linear function:

$$z = z(\theta_3) := \rho(\theta_3 - \eta), \quad \dot{z} = \rho\dot{\theta}_3 \tag{10}$$

where $\rho$ is a cam ratio and $\eta > 0$ is an offset angle. Accordingly, the follower is expected to follow both the positive and negative rotation of the cam.

Then, we consider a brake mechanism, as shown in Fig. 2. In this mechanism, a pad (in light gray) is bonded on a brake rod (in dark gray) and sandwiched between the fixed base on the first pendulum and the brake disk without clearance at $z = 0$. We refer to the lower half of the pad as a brake pad and the upper half as a dummy. The dummy pad has no function in terms of braking but is assumed to have the same mechanical property as the brake pad.

Thus, the brake pad touches the brake disk when $z \geq 0$ but is separated from the disk when $z < 0$. We assume that the brake rod receives a continuous reaction force from the pads in the following form:

$$R = R(z, \dot{z}) := -(k_bz + c_b\dot{z})$$

$$= -\rho\{k_b(\theta_3 - \eta) + c_b\dot{\theta}_3\}, \tag{11}$$

where $c_b$ and $k_b$ are viscoelastic coefficients of the pad.

The reaction force $R$ produces a torque on $\theta_3$ as a generalized force $F_{\theta_3}$ on $\theta_3$, given by

$$F_{\theta_3} = \frac{\partial z}{\partial \theta_3}R(z, \dot{z}) = \rho R(z, \dot{z}). \tag{12}$$

At the same time, we assume that $R$ causes a Coulomb friction force between the brake pad and the brake disk. This force can be modeled by a tangential force on the contact surface as

$$F_R = \mu R(z, \dot{z})\text{sgn}(\dot{\theta}_1 - \dot{\theta}_2)\chi(z) \tag{13}$$

where $\mu$ is the Coulomb friction coefficient, $\text{sgn}(\cdot)$ is the unit signum function, and $\chi(\cdot)$ is the unit step function representing the separation of the brake pad from the brake disk. We have the torques $T_i$ on $\theta_i$ $(i = 1, 2, 3)$ as

$$T_1 = r_bF_R - c_1|\dot{\theta}_1|\dot{\theta}_1,$$

$$T_2 = -r_bF_R,$$

$$T_3 = F_{\theta_3} = \rho R(z, \dot{z}), \tag{14}$$

where $c_1$ is the coefficient of the quadratic resistance including aerodynamic force on the wheel (or $\theta_1$). Table 2 summarizes the parameters of the FCM and quadratic resistance. Note that the value of the spring coefficient listed in Table 2 can be obtained approximately from a medium-carbon steel rod (Young’s modulus 205 GPa) of $5 \times 10^{-2}$ m diameter and 0.5 m length.

Therefore, we derive the dynamic model of the FCWIP as the wheeled double pendulum in (7) with the braking torque in (14).

### 2.3 Numerical examples

Figure 3 shows a numerical solution of the FCWIP model obtained by solving (2), (7), and (14) from the trivial initial state $\theta_1(0) = \theta_2(0) = 0, \theta_3(0) = \eta$ (or...

Table 2 Parameters of the FCM.

| Parameters          | Values                  |
|---------------------|-------------------------|
| $r_b$ | radius of brake disk  | 0.18 m                   |
| $\rho$ | cam ratio              | 1/20                     |
| $k_b$ | spring coefficient of the brake | $8 \times 10^4$ N/m |
| $c_b$ | viscous coefficient of the brake | $(2 \times 10^4$ Ns/m) |
| $\mu$ | Coulomb friction coefficient of the brake | 0.249                     |
| $\eta$ | offset of the brake mechanism | $(2 \times 10^{-4}$ rad) |
| $c_i$ | coefficient of quadratic resistance on the wheel | $(5 \times 10^{-4}$ Nms$^2$) |

Parentheses around values denote nominal values.

![Fig. 3 Time responses of the FCWIP for the condition listed in Tables 1 and 2.](image)

z(0) = 0, and $\dot{\theta}_i(0) = 0$ (i = 1, 2, 3). The parameter values are listed in Table 1 and 2 that are empirically chosen to achieve a stable standing motion. For numerical integration, a fourth-order Runge-Kutta-Gill method is employed with a time step of 10$^{-3}$.

As shown in Fig. 3, the FCWIP model becomes asymptotically stable under the suitable parameter condition. In this example, the angle of the first pendulum $\theta_2(t)$ converges to a small negative value representing a standing position that is slightly slanted toward the upside of the slope. Consequently, the angle of the second pendulum $\theta_3(t)$ converges to a small positive value that represents it hanging from the first pendulum to produce the brake force $F_R$ in (13). Moreover, the descent velocity of the wheel $\dot{\theta}_1(t)$ converges to 9.46 rad/s (6.81 km/h in translational velocity).

Figure 4 shows the sets of initial angles $\theta_2(0), \theta_3(0)$ of the first and second pendulums, respectively. The other initial values are set as $\theta_1(0) = \dot{\theta}_1(0) = 0$ (i = 1, 2, 3). The area hatched in gray is the set of initial angles from which the state converges to fallen positions of the FCWIP model, and the white area surrounded by the hatched area is the set that converges to the steady standing state, as shown in Fig. 3. From Fig. 4, it appears that the set of the initial angles that belongs to the standing position forms a mostly connected area. Therefore, it can be expected that the proposed FCWIP model exhibits some robustness against disturbance of the initial angles.

Considering potential real-life applications of the proposed system, dependencies of the parameters on the size of the attraction basin that belongs to the standing position could be a crucial problem. This will be addressed in a future study.

3 Steady-state analysis

3.1 State-space representation

For a simple expression, we perform a time scale transformation $t := qt^*$, where $q$ is a time scale and $t^*$ is nondimensional time. Taking a state vector:

$$
\begin{align*}
    x := (\theta_1, \theta_2, \theta_3 - \eta, q\dot{\theta}_1, q\dot{\theta}_2, q\dot{\theta}_3)^T, \\
    \dot{x} := d\theta_i/dt, \\
    \mathcal{M}(x) := \text{diag}\left( E_3, M(x) \right), \\
    f(x) := \begin{pmatrix} x_4 \\ x_5 \\ x_6 \\ q^2F(x) \end{pmatrix}, \\
    \tau(x) := \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \\
    q^2T(x) \end{align*}
$$

where $M(x), F(x), T(x)$ are the matrix and vectors in the dynamic model (7) and (14) via (15), and $E_3$ is a $3 \times 3$ identity matrix.

We choose $q := (k_b\rho^2)^{-1/2}$ to normalize the spring coefficient $k_b$ and introduce nondimensional parameters listed in Table 3. In this case, the components of the vectors in (18) are obtained as

$$
\begin{align*}
    q^2F_1 &= -Q_3r(x_5 + x_6)^2\sin(\eta + x_2 + x_3 - \alpha) \\
    &+ Q_4x_5^2\sin(x_2 + \alpha) + g^*Q_1\sin(\alpha), \\
    q^2F_2 &= -Q_3x_6(2x_5 + x_6)\sin(\eta + x_3) \\
    &- g^*(Q_1\sin(x_2 + x_3) - Q_4\sin(x_2)), \\
    q^2F_3 &= Q_3x_5^2\sin(\eta + x_3) - g^*Q_4\sin(\eta + x_2 + x_3),
\end{align*}
$$

![Fig. 4 Attraction basin of the stable steady state in Fig. 3.](image)
Table 3 Nondimensional parameters.

| Parameters      | Values          | Definition                  |
|-----------------|-----------------|----------------------------|
| $q$ time scale  | $200^{-1/2}$    | $k_p^{*} p^{1/2}$           |
| $k_p^{*}$ spring coefficient | 1               | $(q^2 p^2) k_p^{*}$        |
| $g^*$ acceleration of gravity | $4.9 \times 10^{-2}$ | $(q^2 g)$                  |
| $\mu^*$ Coulomb friction coefficient | (0.8964) | $(r_b \rho^{-1}) \mu$ |
| $c_b^*$ viscous coefficient | (3.536) | $(q_b)^2 c_b^{*}$ |

The values are transformed from the original parameters in Tables 1 and 2. Parentheses around values denote nominal values.

and

$$\begin{cases}
q^2 T_1 &= -\mu^* \sigma x_4 \chi(x_3) \{x_3 + c_b^* x_6\} \\
& - c_1 |x_4| x_4, \\
q^2 T_2 &= \mu^* \sigma x_5 \chi(x_3) \{x_3 + c_b^* x_6\}, \\
q^2 T_3 &= - \{x_3 + c_b^* x_6\}.
\end{cases} \tag{20}$$

3.2 Assumption of steady state

In view of the numerical example presented in Fig. 3, we consider a steady state $x^*$ of the FCWIP model (16) that satisfies

$$\ddot{x} = \dot{x}^* := (\omega, 0, 0, 0, 0, 0)^T, \quad \omega > 0 \text{ (constant)}. \tag{21}$$

The steady state $x^*$ mentioned above describes the rotation of the wheel down the slope with a constant angular velocity $x_4^* = \omega > 0$ while the first and second pendulum maintain certain steady angles $x_2^*$ and $x_5^*$, respectively, with $x_2^* = x_6^* = 0$. The angles $x_2^*$ and $x_3^*$ are assumed to satisfy the following conditions:

(A) $x_2^* < 0$: the first pendulum reaches a standing position (slightly) slanted to the upside of the slope.

(B) $x_3^* > 0$ (or $z^* > 0$): due to (A), the second pendulum hangs from the first pendulum (due to gravity and while maintaining $x_2^* < 0$) to produce the brake force $F_R$ in (13).

These conditions are required to stabilize the first pendulum in a standing position. Because, they guarantee existence of the braking force $F_R$ caused by a negative clearance between the brake pad and disk, $x_3^* > 0$ (or $z^* > 0$), and that is mechanically caused by $x_2^* < 0$. Otherwise, the braking force vanishes, and the FCWIP becomes nothing more than an uncontrolled wheeled double pendulum that can never be stabilized around the standing position.

In addition, note that the FCWIP model, in absence of the floor model of the slope, can theoretically have another stable steady state, a static equilibrium where the second pendulum is hanging down at rest at $x_2^* = \pi + \epsilon_2$ and $x_3^* = \epsilon_3$ for small $\epsilon_2, \epsilon_3 > 0$.

3.3 Steady-state equation

The steady-state equation is given by

$$\dot{x}^* = \mathcal{M}(x^*)^{-1} \left\{ f(x^*) + \tau(x^*) \right\}, \tag{22}$$

where the derivative $\dot{x}^*$ is the constant vector already defined in (21) and $x^*$ is an unknown vector representing the steady state. Multiplying both the sides by $\mathcal{M}(x^*)$, we obtain

$$f(x^*) + \tau(x^*) = \mathcal{M}(x^*) \dot{x}^* = \text{diag}(E_3, M(x^*)) \dot{x}^* = \ddot{x}^* \tag{23}$$

where the last equality is due to the zero components of $\dot{x}^* := (\omega, 0, 0, 0, 0, 0)$. Therefore, the steady-state condition is obtained as follows:

$$x_1^* = \omega, \quad x_5^* = x_6^* = 0, \tag{24}$$

$$0 = q^2 F_1 + q^2 T_1 = g^* Q_1 \sin(\alpha) - c_1 \omega^2 - \mu^* x_3^*, \tag{25}$$

$$0 = q^2 F_2 + q^2 T_2 = -g^* \{Q_3 \sin(\eta + x_4^* + x_5^*) - Q_4 \sin(x_4^*)\} + \mu^* x_3^*, \tag{26}$$

$$0 = q^2 F_3 + q^2 T_3 = -g^* Q_5 \sin(\eta + x_4^* + x_5^*) - x_3^*, \tag{27}$$

where $|x_3^*| x_4^* = \omega^2$ and $\sigma (x_1^* - x_5^*) \chi(x_5^*) = 1$ are substituted according to the assumption: $x_4^* - x_5^* = x_4^* = 0 > 0$ and $x_3^* > 0$ in Section 3.2.

Note that the equations (25), (26), and (27) represent the balance of the torque from the brake force and the gravity force at about $\theta_1, \theta_2$, and $\theta_3$, respectively. In particular, (25) can also be derived from the balance of the energy supply from the gravitational potential and the energy consumption via Coulomb friction and quadratic resistance.

The steady-state equations in (24), (25), (26), and (27) can be reduced to the following form:

$$\begin{cases}
x_1^* = \omega, \\
x_5^* = x_6^* = 0, \\
c_1 (x_4^*)^2 = g^* Q_3 \sin(\alpha) - \mu^* x_3^* > 0, \\
\sin(x_5^*) = -\frac{(1 + \mu^*) x_5^*}{g^* Q_4}, \\
\sin(x_5^* + x_4^* + \eta) = -\frac{x_5^*}{g^* Q_3}.
\end{cases} \tag{28}$$

Thus, we have derived the steady-state equations of the FCWIP model with three unknowns $x_3^*, x_5^*,$ and $x_4^* (= \omega)$. Note that the angle of the wheel in the steady state $x_4^*(t) \propto \omega t$ never appears explicitly in these steady-state equations.
It is clear from (28) that under the given mechanical structure and environment, the nontrivial components of steady state \((x_2^*, x_3^*, x_4^*)\) depend on three parameters, namely \(\mu^*, \eta, \) and \(c_1\). More precisely, \(x_2^*\) and \(x_3^*\) can be solved independently of \(x_4^*\), and they depend on the nondimensional friction \(\mu^*\) and the offset \(\eta\) of the FCM. After that, \(x_4^*\) is obtained as a function of \(x_3^*\) depending on \(c_1\).

### 3.4 Jacobian matrix at steady state

We consider a variation \(\delta x\) of \(x\) around \(x^*\) as \(x := x^* + \delta x\) and substitute it into the state-space model (16) as \(M(x^* + \delta x)(\dot{x}^* + \delta \dot{x}) = (f + \tau)(x^* + \delta x)\). The \(i\)th component of the left side can be written by the Einstein notation as

\[
L_i = M_{ij}(x^* + \delta x)\{\dot{x}_j^* + \delta \dot{x}_j\}
\]

\[
= [M_{ij}(x^*) + \frac{\partial M_{ij}}{\partial x_k}\delta x_k\} \{\dot{x}_j^* + \delta \dot{x}_j\} + O(\delta x, \delta \dot{x})^2
\]

\[
= M_{ij}(x^*)\dot{x}_j^* + M_{ij}(x^*)\delta \dot{x}_j
\]

\[
+ \frac{\partial M_{ij}}{\partial x_k}\delta x_k\dot{x}_j^* + O(\delta x, \delta \dot{x})^2.
\]

Due to the structures of \(M = \text{diag}(E_3, M)\) and \(x^* = (\omega, 0, 0, 0, 0, 0)^T\), we have

\[
\frac{\partial M_{ij}}{\partial x_k}\delta x_k\dot{x}_j^* = 0 = \begin{bmatrix} 0 & \frac{\partial M_{ij}}{\partial x_k}\delta x_k \cdot 0 \end{bmatrix} \delta x_j\]

for all \(i\) and \(j\). Therefore, neglecting the second and higher order term of \(\delta x\) and \(\delta \dot{x}\), we arrive at a variation equation of (16) as

\[
\delta \dot{x} = M(x^*)^{-1}\{Df(x^*) + D\tau(x^*)\}\delta x =: J(x^*)\delta x,
\]

where \(Df(x^*)\) denotes the Jacobian matrix of \(f(x)\) around \(x^*\) and \(J(x^*)\) provides a closed-loop state matrix whose eigenvalues represent the stabilities of the FCWIP model. The components of \(J(x^*)\) are given by

\[
Df(x^*) = \begin{bmatrix} 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & g^*Q_4C_1 - g^*Q_3C_2 - g^*Q_3C_2 \ 0 & 0 \\ 0 & -g^*Q_3C_2 - g^*Q_3C_2 \ 0 & 0 \\ \end{bmatrix},
\]

where \(C_1^* := \cos(x_2^*), \ C_2^* := \cos(x_2^* + x_3^* + \eta), \) and

\[
D\tau(x^*) = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -\mu^* - 2c_1x_4^* - c_2^* \mu^* \\ 0 & \mu^* & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ \end{bmatrix}.
\]

To obtain (32) and (33), \(|x_4^*| = x_2^*\) and \(\text{sgn}(x_4^* - x_5)\chi(x_3) = 1\) are assumed, because \(x_4(t) > 0, x_4(t) > 0, \) and \(x_4(t) - x_5(t) > 0\) hold for \(x_i(t) = x_i^* + \delta x_i(t), \ |\delta x_i(t)| \ll 1 \) \((i = 1, \ldots, 6)\).

The results in (32) and (33) imply that the stability of the FCWIP model depends on the nondimensional viscous coefficient \(c_b^*\) in addition to the parameters \(\mu^*, \eta, \text{ and } c_1\) that determine the steady states \((x_2^*, x_3^*, x_4^*)\).

In summary, we have found that under a given mechanical structure and environment,

- the steady angles \((x_2^*, x_3^*)\) depend on \((\mu^*, \eta)\),
- the steady descent velocity \(x_4^*\) depends on \((\mu^*, \eta, c_1)\), and
- the stability depends on \((\mu^*, \eta, c_1, c_b^*)\).

### 3.5 Eigenvalue equation

It can be proved that \(\text{rank } [J(x^*)] = 5 < 6 = \text{dim } x\), which follows from the assumption of the uniform motion \(\dot{x}_1(t) = \omega\). Thus, the characteristic equation of \(J(x^*)\) is given in the following form:

\[
\text{det}(J(x^*) - \lambda E_6) = \lambda h(\lambda) = 0,
\]

\[
h(\lambda) = \lambda^5 + a_1\lambda^4 + a_2\lambda^3 + a_3\lambda^2 + a_4\lambda + a_5,
\]

where \(\text{det}(-)\) denotes a determinant and \(E_6\) is a 6 \times 6 identity matrix. For simplicity, we refer to \(h(\lambda) = 0\) as an eigenvalue equation of the FCWIP model.

Therefore, the steady state \(x^*\) becomes stable if the maximal real part of the eigenvalues is negative, that is

\[
\Lambda := \text{Re } \lambda_{\text{max}} < 0, \quad \lambda_{\text{max}} := \arg \max_{\lambda} \text{Re } \lambda,
\]

where \(\lambda_i \ (i = 1, \ldots, 5)\) are the roots of \(h(\lambda) = 0\).

### 4 Critical points of steady state

As mentioned in Section 3.4, the stabilities of the steady state \(x^*\) depend on \(\mu^*, \eta, c_1, \) and \(c_b^*\). Here, we provide some numerical examples of that dependency. Thus, the parameter values are set to those listed in Table 1, 2, and 3 by default unless otherwise noted.
4.1 Dependency on $\mu^*$ and $\eta$

We first examine the dependency on the nondimensional friction $\mu^*$ and the offset $\eta$, which determine the steady angles $x_i^*$ as functions of the nondimensional friction $\mu^*$. $\Lambda$ and $x_i^*$ are obtained from numerical solutions of (28) by Newton’s method and (36), respectively. The solid line in the top graph represents $\Lambda$ and the solid and dotted lines in the bottom graph represent stable and unstable $x_i^*$, respectively. The values of $x_i^*$ ($i = 2, 3$) are scaled to share a common vertical axis.

Figure 5 shows the maximal real part of the eigenvalue $\Lambda$ and the nontrivial components $x_i^*$ as functions of the nondimensional friction $\mu^*$. $\Lambda$ and $x_i^*$ are obtained from numerical solutions of (28) by Newton’s method and (36), respectively. The solid line in the top graph represents $\Lambda$, and the solid and dotted lines in the bottom graph represent stable and unstable $x_i^*$, respectively. The values of $x_i^*$ ($i = 2, 3$) are scaled to share a common vertical axis.

It is clear from Fig. 5 that three types of critical points $P_0$, $P_1$, and $P_2$ appear, which are denoted as open circles, filled circles, and a triangle, respectively. $P_0$ gives an infimum inf$_{\mu^*} x_1^* = 0$ of the descent velocity $x_1^* > 0$, $P_1$ gives a stability boundary, and $P_2$ gives a folded (nonsmooth) minimum of $\Lambda(\mu^*)$.

To characterize these points, Fig. 6 plots the root loci of $h(\lambda) = 0$ in (35) along the steady states $x^*$ in Fig. 5. It can be numerically proven that under the considered condition, the eigenvalue equation $h(\lambda) = 0$ has three real roots and a pair of complex conjugate roots as

$$\lambda_0 = s_0, \lambda_{1\pm} = s_1 \pm j\Omega, \lambda_2 = s_2, \lambda_3 = s_3,$$

where $s_i, \Omega$ are real numbers and $j := \sqrt{-1}$. Among the five roots, only the first three roots $\lambda_0, \lambda_{1+}$, and $\lambda_{1-}$ affect the stability change, and only these three roots appear in the range of Fig. 6.

On the basis of the root loci obtained in Fig. 6, we can characterize the critical points in terms of eigenvalue types as follows:

- (P0): $P_0$ is a point such that $\lambda_{\text{max}} = 0$.
- (P1): $P_1$ is a Hopf bifurcation point, for which the loci cross the imaginary axis at $\lambda_{\text{max}} = \pm j\Omega$, where $\Omega$ is an angular frequency of a limit cycle.
- (P2): $P_2$ is a point such that maximal real root $s_0$ and the real part of the complex conjugate roots $s_1$ coincide, at which point they switch roles to produce the maximal real part.

Physically speaking, $P_0$ and $P_1$ provide stability limits, and $P_2$ maximizes the total stability or minimizes the time constant of the FCWIP model. The descent velocity vanishes ($x_1^* = 0$) at $P_0$ in this case, and a self-excited oscillation (limit cycle) emerges for $\Lambda(\mu^*) > 0$ near $P_1$.

Figure 7 (a) shows the limit cycle for $\mu^* = 1.01$ immediately after the Hopf bifurcation point $P_1$. Under this condition, the FCWIP model descends the slope in a standing position while the angles of the pendulums oscillate slightly and periodically. As this limit cycle is stable, $P_1$ is identified as a Hopf bifurcation point. In
general, a limit cycle occurs because of the temporal presence of negative resistance (i.e., negative energy consumption per unit time). In our problem, this is given by the braking torque $T_2$ in (20) multiplied by the friction velocity $(x_4 - x_3)$, specifically as

$$ D = T_2 \cdot (x_4 - x_3) $$

$$ = q^{-2} \mu^* \text{sgn}(x_4 - x_3) \chi(x_3)(x_3 + c_b^* \rho) \cdot (x_4 - x_3) $$

$$ = q^{-2} \mu^* |x_4 - x_3| \chi(x_3)(x_3 + c_b^* \rho) $$

$$ =: C \chi(x_3)(x_3 + c_b^* \rho) \quad (C > 0), \quad (38) $$

where $\text{sgn}(x_3)x = |x|$ is applied. As $\chi(x_3)$ is a step function, $D < 0$ occurs when $x_3 \geq 0$ and $x_3 + c_b^* \rho < 0$.

This implies that when $D < 0$, the brake pad (see Fig. 2 recalling $z = \rho x_3$, $\dot{z} = (\rho/q) x_4$) will be released with a velocity less than $x_3 < -x_3/c_b^* \leq 0$ while the pad is still pressed against the disk $(x_3 \geq 0)$. Figure 7 (b) shows the energy consumption $D$ along the limit cycle as a function of $x_3$, which numerically confirms the presence of $D < 0$. During this negative energy consumption, the cycle comes across the deadband border $x_3 = z = 0$. At this point, the step function $\chi(x_3)$ jumps from 1 to 0. This causes the $D$ to jump from a negative to a positive value, similar to $x_6$.

Figure 8 (a) shows the result as functions of the offset $\eta$ for $\mu^* = 0.97$. In this case, a Hopf bifurcation point $P_1$ does not appear in the plotted range $\eta > 0$. Outside this range, $x_3^*$ and $x_4^*$ vanish at $\eta = 0$ and violate the physical assumptions $x_2^* < 0$ and $x_4^* > 0$ for $\eta < 0$.

### 4.2 Dependency on $c_1$ and $c_b^*$

Figure 8 (b) shows the results as functions of the quadratic resistance $c_1$. It is clear that all the critical points $P_0$, $P_1$, and $P_2$ appear, although $x_2^*$ and $x_4^*$ become constant here because $c_1$ only affects $x_4^*$, as already discussed in (28).

However, the physical results of $P_0$ are different. That is, $P_0$ (or $\lambda_{\text{max}} = 0$) on $A(\mu^*)$ in Fig. 5 corresponds to the descent velocity at rest $x_4^* = 0$. In contrast, $P_0$ on $A(c_1)$ in Fig. 8 (b) corresponds to the infinite descent velocity $x_4^* \to \infty$ ($c_1 \to 0$). This can be explained by the second equation in (28), which is hyperbolic with respect to $c_1$ and $x_4^*$:

$$ c_1 (x_4^*)^2 = g^* Q_4 \sin(\alpha) - \mu^* x_3^* =: \bar{C} > 0. \quad (39) $$

This equation exhibits the following features:

- The right side of (39) (e.g., $\bar{C}$) is expected to be constant because $x_3^*$ is determined independently of (39).
- The left side $c_1 (x_4^*)^2$ vanishes at $P_0$ (or $\lambda_{\text{max}} = 0$), as will be discussed in Section 5.1.1.

The second feature $c_1 (x_4^*)^2 = 0$ holds when $c_1 = 0$ and/or $x_4^* = 0$. The latter condition $x_4^* = 0$ directly explains $P_0$ in Fig. 5 for a constant $c_1 > 0$. On the other hand, $P_0$ in Fig. 8 (b) can be explained by the limit $c_1 \to 0$ that causes $x_4^* = \sqrt{\bar{C}/c_1} \to \infty$ for the constant $\bar{C}$. In addition, these different $P_0$ can also be explained physically. That is, the condition $c_1 (x_4^*)^2 = 0$ results in vanishing of the quadratic resistance force $c_1 |x_4^*| x_4^* = 0$. This can be caused by the mechanism at rest $x_4^* = 0$ as well as by the absence of the effect of the quadratic resistance $c_1 = 0$.

Figure 8 (c) plots the result for the nondimensional viscous coefficient $c_b^*$ of the FCM. It is found that only the Hopf bifurcation point $P_1$ appears. Moreover, it appears that $x_4^* (i = 1, 2, 3)$ are all constant because the steady-state equation in (28) is independent of $c_b^*$, which only
affects the components of the Jacobian matrix as $\mp c_h^* \mu^*$ and $-c_h^*$ in (33).

5 Stability limits

Finally, we numerically continue the critical points in two-parameter planes to characterize the stability limits of the FCWIP model.

5.1 Conditions of the critical points

5.1.1 Zero quadratic resistance

The condition of $P_0$ (or $\lambda_{\text{max}} = 0$) is mathematically equivalent to $a_5 = 0$ in the eigenvalue equation (35). It follows that

$$0 = a_5 = \det \mathcal{M}^{-1} \cdot 2c_1 x_4^* g^* \times \{-C_1^* Q_4 - C_2^* Q_3 (C_1^* g^* Q_4 - (1 + \mu^*))\} \iff 0 = c_1 x_4^* \{C_1^* Q_4 + C_2^* Q_3 (C_1^* g^* Q_4 - (1 + \mu^*))\} \iff c_1 x_4^* = 0 \iff c_1 = 0 \text{ or } x_4^* = 0 \iff c_1 (x_4^*)^2 = 0. \quad (40)$$

Therefore, it is mathematically shown that the sufficient condition for $P_0$ (or $\lambda_{\text{max}} = 0$) is given by the zero quadratic resistance $c_1 (x_4^*)^2 = 0$.

As discussed in Section 4.2, the condition $P_0$ (or $c_1(x_4^*)^2 = 0$) causes two distinct descent velocities: $x_4^* = 0$ for $c_1 > 0$ and $x_4^* = \infty$ for $c_1 = 0$. Therefore, we denote them as $P_0^0$ and $P_0^\infty$, respectively, in the following sections.

The condition of $P_0^0$ is given by (39) with $c_1(x_4^*)^2 = 0$, from which we can eliminate $x_2^*$ and $x_3^*$ to obtain

$$\Phi_0 := \eta + \arcsin \frac{Q_1 \sin \alpha}{Q_3 \mu^*} + \frac{g^* Q_1 \sin \alpha}{\mu^*} - \arcsin \frac{Q_1 (1 + \mu^*) \sin \alpha}{Q_4 \mu^*} = 0. \quad (41)$$

On the other hand, $P_0^\infty$ is simply given by $c_1 = 0$. Because the condition (41) does not contain $x_2^*$ and $x_3^*$, the zero quadratic resistance points $P_0^0$ and $P_0^\infty$ are determined independently of the pendulum angles $x_2^*$ and $x_3^*$.

5.1.2 Hopf bifurcation

The condition $P_1$ (or $\lambda_{\text{max}} = \pm j \Omega$) for a Hopf bifurcation point is given by $\Re h(j \Omega) = \Im h(j \Omega) = 0$. On eliminating $\Omega$ from them, we obtain

$$\Phi_1 := a_5 \{a_4 (-a_2 a_2 a_2 + a_3^2 + a_4^2) + (-a_2 a_3 + a_1 (a_2^2 - 2a_4)) a_6^2 + a_3^2\} = 0 \quad (42)$$

for the Hopf bifurcation point. It is implied from (42) that $P_1$ coincides with $P_0^0$ (or $P_0^\infty$) because $a_5 = 0$ for $P_0^0$ (or $P_0^\infty$) leads to $\Phi_1 = 0$.

Note that, rigorously speaking, the above condition provides only a necessary condition of a Hopf bifurcation point; however, it leads to satisfactory results in the present analysis.

5.1.3 Minimal time constant

We numerically detect the condition of $P_2$ for the minimal time constant that satisfies

$$|s_0 - s_1| < 10^{-9} \quad (43)$$

where $s_0$ is the maximal real eigenvalue and $s_1$ is the real part of the complex conjugate eigenvalues, as defined in (37). In numerical calculations, the parameter values considered are swept to detect a point that satisfies (43), where the point in the first detection is taken as the point detected.

Note that we attempted to derive an equation for the minimal time constant in a closed form of $a_1, \ldots, a_5$ based on a given form of eigenvalue equation: $h(\lambda) = (\lambda - \lambda_{\text{max}})(\lambda - \lambda_{\text{max}} - j \nu)(\lambda - \lambda_{\text{max}} + j \nu)(\lambda^2 + p \lambda + q)$, however, the result was very weak to detect $P_2$ precisely. Therefore, in this paper, we employ the numerical method mentioned above, although another approach would be possible for an analytical expression of $P_2$.

5.2 Numerical continuation of the critical points

Figure 9 plots the sets of the critical points $P_0^0, P_1, P_2$ on two-parameter planes obtained from the numerical solutions of (41), (42), and (43) under (28). The results on the $(\mu^*, \eta), (\mu^*, c_1)$, and $(\mu^*, c_2^*)$ planes are labeled (a), (b), and (c) respectively in Fig. 9. The solid line denotes the set of the zero quadratic resistance point $P_0^0$ for $x_4^* = 0$, the dotted line denotes the set of the Hopf bifurcation point $P_1$, and the chained line denotes the set of the minimal time constant point $P_2$. The plots of $P_0^\infty$ for $c_1 = 0$ do not appear in the ranges of these plots. The hatched areas represent the stable regions of the steady state satisfying $\lambda < 0$ in (36).

It is clearly seen in Fig. 9 that the stable regions are bounded by $P_0^0$ and $P_1$ and that the minimal time constant point $P_2$ is sandwiched between them. Note
Continuation of the critical points

that in Fig. 9 (a), the plots are bounded by the assumption \( \eta > 0 \) and that in Fig. 9 (b) and (c), \( P_0^0 \) lies along the vertical line at \( \mu^* = \bar{\mu}^* \approx 0.89474 \). This is because \( P_0^0 \) is determined independently of \( c_1 \) and \( c_0^* \) in (41). Moreover, it appears that the critical points \( P_0^0, P_1, \) and \( P_2 \) tend to coincide as \( \mu^* \) increases on the \((\mu^*, \eta)\) plane, as \( c_0^* \) increases and decreases on the \((\mu^*, c_1)\) plane, and as \( c_1 \) increases on the \((\mu^*, c_1)\) plane. In contrast, as \( c_1 \) decreases on the \((\mu^*, c_1)\) plane, \( P_1 \) and \( P_2 \) also tend to coincide but they approach \( c_1 = 0 \) or \( P_0^\infty \) instead of \( P_0^0 \). As discussed in Section 5.1.2, the convergence between \( P_0^0 \) (or \( P_0^\infty \)) and \( P_1 \) can be explained by (42), in which the condition \( \Phi = 0 \) for the Hopf bifurcation point \( P_1 \) contains \( a_5 = 0 \) for the zero quadratic resistance point \( P_0^0 \) (or \( P_0^\infty \)). As shown in Fig. 10, however, it can be numerically proven that a purely imaginary eigenvalue \( \lambda_{max} = j\Omega \) along \( P_1 \) does not vanish even when \( P_1 \) coincides with \( P_0^0 \) (or \( P_0^\infty \)) in the parameter planes. Therefore, the Hopf bifurcation point \( P_1 \) does not degenerate and double-zero eigenvalues never arise at that point.

From an engineering viewpoint, the results obtained above imply that the FCWIP model allows a certain amount of tolerance in parameter settings because the stable conditions are obtained as simply connected finite areas. This suggests the possibility that the proposed mechanism can work even if there are some manufacturing errors. Furthermore, the stable area on the \((\mu^*, \eta)\) plane in Fig. 9 (a) forms a monotonically increasing shape, which implies that the offset \( \eta \) can be designed to shift the stable range of the friction coefficient \( \mu^* \).

5.3 Numerical evaluation of the descent velocity

In view of engineering applications, the descent velocity (or angular velocity of the wheel) \( x_4^* \) must be adjusted to a value suitable for the intended use. Figure 11 shows the values of \( x_4^* \) mapped into a gray scale within the stable areas on the parameter planes in Fig. 9. \( x_4^* \) values are numerically obtained by solving (28).

It is clear from Fig. 11 that \( x_4^* \) tends toward zero as the parameter conditions approach \( P_0^0 \) (solid lines), which is in agreement with the definition of \( P_0^0 \). Especially, in Fig. 11 (b), it is also clarified that \( x_4^* \) is diverging as the condition approaches \( P_0^\infty \) or \( c_1 = 0 \). Moreover, it appears that \( x_4^* \) changes smoothly and monotonically with the variations of the parameters. This suggests that one can adjust the descent velocity \( x_4^* \) by continuously shifting the parameters. However, it is also observed in Fig. 11 (b) that a sufficiently large value of the quadratic resistance \( c_1 \) is required to stabilize the mechanism because although a range of \( \mu^* \) exists for small \( x_4^* \) near \( \mu^* = \bar{\mu}^* \approx 0.89474 \), it narrows significantly as \( c_1 \) decreases. In addition, it appears in Fig. 11 (c) that \( x_4^* \) does not depend on \( c_0^* \), as discussed in the last paragraph in Section 3.4.
Then, we found three types of critical points in the parameter planes: (a) for the \((\mu^*, \eta)\) plane; (b) for the \((\mu^*, c_1)\) plane; and (c) for the \((\mu^*, c_2^*)\) plane.

Finally, we conducted numerical continuations of these points on the two-parameter planes and evaluated the descent velocity to obtain the following results:

- The stable conditions are obtained as simply connected finite areas on the parameter planes, bounded by \(P_0^0\) and \(P_1\).
- The minimal time constant point \(P_2\) is sandwiched between \(P_0^0\) and \(P_1\).
- The descent velocity \(x_4^*\) changes smoothly and monotonically with the parameter variations.

The abovementioned results lead to the conclusion that the parameter selection to design the FCWIP mechanism stabilized on a slope will not be highly sensitive, at least in theory.

In future work, we plan to develop a physical FCWIP mechanism. For this purpose, we will introduce stick-slip effects into the friction term in our model and investigate the effect on the stabilities. We also plan to conduct stochastic analysis on the FCWIP model to consider robustness against random disturbances and random parameter fluctuations.
